Background: AML treatment in elderly patients (pts) >60 years (y) with intensive chemotherapy (IC) or azacitidine (AZA) are not necessarily mutually exclusive. **Aims:** Results of the multicenter DRKS00004519 (RAS-AZIC) study of the East German Study Group (OSHO) which evaluated first-line treatment with AZA followed by response-based AZA or IC in pts >60y with AML are presented.

Methods: pts >60y with newly diagnosed AML (n=112) were included. Recruitment was completed in May, 2016. In the phase I part, safety of upfront AZA (75mg/m^2/day s.c) for 7 days followed by IC (mitoxantrone 10mg/m^2/day on day (d) 1-3 and cytarabine 1g/m^2/BID on d 1, 3, 5, 7) on d17 was established through a 3+3 design. In the multicenter phase II part (figure), upfront AZA was sequentially followed by AZA or IC based on d15 bone marrow (BM) blasts (<45 *vs* ≥45%) and CR/CRi on d56 which were both previously identified as early predictors for long-term response to AZA in AML (Al-Ali *et al. Leuk Lymph* 2012). The primary endpoint was response (OR) [CR/CRi, and PR] at d90 according to the International Working Group criteria. Based on the optimal two-stage design (Simon. *Control Clin Trials* 1989), protocol treatment was non-inferior to standard IC if, on an intention-to-treat basis, an OR of 61% was reached. Adverse events (AEs) were reported according to the NCI CTCAE 4.03. All pts gave written informed consent.

Results: Median age was 70y (52% males). *de novo* AML was present in 65% of pts. Median BM blasts and WBC were 50% and 4.4x10^9/L respectively. Genetic risk was high in 30%, intermediate in 55%, and favorable in 15%. *FLT3* and *NPM1* were mutated in 12% and 22% respectively. All pts received first-line AZA. Only lower baseline blasts correlated with blasts <45% on d15 (*p<0.0005*). Yet, 40% of pts with baseline blasts >50% reached this goal. Protocol assigned treatment on d15 was applied to 101 (90.2%) pts (54.5% continued with AZA; 46.5% received IC). Of 152 AZA cycles given till d56, 33.6% were applied in an outpatient setting. Until d90, one IC cycle was needed in 77 (68.8%) pts. In the intention-to-treat cohort (n=112), OR and mortality at d90 were 62.5% [CR/CRi (n=43%/15%); PR (4.5%)] and 8.9% respectively. The probabilities of achieving CR/CRi with AZA alone, two AZA cycles + one IC, and one AZA cycle + one IC were 28.3%; 53.3%, and 58.3% respectively. Age, WBC, and type of AML had no impact on response in the three treatment scenarios. Similarly, response was not influenced by baseline BM blasts. CR/CRi was lower in high risk genetics (48%) compared to other risk categories (78%) (*p=0.007*). This negative association was particularly marked in pts with high-risk genetics and d15 BM blasts >45% [CR/CRi 38.5% *vs* 84% in other genetic categories (p=0.009)]. Interestingly, the impact of genetics on OR was not seen in the two AZA cycles + one IC cohort (p=1.0). CR with AZA alone was remarkably high (70%) in pts with favorable genetics including those with *NPM1mut*/*FLT3wt* (*p=0.003*). Protocol therapy was generally well tolerated. Constipation grade 1+2 was the most frequently reported AE under AZA (48%). The most frequent grade 3+4 non-hematologic AE was infection [IC (47%); AZA (20%)].

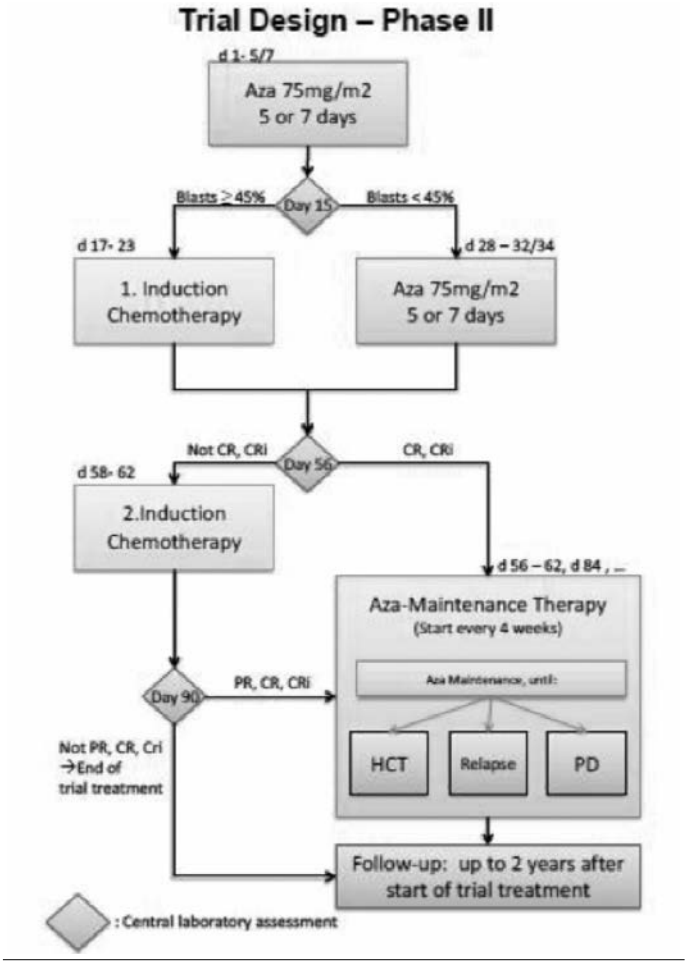

Figure 1.

Summary/Conclusions: Sequential response-based epigenetic and chemotherapy in elderly pts with AML is safe, associated with low mortality, and yields non-inferior responses compared to repeated cycles of IC. Marrow blasts d15 after the first AZA cycle and genetics could guide treatment-decision. The follow-up of this trial will scrutinize the impact of this approach on survival.

P556

OVERALL SURVIVAL WITH CPX-351 *VERSUS* 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, THERAPY-RELATED ACUTE MYELOID LEUKEMIA: SUBGROUP ANALYSIS OF A PHASE 3 STUDY

J.E. Lancet[1,*], D. Rizzieri[2], G.J. Schiller[3], R.K. Stuart[4], J.E. Kolitz[5], S.R. Solomon[6], L.F. Newell[7], H. Erba[8], G.L. Uy[9], R. Ryan[10], M. Chiarella[10], A.C. Louie[10], J.E. Cortes[11]

[1]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [2]Duke Comprehensive Cancer Center, Durham, NC, [3]David Geffen School of Medicine/UCLA, Los Angeles, CA, [4]Medical Univ. of South Carolina & Hollings Cancer Center, Charleston, SC, [5]Monter Cancer Center, Northwell Health system, Lake Success, NY, [6]BMT Group of Georgia, Atlanta, GA, [7]Oregon Health and Science Univ, Portland, OR, [8]Univ. of Alabama at Birmingham, Birmingham, AL, [9]Washington Univ. School of Medicine, St. Louis, MO, [10]Jazz Pharmaceuticals, Palo Alto, CA, [11]MD Anderson Cancer Center, Houston, TX, United States

Background: Therapy-related acute myeloid leukemia (tAML) may occur as

a late complication of cytotoxic or radiation therapy and is associated with a poor prognosis. CPX-351 is a liposomal formulation that delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin. In a randomized, open-label, controlled phase 3 trial in patients aged 60 to 75 years with newly diagnosed, secondary AML (eg, tAML or AML after myelodysplastic syndrome), CPX-351 significantly improved overall survival (OS) *versus* cytarabine/daunorubicin (7+3).

Aims: The current analysis of this phase 3 study evaluated outcomes in the subgroup of patients with tAML.

Methods: Enrolled patients were randomized 1:1 to receive induction with 1 to 2 cycles of CPX-351 (100 units/m^2 [cytarabine 100mg/m^2 + daunorubicin 44mg/m^2] on Days 1, 3, and 5 [2nd induction: Days 1 and 3 only]) or 7+3 (cytarabine 100mg/m^2/day x 7 days [2nd induction: x 5 days] + daunorubicin 60mg/m^2 on Days 1, 2, and 3 [2nd induction: Days 1 and 2 only]). Patients who achieved complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 cycles of consolidation therapy. Note, the study was not powered for this subgroup analysis.

Results: A total of 304 patients were enrolled and received study treatment, including 62 (20%) patients with tAML (CPX-351 arm, n=30; 7+3 arm, n=32). Characteristics of tAML patients were similar between the CPX-351 and 7+3 arms: median age was 69.0 *versus* 67.5 years, and 47% *versus* 53% were male. Prior treatment in patients with tAML included prior non-anthracycline chemotherapy alone (26%), radiation alone (26%), non-anthracycline chemotherapy + radiation (32%), non-anthracycline + anthracycline chemotherapy (5%), and non-anthracycline + anthracycline chemotherapy + radiation (11%). CPX-351 was associated with a significant OS benefit *versus* 7+3 in older tAML patients and numerically longer event-free survival and remission duration (Figure). Additionally, a greater proportion of tAML patients in the CPX-351 arm *versus* the 7+3 arm achieved CR+CRi (47% *vs* 36%, respectively; odds ratio=1.33 [95% CI: 0.47, 3.81]) and proceeded to stem cell transplantation (37% *vs* 27%; odds ratio=1.54 [95% CI: 0.53, 4.49). Serious treatment-emergent adverse events (TEAEs) were reported for 18/30 (60%) of tAML patients in the CPX-351 arm and 12/32 (38%) of tAML patients in the 7+3 arm; the observed difference in serious TEAEs in this subpopulation appeared to primarily be due to the incidence of febrile neutropenia (n=6/30 [20%] *vs* n=0/32 [0%]). Three (10%) patients in the CPX-351 arm and 5 (16%) patients in the 7+3 arm experienced a TEAE that resulted in death during the treatment period; there was no pattern in the individual TEAEs that led to death.

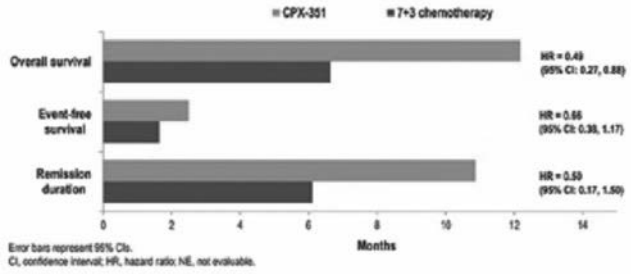

Figure 1.

Summary/Conclusions: CPX-351 is associated with improved efficacy and a safety profile comparable to 7+3 in older patients with newly diagnosed tAML. Outcomes in the tAML subgroup mirrored the overall study population, indicating CPX-351 may represent a new therapeutic option for this difficult to treat population.

P557

HYPERFERRITINEMIA IS AN INDEPENDENT POOR PROGNOSTIC FACTOR IN ACUTE MYELOID LEUKEMIA

S. Bertoli[1,2,3,*], X. Thomas[4], E. Bérard[5,6], F. Vergez[2,3,7], S. Tavitian[1], M.-V. Larcher[4], E. Delabesse[2,3,7], A. Sarry[1], J. Monfray[8], F. Huguet[1], M. Michallet[4], R. Christian[1,2,3]

Background: The prognostic impact of ferritinemia has been studied in myelodysplastic syndromes and acute myeloid leukemia (AML) patients undergoing allogeneic stem cell transplantation (SCT). In this context, high levels of serum ferritin have been correlated to a shorter overall survival (OS) and an increased relapse risk.. We have previously shown that hyperferritinemia at diagnosis has a strong prognostic impact in a cohort of 162 AML patients with intermediate cytogenetic risk and younger than 60.

Aims: We now extend the analysis to all age and cytogenetic risk, in order to confirm the impact of hyperferritinemia in AML.

Methods: This study included 525 adult AML patients (excluding acute promyelocytic leukemia) treated by intensive chemotherapy in Toulouse and Lyon University Hospitals between January 1st, 2005 and December 31st, 2014 who had ferritinemia documented at AML diagnosis. Ferritin level was measured by spectrophotometry. Primary outcome was disease-free survival (DFS). To avoid the loss of information and the reduction in power introduced by the categorization of ferritinemia and to deal with the non-linearity in the relationship between outcomes and ferritinemia, we explored the relationship between ferritinemia and outcomes using restricted cubic spline.

Results: Median age at diagnosis was 59.4 years (interquartile range [IQR], 47.8-66.4); 303 of them (57.7%) were men. Disease status was *de novo* in 83.2% (N=437). Median white blood cell count (WBC) was 10.0x10^9/L (IQR, 2.5-41.5). Cytogenetic risk was favorable, intermediate and adverse in 9.2 (N=48), 71.8 (N=374) and 19% (N=99) respectively; ELN classification was favorable, intermediate-I, intermediate-II, adverse and unknown in 21.0 (N=110), 25.5 (N=134), 22.3 (N=117), 18.9 (N=99) and 12.4% (N=65) respectively. Median ferritinemia at AML diagnosis was 715 µg/L (IQR, 372-1304), ranging from 34µg/L to 70759 µg/L (upper normal limit [UNL]: 300µg/l). 421 patients achieved complete remission (CR; 80.2%). Early death and treatment failure rates were 7.8% (N=41) and 12% (N=63) respectively. 169 patients underwent allogeneic HSCT in first CR (32.2%). Median DFS was 19.8 months (IQR, 8.4-Not Reached). Ferritinemia had a significant impact on DFS: median DFS was 21.2 months in patients with ferritinemia ≤2100 µg/L (7-fold UNL), and 12.7 months with ferritinemia >2100 µg/L (HR, 1.6 [95%CI, 1.1-2.3], p=0.0253). After adjustment for age, AML status and cytogenetics or ELN classification, relapse or death rate significantly (p=0.0122) increased from ferritinemia superior or equal to 2141 µg/L (Figure 1). Ferritinemia had also a significant impact on early deaths, CR rate, EFS and OS after adjustment (≥4-fold UNL, p<0.0001; ≥7-fold UNL, p=0.004; ≥3-fold UNL, p<0.0001 and ≥3-fold UNL, p<0.0001 respectively).

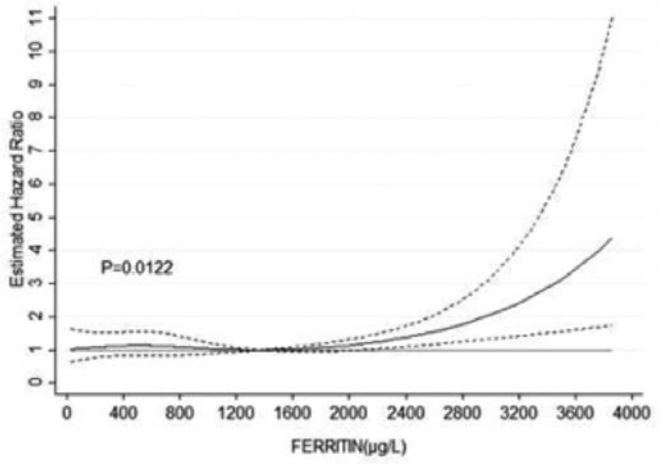

Figure 1.

Summary/Conclusions: In conclusion, hyperferritinemia is a prognostic marker independent from well-acknowledged factors, such as cytogenetics and molecular abnormalities. Ferritinemia should be included at AML diagnosis workup as it provides reproducible information on short and long-term outcome for AML patients of any subgroup. The putative link between hyperferritinemia, inflammation and chemoresistance should be investigated.

P558

NGS ANALYSIS OF 474 BONE MARROW SAMPLES FROM 157 AML PATIENTS TREATED WITH AZACITIDINE–IMPACT OF AGE ON MUTATIONAL LOAD

L. Pleyer[1,2,3,*], F.J. Gassner[1,2], S. Burgstaller[4], H. Wedler[5], T.N. Hartmann[1,2,3], B. Jansko[1], D. Neureiter[6], J. Thaler[4], R. Greil[1,2,3]

[1]Oncologic Center, Paracelsus Medical University, [2]Salzburg Cancer Research Institute (SCRI), Center for Clinical Cancer and Immunology Trials, [3]Cancer Cluster, Salzburg, [4]Department of Internal Medicine IVDepartment of Internal Medicine IV, Klinikum WelsGrieskirchen, Wels, [5]Qiagen Genomic Services, Qiagen GmbH, Hilden, [6]Institute of Pathology, Paracelsus Medical University, Salzburg, Austria

Background: Recent publications have shown the prognostic value of performing molecular analyses in patients (pts) with acute myeloid leukaemia (AML) (Papaemmanuil et al, NEJM 2016). While recent data has been published on pts with myelodysplastic syndromes (MDS) and AML treated with decitabine, (Welch et al, NEJM 2016; Duncavage et al, Blood 2017) data on

AML pts treated with azacitidine (AZA) has only been presented in abstract form thus far (Tang et al, ASH 2016). Data on the impact of age on mutational load in AML are scarce.
Aims: To assess the mutational landscape in elderly AML pts treated with AZA; specifically, whether age has an impact on mutational load.
Methods: We analysed 474 bone marrow FFPE specimens from 157 AML pts in the Austrian Registry of Hypomethylating Agents from two centres (Salzburg, Wels-Grieskirchen) using a 53-gene panel (all exons). NGS was performed by Qiagen. Minimum coverage: 1.500x. All mutations were checked against COSMIC-v79, ClinVar, ICGC, DoCM, dbsnp and Varsome databases. For comparison of categorial variables Chi-squared test was used, for comparison of means Students T-test was used.
Results: The rate of secondary (s)AML was significantly lower in pts <75 (n=85), *vs* ≥75 years (n=54) (66.0 *vs* 77.8%, P<0.001). There was no significant difference in the rate of adverse cytogenetics or monosomal karyotype before AZA treatment between pts < *vs* ≥75 years, respectively (data not shown). Mutational load (average number of mutated genes and mutations per pt) assessed at/before initiation of AZA, was significantly higher in pts <75 *vs* pts ≥75 years (10.2 *vs* 8.6 mutated genes/pt; P=0.030 and 12.9 *vs* 10.5 mutations/pt; P=0.012; Figure 1A). This also held true when mutational load was assessed at any timepoint during the course of AML (including during/post-AZA treatment) (Figure 1B). In total, 139 pts had more than one marrow sample with NGS results. Analysis of paired samples revealed that mutational load was significantly higher during/post-AZA *vs* before AZA in both age groups (Figure 1C-D). In total, 60.4%, 15.8%, 8.6%, 3.6% and 11.5% of pts acquired 0, 1, 2, 3, 4-13 additional mutations, respectively. No relevant differences between pts < *vs* ≥75 years were found (data not shown). When comparing the delta of mutations before *vs* during/after AZA according to age group, no significant difference was found (Figure 1E).

Table 1.

Figure 1. Impact of age on mutational load in AML patients treated with azacitidine

1A (total cohorts)	Before AZA		
	<75 years	>=75 years	P-value
n pts. in cohort	85	54	n.a.
Mutated genes per pt., median (avg) [range]	9,0 (10,2) [3-28]	8,0 (8,6) [3-21]	0,030
Mutations per pt., median (avg) [range]	11,0 (12,9) [3-34]	10,0 (10,5) [4-25]	0,012

1B (total cohorts)	During the course of the disease		
	<75 years	>=75 years	P-value
n pts. in cohort	94	63	n.a.
Mutated genes per pt., median (avg) [range]	10,0 (11,0) [3-31]	10,0 (9,3) [3-21]	0,011
Mutations per pt., median (avg) [range]	12,0 (13,9) [3-40]	11,0 (11,4) [4-25]	0,008

1C (paired samples)	Before AZA vs during the course of the disease		
	<75 years		
	Before AZA	During disease	P-value
n pts. in cohort	85	85	n.a.
Mutated genes per pt., median (avg) [range]	9,0 (10,2) [3-28]	10,0 (11,2) [3-21]	<0,001
Mutations per pt., median (avg) [range]	11,0 (12,9) [3-34]	13,0 (14,2) [3-40]	<0,001

1D (paired samples)	Before AZA vs during the course of the disease		
	≥75 years		
	Before AZA	During disease	P-value
n pts. in cohort	54	54	n.a.
Mutated genes per pt., median (avg) [range]	8,0 (8,6) [3-21]	9,0 (9,3) [3-21]	0,004
Mutations per pt., median (avg) [range]	10,0 (10,5) [4-25]	11,0 (11,4) [4-25]	0,004

1E	Before AZA vs during the course of the disease		
	<75 years	≥75 years	P-value
n pts. with BM samples before & during/after AZA	85	54	n.a.
Delta mutated genes per pt., median (avg) [range]	0 (1,0) [0-8]	0 (0,6) [0-9]	0,157
Delta mutations per pt., median (avg) [range]	0 (1,3) [0-11]	0 (0,9) [0-13]	0,349

Summary/Conclusions: The observed mutational load per pt in our cohort is higher than that observed by others using targeted re-sequencing methods, which report an average of only 2-4 mutations per pt (Duncavage et al, Blood 2017; Conte et al, Leuk 2013; Au et al, Diagn Pathol 2016; Grove & Vassiliou, Dis Model Mech 2014). It seems however, that a higher mutational load (average: 13-14 [range 1-51]) per pt can be found using whole genome/whole exome sequencing (The Cancer Genome Atlas Research Network, NEJM 2013; Merlevede et al, Nat Commun 2016). We hypothesize that the higher observed number of mutations in our study may be due to the high coverage (minimum 1.500x) we used (most previous publications had a median/average coverage of ≤500x). While age <75 years seems to coincide with a higher mutational load both before AZA start and during/after AZA in our cohort, it does not seem to predispose to the acquisition of more mutations during/after AZA. Higher mutational load in AML pts <75 years did not go hand in hand with a higher rate of known/presumed adverse prognostic baseline factors such as adverse cytogenetics, monosomal karyotype, or sAML at AZA start. We thus hypothesize that the biology of the disease may generally be more aggressive in younger pts. Correlation analyses of age and mutational load with response and survival will be in our final presentation.

P559

PROGNOSTIC VALUE OF EARLY WT 1 RESPONSE IN AML PATIENTS UNDERGOING INTENSIVE CHEMOTHERAPY

S. Machherndl-Spandl[1,*], T. Vockenhuber[1], M. Binder[1], O. Zach[1], M. Girschikofsky[1], P. Bettelheim[1], A. Weltermann[1]
[1]Internal Medicine I, Ordensklinikum Elisabethinen Linz, Linz, Austria

Background: Monitoring minimal residual disease based on quantitative PCR represents an important risk stratification tool in acute myeloid leukemia (AML) and enables the prediction of impending relapse. Besides common fusion genes and mutated genes, Wilms tumor 1 (WT1) gene is widely used to follow *de novo* AML.
Aims: The aim of our study was to evaluate the relevance of WT1 expression for the prognosis of patients with AML in a real life population.
Methods: Bone marrow samples from 174 consecutive adult AML patients (18-85 years) were used for WT1 mRNA quantification. APL patients were excluded. Of 143 patients with WT1 overexpression at diagnosis, those treated with intensive induction chemotherapy and achieving haematological remission after the first cycle of therapy were included in the retrospective follow-up analysis (n=129).
Results: The extent of WT1 expression at diagnosis had no prognostic relevance. In contrast, achievement of low WT1 levels after induction chemotherapy was associated with a significant better overall (OS) and disease free survival (DFS) as compared to persistent high WT1 expression at hCR1: 5 years OS 54% *vs* 0% (p<0.001); DFS 44% *vs* 0% (p<0.001). Additionally, compared with patients with a low WT-1 reduction (<5 log) at hCR1, the relative risk of death was 0.32 (95% CI 0.1-0.7) in patients with intermediate WT-1 reduction (5-8 log) and 0.15 (95% CI 0-0.05) in patients with high WT-1 reduction (>8 log), after adjustment for age, ELN-risk group, and stem cell transplantation in CR1. The corresponding 5-years OS for patients with low, intermediate and high WT-reduction were 10%, 42% and 71% (p<0.001), respectively. Even though numbers of patients were small (n=33), SCT at CR1 seems to overcome the adverse risk of persistent WT1 expression: DFS 5.3 years (0-12.9) for patients with SCT and 0.7 years (0.6-0.9) for patients without SCT (p=0.004).
Summary/Conclusions: Persisting WT1 expression in AML patients achieving a CR1 after induction chemotherapy is a strong, independent predictor for DFS and OS in patients with AML. Since 80–90% of AML patients exhibit WT1 overexpression at diagnosis, this marker is widely applicable for early risk re-evaluation and corresponding therapy adaption.

P560

EVALUATION OF THE IMPACT OF SIGNAL RATIO ON OVERALL SURVIVAL IN FLT3-MUTATION-POSITIVE RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA FOLLOWING ONCE-DAILY TREATMENT WITH GILTERITINIB

M. Levis[1,*], J. Altman[2], A. Perl[3], J. Cortes[4], C. Smith[5], M. Litzow[6], J. Hill[7], R. Larson[8], C. Liu[7], E. Ritchie[9], S. Strickland[10], E. Wang[11], A. Neubauer[12], G. Martinelli[13], E. Bahceci[7]
[1]John Hopkins University, Baltimore, [2]Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, [3]University of Pennsylvania-Abramson Comprehensive Cancer Center, Philadelphia, PA, [4]University of Texas MD Anderson Cancer Center, Houston, TX, [5]University of California-San Francisco, San Francisco, CA, [6]Mayo Clinic, Rochester, MN, [7]Astellas Pharma US Inc., Northbrook, IL, [8]University of Chicago, Chicago, [9]Weill Cornell Medical College, New York, NY, [10]Vanderbilt-Ingram Cancer Center, Nashville, TN, [11]Roswell Park Cancer Institute, Buffalo, NY, United States, [12]Universitatsklinikum Giessen und Marburg, Marburg, Germany, [13]Seragnoli Institute of Hematology, Bologna, Italy

Background: Fms-like tyrosine kinase 3 (FLT3) internal tandem duplications (ITD) in acute myeloid leukemia (AML) are associated with early relapse and short survival, particularly in the context of high allelic burden. Patients with high FLT3-ITD signal ratio are particularly sensitive to FLT3 inhibitors but the clinical effects of allelic burden on survival have not been validated in trials of these drugs. Gilteritinib is a highly specific, potent FLT3/AXL inhibitor with demonstrated activity against both FLT3-ITD and tyrosine kinase domain (TKD) mutations. A recent Phase 1/2 study (CHRYSALIS; NCT02014558) demonstrated that FLT3 mutation-positive ($FLT3^{mut+}$) patients with relapsed/refractory (R/R) AML treated with gilteritinib had high clinical response rates and prolonged overall survival (OS), especially at doses ≥80mg/d.
Aims: To evaluate the effect of FLT3-ITD and FLT3-TKD signal ratios on OS in $FLT3^{mut+}$R/R AML patients who had received gilteritinib doses ≥80mg/d.
Methods: Signal ratios were assessed in adult $FLT3^{mut+}$R/R AML patients who had received gilteritinib doses ≥80mg/d. Genomic DNA extraction and PCR with fluorescent primers were used to generate transcripts of *FLT3* alleles containing ITD and TKD mutations. *FLT3* alleles containing ITD mutations generated transcripts >330 bp in length. For TKD mutations, primers on either side of the TKD region were used to amplify the target region and an EcoRV endonuclease digest was performed. *FLT3* alleles containing TKD mutations generated shorter (130 bp) transcripts due to the lack of an EcoRV restriction site typically

present in the wild-type allele. Differential fluorescence detection enabled identification of the specific transcripts. Median ITD signal ratio (ie, FLT3-ITD:wild-type FLT3) was calculated from patients with ITD mutations (with/without concomitant TKD mutations); median TKD signal ratio (*i.e.*, FLT3-TKD:wild-type FLT3) was calculated from all patients with a TKD mutation. Median OS estimates were derived and stratified based on ITD and TKD signal ratios that fell above or below median signal ratio values reported for the trial.
Results: Signal ratio was assessed in 152 patients with FLT3-ITD and -TKD mutations who had received ≥80mg gilteritinib. Of these patients, 136 had FLT3-ITD mutations with or without concomitant TKD mutations, and 16 had FLT3-TKD mutations only. Median ITD and TKD signal ratios were 0.84 and 0.5, respectively. Patients with FLT3-ITD signal ratios that were above or below the median ITD signal ratio had OS durations of 216 and 213 days, respectively. No significant difference in median OS was observed between patients in the highest and lowest FLT3-ITD signal ratio quartiles (**Figure 1**). Patients with TKD signal ratios that were above the median value (0.5) had a median OS of 202 days; those with TKD signal ratios below the median value had significantly shorter median OS of 33.5 days (*P*=.0004; **Figure 1**).

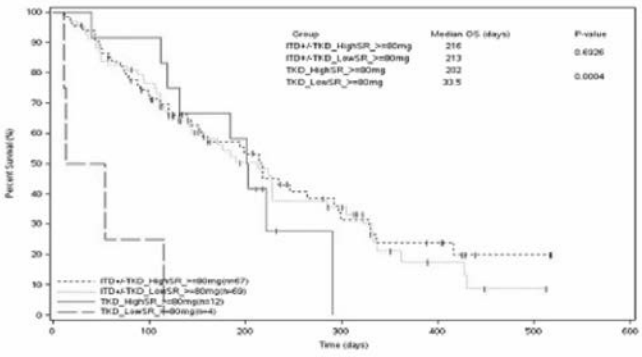

Figure 1.

Summary/Conclusions: These data show that FLT3-ITD signal ratio has little impact on survival in patients with FLT3-ITD mutations who received gilteritinib. In the small number of patients with FLT3-TKD mutations only, high TKD signal ratio was associated with a longer OS, similar to that observed in patients with FLT3-ITD mutations. These data suggest a possibility that oncogene addiction in FLT3-TKD$^+$ R/R AML requires a high allelic burden and clonal dominance. Also, it is possible that FLT3-TKD signal ratio in R/R AML may contribute to the response rate in patients with FLT3-TKD mutations only. Further investigation is warranted.

P561

CLINICAL OUTCOME OF HYPOCELLULAR AML AND AML WITH MYELODYSPLASIA-RELATED CHANGE (MRC) COMPARED TO DE NOVO ADULT AML WITH NORMAL CELLULARITY AFTER HEMATOPOIETIC CELL TRANSPLANTATION

D.-H. Kwak[1,*], J.-H. Yoon[1], H.-J. Kim[1], S.-S. Park[1], S.-E. Lee[1], B.-S. Cho[1], K.-S. Eom[1], Y.-J. Kim[1], S. Lee[1], J.-W. Lee[1], W.-S. Min[1]
[1]Department of Hematology, Catholic Blood and Marrow Transplantation Center, Leukemia Research Institute, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Hypocellular acute myeloid leukemia (hypo-AML) and AML with myelodysplasia-related change (AML-MRC) accounts for small proportion of adult AML. As the characteristics and outcomes are not well recognized.
Aims: We tried to analyze these specific groups and compared to normocellular AML.
Methods: After exclusion of secondary AML, therapy-related AML, and AML M3, we retrospectively analyzed 1593 AML cases between 2002 and 2013. We found 101 (6.3%) patients with hypo-AML and 164 (10.3%) patients with *de novo* AML-MRC. Hypo-AML was diagnosed with blast counts ≥20% within hypocellular (<20%) bone marrow (BM) which was identified with at least two biopsy specimens and age-related correction was considered. *De novo* AML-MRC was defined with multilineage dysplasia ≥10% for each lineage with blast counts ≥20% without history of antecedent hematologic disease. Patients (n=20) with both AML-MRC and hypo-AML were distributed in AML-MRC group.
Results: Patients with hypo-AML were older (p<0.001) and significantly presented lower leukocyte and PB/BM blast counts (p<0.001). Patients with AML-MRC were older and lower hemoglobin level with lower PB/BM blast counts (p<0.001) compared to normocellular *de novo* AML. In both groups, the risk of karyotype was poorer. In untreated group (n=207), hypo-AML showed longer survival outcome compared to normocellular *de novo* AML and AML-MRC. In treated group (n=1386), hypo-AML and AML-MRC both showed higher relapse rate and inferior survival outcome compared to normocellular AML, and hypo-AML showed higher therapy-related mortality (TRM) rate. However, multivariate analysis showed that there were no significant differences between the three AML subgroups especially when the patients were treated with hematopoietic cell transplantation (HCT).

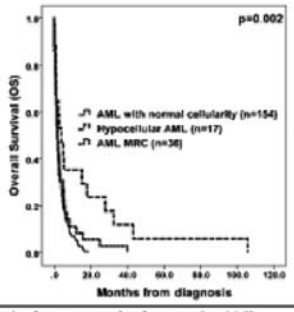

Figure 1. OS results in the untreated subgroup (n=207).

Figure 1.

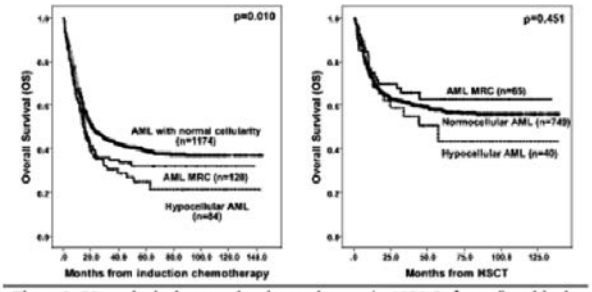

Figure 2. OS results in the treated patients subgroup (n=1386, Left panel) and in the HSCT treated subgroup (n=854, Right panel).

Figure 2.

Summary/Conclusions: The long-term outcome of hypo-AML and AML-MRC were poorer than normocellular *de novo* AML, mainly due to older age and large proportion of adverse-risk karyotype which caused unavailable condition for HCT.

P562

INITIAL RESULTS FROM A FIRST-IN-HUMAN STUDY OF IMGN779, A CD33-TARGETING ANTIBODY-DRUG CONJUGATE (ADC) WITH NOVEL DNA ALKYLATING ACTIVITY, IN PATIENTS WITH RELAPSED OR REFRACTORY AML

J. Cortes[1,*], D. DeAngelo[2], E. Wang[3], C. Arana-Yi[4], P. Zweidler-McKay[5], M. Munteanu[5], C. Andreu-Vieyra[5], H. Erba[6], W. Blum[7], E. Traer[8]
[1]MD Anderson Cancer Center, Houston, [2]Dana-Farber Cancer Institute, Boston, [3]Roswell Park Cancer Institute, Buffalo, [4]University of New Mexico Cancer Center, Albuquerque, [5]ImmunoGen, Inc., Waltham, [6]University of Alabama at Birmingham, Birmingham, [7]The Ohio State University, Columbus, [8]Oregon Health and Science University, Portland, United States

Background: Acute myeloid leukemia (AML) accounts for the highest number of leukemia deaths in the United States annually. IMGN779 is an ADC that binds with high affinity and specificity to CD33, a validated therapeutic target in AML. IMGN779 comprises a humanized anti-CD33 antibody attached via a cleavable linker to the novel DNA-interacting payload DGN462. Once released within the target cell, DGN462 exerts potent antitumor activity via DNA alkylation, without cross-linking, resulting in cell cycle arrest and apoptosis.
Aims: This Phase I study is designed to establish the maximum tolerated dose (MTD) and determine the recommended phase 2 dose (RP2D) of IMGN779 when administered to patients with CD33$^+$ AML. Evaluation of the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of IMGN779 are secondary objectives.
Methods: Adult patients (≥ 18 years) with relapsed or refractory CD33$^+$ AML (defined by ≥20% of AML blasts expressing CD33 by flow cytometry) were eligible for enrollment. Informed consent was obtained from all patients. Dose-escalation, which follows a standard 3+3 design, began with a starting dose of 0.02mg/kg. IMGN779 was administered intravenously once every 2 weeks on days 1 and 15 as part of a 28-day cycle. Adverse events (AEs) were evaluated using NCI-CTC v4.03.
Results: As of February 2017, a total of 17 patients (9 female, 8 male) with a median age of 62 years have received IMGN779 treatment. Five dose levels have been completed, with escalation proceeding from 0.02–0.26mg/kg. AEs were as expected for this relapsed/refractory AML population including cytopenias and constitutional symptoms. No relationship between frequency or sever-

ity of AEs and IMGN779 dose level was observed. The most common AEs were nausea (41%), febrile neutropenia (29%), and rash (29%); pneumonia, respiratory failure, and constipation were additional AEs reported in 4 or more patients (≥ 24%). The most common serious adverse events (SAEs) were grade 3 febrile neutropenia (29%) and pneumonia (24%). No dose limiting toxicities (DLTs) have been reported. Importantly, no safety signals regarding liver or hematopoietic toxicity have been observed in laboratory assessments. In general, plasma concentrations (Cmax) of IMGN779 increased relative to dose. In the highest cohort examined thus far (Cohort 5, 0.26mg/kg), sustained exposure (AUC) was observed in all patients through 48 hours post-infusion. A pharmacodynamics (PD) assay demonstrated consistent saturation of residual free CD33 in all Cohort 5 patients past 48 hours, consistent with the PK results. Initial response data will be presented.

Summary/Conclusions: This is the first clinical experience of the next generation CD33-targeting ADC, IMGN779, in AML patients. No DLTs have been noted to date. AEs were generally consistent with the underlying disease. PK and PD are favorable and dose escalation is continuing.

Aggressive Non-Hodgkin lymphoma - Relapsed/refractory

P563

COMBINATION OF TGR-1202, UBLITUXIMAB, AND BENDAMUSTINE IS SAFE AND HIGHLY ACTIVE IN PATIENTS WITH ADVANCED DLBCL AND FOLLICULAR LYMPHOMA

M.A. Lunning[1,*], P. Bierman[1], G.R. Bociek[1], M.T. Schreeder[2], T. Siddiqi[3], S. Blumel[1], K. Cutter[2], E.K. Pauli[2], D. Bui[3], P. Sportelli[4], H.P. Miskin[4], M. Purdom[4], M.S. Weiss[4], J.M. Vose[1]
[1]University of Nebraska Medical Center, Omaha, NE, [2]Clearview Cancer Institute, Huntsville, AL, [3]City of Hope National Medical Center, Duarte, CA, [4]TG Therapeutics, Inc., New York, NY, United States

Background: TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, active in patients (pts) with rel/ref hematologic malignancies that has demonstrated a notably differentiated safety profile, including in long-term follow up (Burris, 2016). Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. Bendamustine (Benda) is an active chemotherapy agent in pts with lymphoma. The combination of UTX + TGR-1202 is tolerable and active in pts with rel/ref hematologic malignancies and is under Phase 3 testing for patients with CLL and Phase 2b testing for patients with DLBCL.
Aims: This Phase 1 trial evaluates the safety and efficacy of UTX + TGR-1202 + Benda in pts with advanced Diffuse Large B-cell Lymphoma (DLBCL) and Follicular Lymphoma (FL).
Methods: Eligible pts had rel/ref DLBCL or FL with an ECOG PS ≤2 w/o limit to number of prior therapies. ANC of >750 and Platelets >50,000 was permitted. Pts refractory to prior PI3Kδ, Benda, or anti-CD20 therapy were eligible. UTX was dosed on Days 1, 8, 15 of Cycle 1, Day 1 of Cycle 2-6, followed by Cycle 9 & 12. TGR-1202 was started at 800mg QD with a -1 dose reduction cohort at 600mg if not tolerated in ≥2/6 pts. Benda was dosed at 90mg/m^2 on Days 1 & 2 of Cycles 1-6 only. Primary endpoints included safety and efficacy (Cheson 2007).
Results: Twenty-three pts were evaluable for safety: 15 diffuse large B-cell (DLBCL) and 8 follicular (FL). Med age 68 yo (range 31-81); 12 M/11 F; median prior treatment regimens=2 (range 1-6); 12 pts (52%) were refractory to their immediate prior treatment and to prior CD20 therapy, and 7 patients had progressed post-transplant. ECOG PS 0/1/2 (3/18/2). Initially 2/4 pts at 800mg TGR-1202 experienced AE's in Cycle 1 that led to treatment interruption (rash, neutropenia) thus the 600mg dose of TGR-1202 was explored. No additional Cycle 1 treatment delays were reported at the 600mg dose level, which was later expanded and the 800mg TGR-1202 dose is now being evaluated with stricter eligibility criteria to require an ANC of ≥ 1.0, and the use of growth factor support in cycle 1 is now encouraged. The most common AE's included diarrhea (39%; G3/4 4%), decreased appetite (35%; G3/4 4%), nausea (30%; G3/4 4%), asthenia (26%; G3/4 4%) and neutropenia (22%). The only Grade 3/4 AE reported in >10% of pts was neutropenia (22%). Two pts had a TGR-1202 dose reduction. Nineteen pts (11 DLBCL/8 FL) were evaluable for efficacy: ORR amongst all pts was 79% (15/19) with 42% (8/19) achieving a complete response (CR), of which 5 were DLBCL and 3 FL. ORR in the respective groups as follows:

Table 1.

Group	N	ORR (%)	CR N (%)	PR N (%)	SD N (%)
DLBCL	11	73%	5 (45%)	3 (27%)	1 (9%)
FL	8	88%	3 (38%)	4 (50%)	-

Median follow-up time on study is 6 mos for all pts (range 1–14+ mos).

Summary/Conclusions: The combination of UTX, TGR-1202, and bendamustine has exhibited manageable toxicity with significant activity in advanced DLBCL and FL pts including an encouraging 42% CR rate (45% in DLBCL and 38% in FL). Enrollment continues at the 800mg TGR-1202 dose level with the use of growth factor prophylaxis. Safety and efficacy data for all pts will be updated at the meeting. Based upon the early activity of the triplet, future registration directed studies are being planned.

P564

VENETOCLAX (VEN) IN PATIENTS WITH RELAPSED/REFRACTORY NON-HODGKIN LYMPHOMA (NHL)

M. S. Davids[1,*], A. W. Roberts[2], J. F. Seymour[3], W. G. Wierda[4], S. D. Puvvada[5], L. Gressick[6], D. Alter[6], L. Zhou[6], S. Y. Kim[6], M. Verdugo[6], J. F. Gerecitano[7]
[1]Dana-Farber Cancer Institute, Boston, United States, [2]Royal Melbourne Hospital, Parkville VIC, [3]Peter MacCallum Cancer Centre, East Melbourne VIC, [4]University of Texas MD Anderson Cancer Center, Houston, [5]University of Arizona Cancer center, Tucson, Australia, [6]AbbVie, Inc., North Chicago, [7]Memorial Sloan-Kettering Cancer Center, New York City, United States

Background: VEN is a selective orally bioavailable BCL-2 inhibitor. The dose-escalation Phase 1 study of VEN in 106 patients (pts) with relapsed/refractory NHL reported an ORR of 44%. Most pts had diffuse large B-cell/follicular lymphoma.
Aims: We report on updated results in pts with less common NHL subtypes.
Methods: VEN was administered and continued until progressive disease (PD)/unacceptable toxicity, in dose cohorts ranging from 300-1200mg. Adverse events (AEs) were assessed by NCI-CTCAE v4.0 and response by 2007 Cheson IWG response criteria, utilizing CT scans beginning at wk 6.
Results: 35 of 106 pts had mantle cell lymphoma (MCL, n=28), marginal zone lymphoma (MZL, n=3) or Waldenström macroglobulinemia (WM, n=4). Most common all grade treatment emergent AEs were nausea (51%), diarrhea (49%) and fatigue (34%); grade 3/4 AEs in >10% of pts were neutropenia and anemia (17% each). Laboratory TLS was reported in a single pt (bulky MCL). MCL pts (median age: 72 years) had received a median of 3 (1–7) prior treatments (tx). Median time from start of prior tx to start of VEN was 13 mo (2–148) and time on VEN was 11 mo (0.2-42). ORR was 75%, 6 pts (21%) achieved CR and remain on study (DORs: 25-40 mo). One pt with a PR proceeded to elective allogeneic stem cell transplant and remained disease free at last protocol defined follow-up (24 mo after coming off study). Median PFS was 11 mo and DOR was 15 mo. MZL pts (median age: 63 years) had received a median of 4 (2-6) prior tx. Time from start of prior tx to start of VEN was 8, 14, 73 mo and time on VEN was 5, 1, 35 mo. One pt (6 prior tx) received VEN for <1 mo due to progressive cytopenias; 1 pt (4 prior tx) achieved a PR with VEN at wk 6 but had PD at wk 16; 1 pt (2 prior tx) achieved PR at wk 6 and is the only pt to remain on study (DOR:32 mo). WM pts (median age: 67 years) had a median of 4 (3-5) prior tx. Time from start of prior tx to start of VEN was 5, 18, 33, 67 mo and time on VEN was 42, 17, 54, 20 mo. All pts achieved PR (at wks 6 [n=2], 16 and 36), with DORs of 11, 12, 38 and 50+ mo (latter is ongoing and remains on study).
Summary/Conclusions: VEN monotherapy has a tolerable safety profile in MCL, MZL and WM pts. ORR were high and most responses durable; median PFS and DOR suggest significant activity in MCL pts. Further investigation of VEN in each disease is indicated.

P565

WHOLE BODY DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING IS A GOOD PREDICTOR OF TREATMENT OUTCOME AFTER ONE CYCLE OF IMMUNOCHEMOTHERAPY IN AGGRESSIVE LYMPHOMA

K. De Paepe[1,*], F. De Keyser[1], C.-A. Van Keerberghen[2], O. Gheysens[2], P. Wolter[3], O. Bechter[3], D. Dierickx[4], A. Janssens[4], R. Oyen[1], G. Verhoef[4], V. Vandecaveye[1]
[1]Radiology, [2]Nuclear Medicine, [3]Medical Oncology, [4]Hematology, University Hospitals Leuven, Leuven, Belgium

Background: Early identification of non-Hodgkin lymphoma patients not responding to therapy may enable treatment adaptation which might impact on the prognosis and reduces exposure to ineffective drugs. Interim fluorodeoxyglucose-positron emission tomography/computed tomography (FDG-PET/CT) after 2-4 cycles of immunochemotherapy has prognostic value shown for some lymphomas, but its role in treatment adaption is still considered experimental. Disadvantages of this technique are the significant amount of false positive results due to a rituximab-induced inflammatory response as well as substantial patient radiation exposure.
Aims: To evaluate the use of whole body diffusion-weighted magnetic resonance imaging (WB-DWI/MRI) as an radiation-free imaging technique to predict treatment outcome in NHL after one cycle of ICT (2-3 weeks).
Methods: Forty-six patients with aggressive NHL (35 diffuse large B-cell lymphoma (DLCBL), 2 primary mediastinal B-cell lymphoma (BCL), 1 unclassifiable BCL, 1 Burkitt lymphoma, 4 Mantle cell lymphoma (MCL), 2 peripheral T-cell lymphoma (TCL) and 1 extranodal natural-killer TCL) were consecutively enrolled between 2011 and 2015. All patients had baseline and interim WB-DWI/MRI (after 1 cycle immunochemotherapy), and end-of-treatment FDG-PET/CT; 38/46 had an interim FDG-PET/CT. Additional International prognostic index (IPI), immunohistochemical markers Ki-67, Bcl-6 and Bcl-2 were evaluated for their predictive value. WB-DWI/MRI were assessed quantitatively with histogram analysis (both on high b-value signal intensity (b1000) and apparent diffusion coefficient (ADC)), and calculation of parameter changes between baseline and interim scan (Δpar). Statistical analysis consisted of Kaplan-Meier survival analysis univariate and multivariate Cox regression analysis with disease-free-survival (DFS) as outcome measure.
Results: Median follow-up time was 43 months (4-70 months). Thirty-three patients achieved complete remission (CR), 4 progressed and 9 had recurrent disease. Patients were non-responders according to WB-DWI/MRI in case of an ADC_{mean} decrease for lymphoid tissue or less than 10% $b1000_{mean}$ decrease in bone or a $b1000_{kurt}$ increase of less than 6% in extranodal lesions. WB-DWI/MRI predicted DFS correctly in 45/46 (96%) [p<0.001; hazard ratio (HR) 66.6, (CI 95% 8.5-523.2)]; end-of-treatment FDG-PET/CT was predictive in 37/46 (80%) [p=0.004; HR 5.1, (CI 95% 1.7-15.4)], and interim FDG-PET/CT in 27/38 (71%) [p=0.042; HR 3.5, (CI 95% 1.0-11.5)]. Nor IPI score neither histological or immunohistochemical parameters demonstrated a significant predictive value. Multivariate analysis revealed WB-DWI/MRI as the only independent prognostic factor (p<0.001).
Summary/Conclusions: WB-DWI/MRI can accurately predict treatment outcome in aggressive NHL after only one cycle of immunochemotherapy (2-3 weeks) without the burden of radiation exposure.

P566

CLINICAL OUTCOMES OF DIFFUSE LARGE B CELL LYMPHOMA, FOLLICULAR LYMPHOMA AND RICHTER'S TRANSFORMATION PATIENTS TREATED WITH IBRUTINIB: A REAL-WORLD EXPERIENCE OF OFF LABEL, IBRUTINIB USE.

K. Isaac[1,*], K. Kennard[2], S. Schuster[2], D. Landsburg[2], M. Hughes[2], J. Svoboda[2], S. Nasta[2], T. Latorre[2], W. Surkis[1], C. Dorsey[2], M. Fanning[2], E. Chatburn[2], C. Daniel[3], C. Timlin[2], J. Gill[2], A. Mato[2]
[1]Lankenau Medical Center, Wynnewood, [2]Abramson Cancer Center, Hospital of the University of Pennsylvania, [3]Hospital of the University of Pennsylvania, Philadelphia, United States

Background: Ibrutinib (IBR), a Bruton's Tyrosine Kinase (BTK) inhibitor, is FDA approved for chronic lymphocytic leukemia, Waldenstrom macroglobulinemia, marginal zone lymphoma and mantle cell lymphoma. Despite its limited data, IBR is increasingly being utilized as a treatment option for patients with relapsed/refractory (RR) diffuse large B-Cell lymphoma (DLBCL) and follicular lymphoma (FL).
Aims: To further characterize the efficacy of IBR in patients with RR DLBCL, Richter's transformation (RT) or FL.
Methods: We conducted a retrospective cohort study of DLBCL, RT and FL patients consecutively treated with IBR. Data collected included patient demographics, stage, IPI, genetic characteristics, prior treatments, IBR dose and duration, reasons for discontinuation, and response. PFS and OS were estimated using the Kaplan Meier method and survival analysis by the log rank (LR) test.
Results: 44 patients were identified (DLBCL: n=24, 54.5%; FL: n=12, 27%, RT: n=8, 18%) who received IBR monotherapy in the RR setting. Baseline characteristics included age (range 19–80), 61% male, 95% ECOG 0 - 1, 71% stage IV, 62% elevated LDH, and 48% R-IPI ≥ 4. DLBCL sub-types (Hans criteria) were 25% non-GC (n=11), 16% GC (n=7), and 14% unclassifiable (n=6). In the FL subgroup, 8% were grade 1, 58% were grade 2, 33% were grade 3a. Median number of prior therapies was 5 (range 1-11). All RT patients were not treated with IBR previously for CLL. The three most common reasons for IBR discontinuation were progression (35%), toxicity (20%), and bridge to CAR-T (10%). PFS and OS data are shown in Table 1. In DLBCL, cell of origin (IHC) did not impact outcomes (p=0.97, LR test). Patients with RT had better PFS as compared to *de novo* DLBCL (p=0.03, LR test).

Table 1.

Table 1: Survival data stratified by NHL Type

Subtype	Median PFS (months)	Median OS (months)
Entire cohort	3 (n = 41)	19 (n=41)
DLBCL (entire cohort)	1.1 (n = 21)	11.5 (n = 23)
DLBCL GC (CR + PR)	0.9	12
DLBCL Non-GC	1.1	7.6
RT	3 (n = 8)	15.6 (n = 8)
FL	10.5 (n = 12)	30.8 (n = 12)

Summary/Conclusions: In the largest single-center, real-world experience of IBR use in DLBCL, RT and FL, we validate findings reported in clinical trials. In FL, responses appear to be durable (median PFS of >10 months). Outcomes are extremely poor in DLBCL and use of IBR as monotherapy is not recommended. Perhaps IBR is best used as a short-term bridge to more definitive therapies. Cell of origin by immunohistochemistry does not predict PFS and should not be used to preferentially select non-GC DLBCL patients for IBR. Patients with RT appear to have more durable responses (*vs* DLBCL) suggesting differing dependence on BTK signaling for tumor survival.

P567

PREVALENCE AND PROGNOSTIC VALUE OF MYD88 AND CD79B MUTATIONS IN IMMUNE-PRIVILEGED SITE AND (EXTRA)NODAL DLBCLS

[1]Hematology, Leiden University Medical Center, Leiden, [2]Pathology, Academic Medical Center, Amsterdam, [3]Lymphoma and myeloma center Amsterdam, LYMMCARE, [4]Hematology, Academic Medical Center, Amsterdam, Amsterdam, [5]Biostatistics, Leiden University Medical Center, Leiden, [6]Internal Medicine&Hematology, Onze Lieve Vrouwe Gasthuis, Amsterdam, [7]Internal Medicine&Hematology, Albert Schweitzer Hospital, Dordrecht, [8]Internal Medicine&Hematology, Tergooi Hospital, Hilversum, [9]Internal Medicine&Hematology, Deventer Hospital, Deventer, [10]Internal Medicine&Hematology, Waterland Hospital, Purmerend, [11]Hematology, Antoni van Leeuwenhoekziekenhuis, Amsterdam, [12]Hematology, University Medical Centre Groningen, Groningen, [13]Pathology, Academic Medical Center, [14]Lymphoma and myeloma center, LYMMCARE, [15]Hematology, Academic Medical Center, Amsterdam, Netherlands

Background: Activating mutations in CD79B and MYD88 are important molecular drivers of a subset of diffuse large B-cell lymphomas (DLBCLs), activating the B-cell receptor and toll-like receptor pathways, respectively. Interestingly, the frequency of these mutations differs greatly among DLBCLs at different anatomical sites, with a remarkably high prevalence at immune-privileged (IP) sites (central nervous system and testis). Recent studies suggest that these mutations are associated with an unfavorable prognosis. However, the prognostic value in relation to the site of presentation has not yet been explored.
Aims: To investigate if mutations in MYD88 and CD79B are independent prognosticators for overall survival (OS) in DLBCL, particularly in patients with lymphomas at IP sites, for which a high prevalence of these mutations was reported.
Methods: In this retrospective study, we investigated a large clinically annotated cohort of 189 consecutive primary DLBCLs, including primarily nodal (N=64), primarily extranodal (N=74) and IP localizations (N=51). Patients were diagnosed between 1990-2015 at the Academic Medical Center, (University of Amsterdam) or other Dutch hospitals. The vast majority was treated with (R-) CHOP (N=143) or other immune-chemotherapies (N=16). Detailed clinical characteristics of all patients were collected. For all patients BCL2, BCL6, and MYC translocations, Epstein Bar Virus (EBV) status and the mutational status of MYD88 and CD79 were assessed, employing methods described previously (Kraan *et al.*, BCJ 2013).

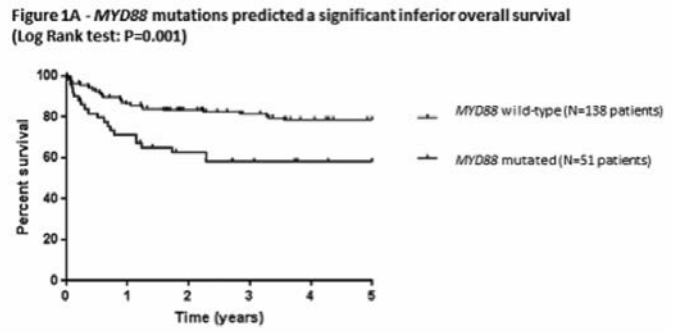

Figure 1.

Results: Translocations in BCL2, BCL6 and MYC were identified in 14, 32 and 13 patients, respectively and 23 EBV-positive cases were found. MYD88 and CD79B mutations were identified in 51 patients and 19 cases, respectively. Interestingly, there was hardly any overlap between the presence of translocations (BCL2, BCL6 and MYC) or EBV and that of MYD88 and/or CD79B mutations, indicating that these tumors represent distinct DLBLC subgroups. In accordance with previous studies, the incidence of MYD88 mutations was increased at IP sites (67%, Chi-square P=0.001), compared to nodal (13%) and other extranodal localizations (12%). In patients harboring a MYD88 mutation, we frequently found a coexisting CD79B mutation (N=14). Patients with a MYD88 mutation demonstrated a significantly inferior 5-years OS compared to DLBCL with wild-type MYD88 (Log Rank test (LR) P=0.001, Figure-1A). This prognostic significance was also found for DLBCLs with IP sites (Figure-1B, LR P=0.029). Coexistence of a CD79B mutation did not impact the prognostic significance of MYD88. Multivariable Cox regression analysis, including clinical and molecular characteristics (i.e. age, translocations, EBV, CD79B, etc.) identified MYD88, Ann Arbor Stage and localization (IP, nodal and extranodal) as independent prognostic parameters with Hazard ratios 1.8, 1.5 and 2.6, respectively (95% Confidence intervals: 1.0-3.6, 1.0-2.8 and 1.3-4.9, respectively).
Summary/Conclusions: Our study demonstrates that mutated MYD88 is an independent unfavorable prognostic factor for OS, in particular in DLBCL patients presenting at IP sites. These patients with MYD88 mutations display a relatively high prevalence of coexisting CD79B mutations. Interestingly, a recent study by Wilson *et al.* (Nat. Med. 2015), indicates that these patients are more sensitive to treatment with Bruton's Kinase inhibitors. Our study highlights the importance of investigating the mutational status of MYD88 and CD79B in larger prospective clinical trials with molecularly targeted agents, particularly in DLBCL patients with IP localizations.

HIV-INFECTED PATIENTS WITH RELAPSED NON-HODGKIN LYMPHOMA (NHL) OR HODGKIN LYMPHOMA (HL): RESULTS FROM THE GERMAN HIV-RELATED LYMPHOMA COHORT STUDY

P. Schommers[1], M. Hentrich[2,*], D. Gillor[1], C. Wyen[1], T. Wolf[3], J.-C. Wasmuth[4], J. Bogner[5], C. Spinner[6], S. Esser[7], B. Jensen[8], M. Müller[9], A. Schleicher[10], G. Fätkenheuer[1], C. Hoffmann[10]
[1]University of Cologne, Cologne, [2]Hematology/Oncology, Rotkreuzklinikum München GmbH, München, [3]University of Frankfurt, Frankfurt, [4]University of Bonn, Bonn, [5]University of Munich, [6]Klinikum rechts der Isar, München, [7]University of Essen, Essen, [8]University of Düsseldorf, Düsseldorf, [9]Vivantes Auguste-Viktoria Hospital, Berlin, [10]ICH Study Center, Hamburg, Germany

Background: The outcome of HIV-associated lymphoma has undergone significant improvement in recent years beginning with the widespread use of combination antiretroviral therapy (ART). However, among AIDS-related deaths, non-Hodgkin lymphoma (NHL) is the most frequent event. HIV-positive patients (pts) with relapsed NHL or Hodgkin lymphoma (HL)) should be treated in a manner similar to immunocompetent pts.
Aims: To analyze the outcome of pts with HIV-related lymphoma who experienced a relapse after having achieved a complete response to first line therapy.
Methods: This prospective multicenter cohort study includes adult HIV- 1 infected pts with biopsy or cytologically proven HIV-related lymphoma diagnosed at 32 participating centers in Germany and Austria since January 2005. Data on HIV-infection and lymphoma characteristics, treatments and outcomes were recorded. Pts with indolent lymphomas and primary central nervous system lymphomas were excluded from the present analysis.
Results: Of 499 pts (463 males, 36 females) 394 had aggressive NHL and 105 HL. The median age at lymphoma diagnosis was 45.6 yrs (range, 22–74.7). 344 pts (69%) were diagnosed with advanced stage (III/IV) lymphoma and the median CD4-cell count was 271/µl (266/µl in NHL and 287/µl in HL). As of June 2015, 311 of 499 pts (62%) achieved a documented CR, 235 (60%) with NHL and 76 (72%) with HL. After a median follow-up of 17 months for NHL and 30 months for HL pts, 31 of 235 NHL (13%) and 8 of 76 HL (11%) experienced a relapse. Incidence of relapse was 6.9/100 patient years (PY) within the 1st year after primary diagnosis and 1.3/100 PY thereafter (*P*=0.0062). Median time to relapse was 7.3 months in NHL and 18.0 months in HL. Relapses beyond 12 months occurred in 6 of 31 NHL cases (19%) and in all 8 HL cases (100%) (*P*=0.045). Median overall survival (OS) of all relapsed pts was 29.0 months (95% CI 14.1-44.2 months) after primary lymphoma diagnosis. In pts with HL, OS was not reached, whereas it was 15 months in pts with NHL (*P*=0,024). Regarding the entire cohort of 311 pts with a documented CR, the 2-year OS rate was 57% in pts with relapse as compared to 97% in those without (*P*<0.001). The majority of relapsed pts died of lymphoma (68%).
Summary/Conclusions: Relapses from CR are relatively rare in pts with HIV-associated NHL and HL. In pts with NHL the majority of relapses occur within the first year after primary diagnosis, whereas in HL most relapses occur beyond 12 months. Overall, pts with relapsed HIV-related NHL have a worse outcome than pts with relapsed HL.

P569

RISK STRATIFICATION BASED ON NCCN-IPI AT THE TIME OF DIAGNOSIS IN COMBINATION WITH POST-TREATMENT PET-CT SCAN FOR THE TREATMENT OF NODAL PERIPHERAL T-CELL LYMPHOMA

D.-H. Yang[1,*], H.-Y. Yhim[2], Y. Park[3], Y. H. Han[4], J. Choi[5], J.-H. Moon[6], H.-J. Shin[7], D. S. Kim[8], W. S. Lee[9], J. H. Lee[10], Y. R. Do[11], M. K. Kim[12], Y. S. Choi[13]

Medicine, Chonbuk National University Hospital, Jeonju, [5]Department of Nuclear Medicine, Korea University Anam Hospital College of Medicine, Seoul, [6]Department of Internal Medicine, Kyungpook National University Hospital, Daegu, [7]Department of Internal Medicine, Pusan National University Hospital, Busan, [8]Department of Internal Medicine, Korea Universiy Guro Hospital College of Medicine, Seoul, [9]Department of Internal Medicine, Inje University College of Medicine, Busan Paik Hospital, [10]Department of Internal Medicine, Dong-A university College of Medicine, Busan, [11]Department of Internal Medicine, Dongsan Medical Center, Keimyung University School of Medicine, [12]Department of Internal Medicine, Yeungnam University College of Medicine, Daegu, [13]Department of Internal Medicine, Chungnam National Unviersity Hospital, Daejeon, Korea, Republic Of

Background: Nodal peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of neoplasms, which include PTCL not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), anaplastic large-cell lymphoma-anaplastic lymphoma kinase positive (ALCL-ALK+), and ALCL-ALK-. Clinical assessments before and after treatment are essential to predict survival in nodal PTCL. However, limited data is available regarding the prognostic relevance of National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI) and post-treatment PET-CT scan.
Aims: The study investigated the prognostic significance of baseline NCCN-IPI and post-treatment PET-CT scan, assessed by Deauville score, in patients with nodal PTCL. The primary aim was to establish a risk model for nodal PTCL patients based on NCCN-IPI, a clinical tool, and post-treatment PET-CT scan indicating tumor viability.
Methods: In this retrospective cohort study, patients with newly diagnosed nodal PTCL were consecutively enrolled from 11 hospitals in South Korea. Patients were eligible if they were histologically diagnosed with nodal PTCL from Jan 2005 to June 2016, received systemic chemotherapy, and had the results of PET-CT scan at the time of diagnosis and at the end of treatment. Post-treatment PET-CT was assessed using 5-point Deauville score. The study excluded ALCL-ALK+ due to well-known better survival.
Results: A total of 396 patients were screened for eligibility. Seventy patients were excluded from the analysis due to following reasons: unavailable pre- or post-treatment PET scans, no systemic treatment, uncertain histology, and ALCL-ALK+. Thus, 326 patients were analyzed. The median age was 61 years (range, 18-86) and 209 (64%) were male. PTCL-NOS (N=172, 53%) was the most common subtype included, and AITL (N=111, 34%) and ALCL-ALK- (N=43, 13%) followed. Three-fourths of patients (N=242) had stage III/IV. Majority of patients received anthracycline-based therapy. Patients were categorized into low (N=42, 13%), low-intermediate (LI, N=108, 33%), high-intermediate (HI, N=136, 42%), and high (N=40, 12%) risk groups according to NCCN-IPI. Based on the Deauville criteria, post-treatment PET scan was scored as 1 (N=130, 40%), 2 (N=47, 14%), 3 (N=60, 18%), 4 (N=27, 8%), and 5 (N=62, 19%). Because the number of progression in Deauville score 3 (40/60, 67%) was significantly different from score 2 (21/47, 45%; *P*=0.023) and 4 (24/27, 89%; *P*=0.030), we categorized patients into 3 groups: Deauville score 1-2, 3, and 4-5. With a median follow-up of 54.7 months (IQR, 30.2-84.5), 5-year PFS rate was 35.7% (95% CI, 30.0-41.4) and OS rate was 47.1% (95% CI, 40.8-53.4). NCCN-IPI risk and post-treatment PET-CT scan were independently associated with PFS in the multivariate analysis (for LI NCCN-IPI, hazard ratio [HR] 1.615, 95% CI 0.838-3.113; HI NCCN-IPI, HR 3.063, 95% CI 1.626-5.769; high NCCN-IPI 4.475, 95% CI 2.231-8.977; *P*<0.001: for post-treatment Deauville score 3, HR 1.895, 95% CI 1.281-2.801; score 4-5, HR 6.916, 95% CI 4.948-9.667; *P*<0.001). We stratified patients into 5 groups based on risk of progression: a low (low NCCN-IPI and Deauville score 1-2), INT-1 (low NCCN-IPI and Deauville score 3, or LI NCCN-IPI and Deauville score 1-2), INT-2 (HI NCCN-IPI and Deauville score 1-2), high (high NCCN-IPI and Deauville score 1-2, or LI to high NCCN-IPI and Deauville score 3), and very high (Deauville score 4-5). The risk model showed a strong association with PFS and OS (Figure 1).

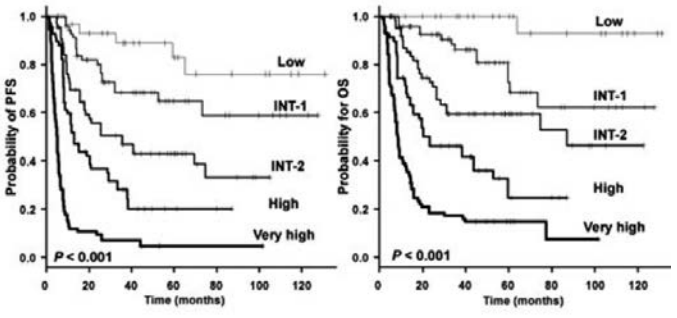

Figure 1.

Summary/Conclusions: This study proposes a new risk stratification model incorporating baseline NCCN-IPI in combination with post-treatment Deauville score on PET-CT scan in patients with newly diagnosed nodal PTCL.

P570

LONG-TERM EFFICACY AND SAFETY OF CRIZOTINIB IN RELAPSED ALK POSITIVE LYMPHOMA PATIENTS: CLINICAL AND BIOLOGICAL CORRELATES

F. Farina[1,2,3,*], M. Ceccon[1], S. Mori[2], L. Verga[2], L. M. Borin[2], L. Mologni[1], D. Fontana[1], G. Geeta[1], R. Piazza[1], C. Gambacorti-Passerini[1,2]
[1]School of medicine, Milano Bicocca University, [2]Haematology Department and Clinical Research Unit, San Gerardo Hospital, Monza, [3]Haematology and Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Milano, Italy

Background: Anaplastic large cell lymphoma (ALCL) is an aggressive disease with over 60% ALK-tyrosine kinase (TK) receptor positivity due to oncogenic fusions proteins containing ALK, mainly NPM-ALK. Crizotinib, an ALK inhibitor, proved to be effective in ALK positive tumors and in particular in ALK+ ALCL, with Objective Response Rates (ORR) in the 80-90% range. Long-term data on the safety and efficacy of crizotinib are lacking.
Aims: In this work, we analysed long-term clinical outcomes in 16 patients treated with crizotinib for ALK positive ALCL and we evaluated the presence of TK domain-point mutations in patients who relapsed during crizotinib treatment.
Methods: 16 patients were treated at the Clinical Research Unit, S. Gerardo Hospital, Monza (Italy) from June 2010 to December 2015 with a median follow up of 7.3 months (range 2.4-72 months). Survival curves were obtained using GraphPad Prism 5; differences were evaluated with Mantel-Cox test and Gehan-Breslow-Wilcoxon test. In 4/7 relapsed patients the TK domain of ALK were amplified from peripheral blood samples obtained at the time of crizotinib-relapse and subjected to deep sequencing. Subsequently we profiled *in-vitro* the activity of 2nd/3rd generation ALK inhibitors (brigatinib, alectinib, ceritinib and lorlatinib) with a murine BaF3 cell model and obtained their level of sensitivity/resistance to the drugs.

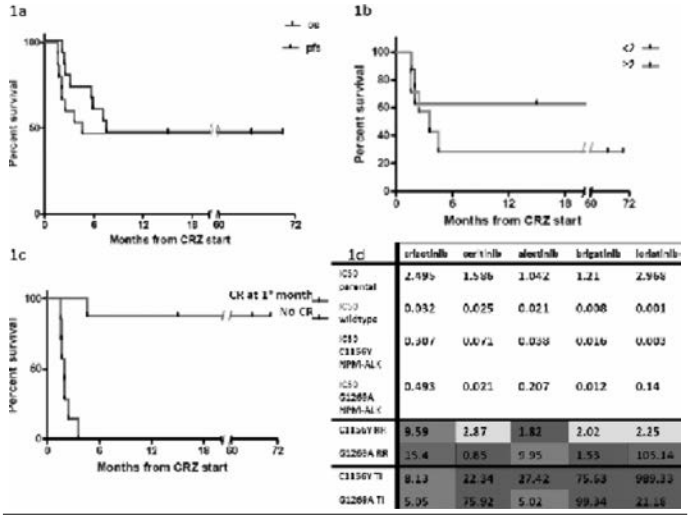

Figure 1.

Results: Median age at diagnosis was 25.5 years (range 16-38 years) and 8/16 patients were male. Median previous line-therapies were 2.5 (range 1-5). In the Intention-To-Treat population which includes 1 patients who died after the first crizotinib dose, 13/16 patients (81.25%, 95% CI 53-95%) and 8/16 patients (50%, 95% CI 25-75%,) achieved an OR and a complete response (CR) after 1 month of therapy, respectively. Median overall survival and progression free survival (PFS) were 7.53 months and 4.57 months respectively (fig 1a). Median time to progression was 50 days (range 47-137 days). OS and PFS at 1 and 3 years from treatment were 44%. At the last follow up 7 patients were still on treatment and in CR (median treatment duration 44 months [range 15-72 months]). There was a significant difference in 3 years PFS between patients in whom CR was obtained after 4 weeks of crizotinib and those who didn't (PFS at 3 years 87.5% *vs* 0%, p<0.001-fig 1c); patients with less than 2 previous lines of therapy showed a borderline better 3 years PFS (66% *vs* 33%, p=0.08-fig 1b). Crizotinib was well tolerated and there were no cumulative adverse events (AEs) over this long-term follow-up. The only G3 AEs reported were transient neutropenia and creatine-kinase elevation. The deep sequencing of 4 NPM-ALK in relapsed patients demonstrated the presence in 2/4 samples of ALK mutations G1269A and C1156Y, which were not present in samples before crizotinib treatment. The level of *in vitro* resistance of these mutations showed a high level of resistance to crizotinib (resistance index for C1156Y and G1269A: 9.59-15.4 respectively). The sensitivity *in vitro* of these mutations to ALK-inhibitors was also evaluated: all inhibitors, except alectinib for G1269A, were active with a therapeutic index (TI) >20 (fig 1d). TI values, as previously reported by Mologni L. et al (Oncotarget. 2015 Mar 20;6(8):5720-34), provide a view of the therapeutic impact of a mutation: the bigger the value, the more targetable is the mutation with the inhibitor.

Summary/Conclusions: Crizotinib confirmed to be an effective and safe therapy for advanced relapsed ALK+ ALCL, with durable responses up to 6 years after treatment initiation and no relapse later than 4 months. These results represent the longest available safety record for crizotinib. ALK point mutations can develop and 2nd/3rd generation inhibitors may be a therapeutic opportunity for patients who develop resistance to crizotinib.

P571

PRELIMINARY RESULTS FROM AN OPEN-LABEL, PHASE II STUDY OF TIPIFARNIB IN RELAPSED OR REFRACTORY PERIPHERAL T-CELL LYMPHOMA

T. Witzig[1], L. Sokol[2], E. Jacobsen[3], R. Advani[4], R. Mondejar[5], M. Piris[6], F. Burrows[7], C. Melvin[7], V. Mishra[7], C. Scholz[7,*], A. Gualberto[7]
[1]Mayo Clinic, Rochester, [2]H. Lee Moffitt Cancer Center & Research Institute, Tampa, [3]Dana Farber Cancer Institute, Boston, [4]Stanford University Medical Center, Stanford, United States, [5]IDIVAL Instituto de Investigación Marqués de Valdecilla, Santander, [6]Fundación Jiménez Díaz, Madrid, Spain, [7]Kura Oncology, La Jolla, United States

Background: Tipifarnib is a potent and selective inhibitor of farnesyltransferase (FT). FT catalyzes post-translational attachment of farnesyl groups required for localization of signaling molecules to the inner cell membrane. CXCL12 is a chemokine that is essential for hematopoietic stem cell (HSC) homing to the bone marrow and lymphoid organs and for maintenance of HSCs and immune cell progenitors. CXCL12 is known to signal in part through HRAS, a signaling protein that is uniquely farnesylated. Tipifarnib has previously been shown to be well tolerated and to have a 41% response rate (7 responses out of 17 patients) in patients (pts) with T-cell Non-Hodgkin Lymphoma, including 4 objective responses in 8 pts with peripheral T-cell lymphoma (PTCL) (Witzig et al, 2011). Building on this prior experience, we report herein the preliminary efficacy, safety and biomarker data from our ongoing Phase 2 study in PTCL.
Aims: This Phase 2 study is a multi-institutional, single-arm, open-label, two-stage (11+7) study designed to determine the efficacy and safety of tipifarnib in pts with relapsed/refractory (R/R) PTCL.
Methods: Pts with R/R PTCL after prior cytotoxic systemic therapy, aged ≥ 18 years old, and with a performance status of 0-2 were eligible. Informed consent was obtained. The following subtypes of PTCL were eligible for enrollment: PTCL, not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associated T-cell lymphoma (EATL), extranodal natural killer (NK) T-cell lymphoma, nasal type and subcutaneous panniculitis-like T-cell lymphoma. The primary endpoint of the study is overall response rate. Secondary endpoints include safety and tolerability, duration of response (DOR) and progression free survival (PFS). Based on activity observed in the first 18 pts in the study, the protocol has been amended and enrollment is ongoing to an expansion cohort in AITL (N=12). Enrolled pts are treated with tipifarnib 600mg administered orally twice daily on days 1-7 and 15-21 of 28-day treatment cycles until progression of disease or unacceptable toxicity. Biomarker studies included gene expression profiling of pretreatment tumor biopsies by RNASeq and DNA next-generation sequencing (NGS). Clinical trial information: NCT02464228.

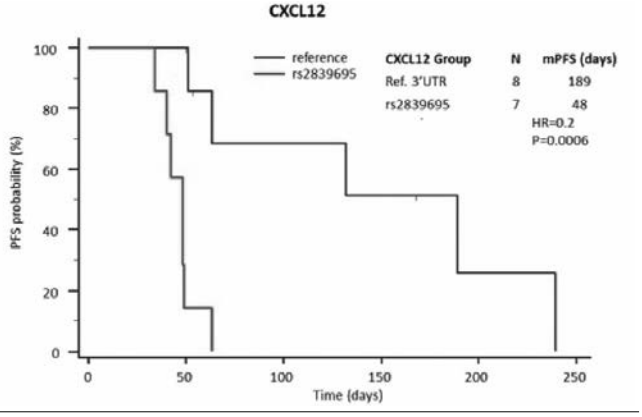

Figure 1.

Results: At data cut-off (2/15/2017), 18 pts (2 AITL, 1 ALK- ALCL, 15 PTCL-NOS) were treated with tipifarnib. Most common treatment-related AEs (grade ≥ 3) were myelosuppression, including neutropenia (61%), anemia (39%) and thrombocytopenia (39%). 3 pts achieved a partial response (2 AITL; 1 PTCL-NOS) and 3 additional pts experienced stable disease >6 months. Tumor DNA from 16 pts was sequenced using NGS. A high rate of CXCL12 3'UTR single nucleotide variation (SNV) was observed. Seven of 16 pts carried the rs2839695 variant while an additional patient carried a novel variant. The presence of 3'UTR SNVs was associated with low levels of CXCL12 gene expression and disease progression (Figure) while all pts deriving clinical benefit from tipifarnib carried reference (wild type) 3'UTR CXCL12 and had tumors that expressed high levels of mRNA for this chemokine. Testing of circulating CXCL12 levels is ongoing.
Summary/Conclusions: Although this study is ongoing, these preliminary data indicate that tipifarnib is generally well-tolerated and has antitumor activity, particularly in pts with AITL histology, absence of 3'UTR CXCL12 SNV and high levels of CXCL12 gene expression.

Background: High-dose chemotherapy before autologous stem cell transplantation (ASCT) is a therapeutic option as a consolidation in primary or relapsed lymphoma. BEAM conditioning is generally used. Alternative conditioning regimens have been published but few data are available.
Aims: To evaluate tolerance and efficacy of the BAM (Busulfan, Aracytin and Melphalan) conditioning before ASCT.
Methods: We conducted a retrospective study in 188 French patients treated between 2000 and 2015. Data were retrospectively collected from the Promise database. Informed consent was obtained from all patients.
Results: Indications for ASCT were diffuse large B-cell lymphoma (n=54, 29%), mantle-cell lymphoma (n=42, 22%), Hodgkin's disease (n=33, 18%), low-grade non-hodgkin lymphoma (n=26, 14%), T-cell lymphoma (n=17; 9%), Burkitt's lymphoma (n=8, 4%) and B-cell lymphoma (n=8, 4%). Median age at diagnosis was 50.9 years (35.7-59.9). Time between diagnosis and ASCT was 295 days (176-777). Patients received 1 (n=82, 44%), 2 (n=83, 44%), 3 or more (n=18, 10%), unknown (ND) (n=5, 2%) treatment lines before ASCT. Among the 138 B-cell lymphoma patients, 132 received rituximab before ASCT. Only 20 patients received prior radiotherapy. In all patients, ASCT was the first transplantation. In 11 patients, ASCT was planned as part of a multiple graft protocol. At the time of transplantation, 116 (62%) patients were in complete remission, 54 (29%) in partial remission, 13 (7%) in relapse or progression, and 5 (2%) ND. ASCT was documented in 186 (99%) patients. Median time to neutrophil and platelet (>50 Gigal/L without transfusion) recovery was respectively 11 days [10-12] and 19 days [14-32]. Infectious complications were found in 153 patients. One hundred (53%) patients had undocumented fever, 19 (10%) had sepsis, 150 (80%) had grade 1-4 mucositis during neutropenia with a WHO toxicity grading of 2 (42%), 3 (39%) and 4 (19%). Colitis with a median duration of 7 days [5-10], was reported in 73 patients, with a maximum toxicity grading of 1-2 (n=43, 59%), 3 (n=21, 29%) or 4 (n=4, 6%) and ND in 5 patients. Only 2 (1%) patients had non-fatal hepatic sinusoidal obstruction syndrome. Pulmonary toxicity was reported in 33 (17.6%) patients with 8 cases of respiratory distress syndrome. Respiratory distress was fatal in one patient but occurred more than 6 months after ASCT and salvage treatment. Seven (3.7%) patients reported secondary cancers (all were solid tumors except one acute leukemia). Median follow-up was 17.1 months [11.3-29.5]. At the time of the study, 47 (25%) patients had relapsed. Cumulative incidence of relapse was 6.24% at 3 months and 17.31% at 12 months. At the end of the follow-up, 149 (79%) patients were alive. The main causes of death were relapse (n=15, 41%) and toxicity (n=16, 43%). Median overall survival (OS) was not reached and progression-free survival was 71.5 months [47-NR]. Relapse-free mortality was 1.66% at 3 months and 4% at 12 months. In the univariate analysis, the number of treatment lines (1 or 2) before ASCT and previous use of monoclonal antibodies positively impacted the OS. Conversely, the multiple graft protocol had an unfavorable impact on OS.
Summary/Conclusions: BAM conditioning before ASCT for lymphoma helps to control disease activity without excessive toxicity. It may be a suitable alternative to BEAM in case of drug shortage. However, comparative studies are needed to confirm these findings.

Bone marrow failure syndromes incl. PNH - Clinical

ANALYSIS OF MICRORNAOME, PROTEOME AND METABOLOME OF EXOSOMES FROM PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

R. Teruel-Montoya[1,2], G. Luengo-Gil[2], F. Vallejo[3], J. E. Yuste[3], N. Bohdan[2], S. Espín[2], N. García-Barberá[2], C. Martínez[2], J.C. Espín[3], V. Vicente[1,2], I. Martínez[1,2,*]
[1]Grupo de Investigación CB15/00055, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Madrid, [2]Servicio de Hematología y Oncología Médica, Hospital Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, [3]Research Group on Quality, Safety and Bioactivity of Plant Foods, CEBAS-CSIC. 30100, Campus de Espinardo, Murcia, Spain

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a clonal disease caused by the lack of glycosyl inositol phosphatidyl anchored proteins at the cell membranethat leads to intravascular hemolysis upon complement activation. Patients have intravascular haemolysis with high risk of thrombosis, and a variable degree of bone marrow failure. Treatment with Eculizumab reduces intravascular hemolysis and also the thrombotic risk. The mechanism of thrombosis in PNH is still unknown. Exosomes are extracellular vesicles released by cells and whose secretion is closely related with the inflammatory status. Exosomes participate in cell communication by activating signaling pathways and transferring genetic material, *i.e.* miRNA, and proteins to host cells.
Aims: To describe the microRNAome, proteome and metabolome of exosomes from PNH patients to identify potential biomarkers of the disease and to investigate its relationship with the mechanism of thrombosis in these patients.
Methods: Plasma exosomes were isolated from 5 healthy controls and from 9 PNH patients(6 with Eculizumab, 3 with thrombosis –ET- and 3 without thrombosis –ENT-, and 3 without Eculizumab) using Total ExosomeIsolation kit (ThermoFisher).MiRNAsfrom exosomeswere purified using Nucleo Spin miRNA Plasma Kit (Macherey-Nagel).miRNA expression was evaluated by plasma/serum focus miRNAs PCR panel V4 (Exiqon). Proteomic analysis of exosomes was performed at the OMICs core facilities. Untargetted metabolomic analysis was performed by using combination of gas chromatography and liquid chromatography (LC) with mass spectrometry (MS). Additionally; latest advances were used combining LC-MS-solid phase extraction-nuclear magnetic resonance (UPLC-QTOF_SPE_NMR) 'on line' for unequivoque structural elucidation of unknown metabolites.
Results: Mir-16-5p and miR-451a had lower levels in patients *vs* controls. Eculizumab treatment increased their expression, particularly in the group with thrombosis. Eculizumab also decreased miR-223-3p (the most abundant miRNA in platelets and that has been associated with its reactivity)and increasedmiR-15a-5p levels (0.50- and 3.12-fold respectively). Those proteins differentially expressed in patients and controls were related with the complement system and the immune response. We identified an increase in the plasma hemoglobin levels in patients *vs* controls (4.9-fold), which is related with platelet activation. It is also noteworthy the decrease (1.5-fold) of the anticoagulant Protein S in patients *vs* controls. When the analysis was performed among the 3 groups of patients, only Ig heavy chain V-I region HG3 increased in 3.9-fold in the Eculizumab group *vs* without Eculizumab group, which could be related with the treatment. We identified quite few metabolites inside the exosomes, all of them associated with cell toxicity or immune response. The levels of Cholesterol, HydroxyTerbinafine-glucuronide and Diacyl-glycerol decreased in 17.3, 17.6 and 19.4-fold, respectively in patients treated with Eculizumab. Interestingly, the Aminoethylphosphonicacid, Cholesterol and PGF2 increased 16.7-; 21- and 19.4-fold in patients with thrombosis.
Summary/Conclusions: Our study supports that exosomes contain material that may influence the pathological status of the PNH patients. In concordance, most of the proteins, miRNAs and metabolites are related with the complement system or the inflammatory response. In future experiments, some of the proteins, miRNAs and metabolites should be validated to define whether they could be considered biomarkers.

SEVERE CHRONIC NEUTROPENIA: THE ROLE OF PRIMARY IMMUNODEFICIENCY AS CAUSATIVE AGENTS. A SINGLE CENTER DATA

F. Fioredda[1,*], F. Pierri[1], C. Micalizzi[1], M. Calvillo[1], E. Palmisani[1], I. Ceccherini[2], A. Grossi[2], M. Lanciotti[1], P. Terranova[1], T. Lanza[1], M. Miano[1], C. Dufour[1]
[1]Haematology Unit, [2]Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

Background: Severe Chronic Neutropenia may be a primary disease, usually defined as congenital (CN), or a condition mainly secondary to autoimmune disturbances (SN) (1,2). CN rises in early infancy, has a marrow block at pro/myelocyte, classically carries genes ELANE/HAX1 mutations in 70% of cases and is G-CSF dependent. SN is accompanied by extrahaematological signs and/or positivity of autoimmune markers; bone marrow has a normal morphology or is "left shifted". In spite of these categorization many cases do not fit either group and share features of both of them. These "Ovelap Neutropenia" (ON) patients are a diagnostic and management challenge.
Aims: Investigate the genetic backgroud of this ON from a cohort of chronic neutropenia subjects screened at Hematology Unit of Gaslini Hospital and characterize their clinical phenotype.
Methods: Patients with severe chronic neutropenia were seen prospectively in our center and diagnosed/followed-up according to published guidelines(3,4). Genetic diagnosis includes classical Sanger technique foe commonest severe chronic neutropenia genes and an enlarged NGS panel including also those gene responsible for PID.
Results: From 2008 to 2016, 24 patients (13 males) with median age at last follow of 18yrs (range 28 mo-51y) had a complete work up for severe chronic neutropenia (Table 1). Ten/24 subjects (43%) were diagnosed as classical CN with ELANE mutation found in the majority (80%) of cases. Seven/24 (29%) were diagnosed as SN and the remaining 7/24 (29%)as ON.A PID genes mutation was found in a total of 8/24 patients (30) with 5 patients belonging to 7 SN subjects (71%) and 3 to the 7 ON subjects (42%).Table 1 shows clinical hematological characteristic of the 3 categories of patients.
Summary/Conclusions: A considerable portion (30%) of subjects affected with severe chronic neutropenia have been identified as PID. In the group of ON subjects a mutated PID gene was found in 3/7patients and muations of ELANEin 2/7 patients. No mutation was found in the remaining 2.The phenotype of ON subjects is characterized by extra-hematological autoimmune symptoms, by maturation block and by the frequent involvement of more than one hematopoietic lineage. This phenotype my suggest to access to an enlarged genetic panel including PID genes for genetic diagnosis. An accurate immunological and genetic work may support diagnosis and management of these difficult patients.

Table 1.

TREATMENT WITH HORSE-DERIVED ANTI-THYMOCYTE GLOBULIN LEADS TO ENDURING HEMATOLOGICAL RESPONSES AND A 1.5-YEAR SURVIVAL PROBABILITY OF 87% IN ADULT ACQUIRED APLASTIC ANEMIA PATIENTS IN THE NETHERLANDS

J. Tjon[1], L. de Wreede[2], F. Falkenburg[1], M. de Groot[3], H. Koene[4],

S. Langemeijer[5], E. Meijer[6], M. Raaijmakers[7], R. Raymakers[8], T. Snijders[9], S. Zeerleder[10], S. Halkes[1,*]
[1]Hematology, [2]Medical Statistics, LUMC, Leiden, [3]Hematology, UMCG, Groningen, [4]Hematology, Antonius Ziekenhuis, Nieuwegein, [5]Hematology, Radboud MC, Nijmegen, [6]Hematology, VUMC, Amsterdam, [7]Hematology, Erasmus MC, Rotterdam, [8]Hematology, UMCU, Utrecht, [9]Hematology, MST, Enschede, [10]Hematology, AMC, Amsterdam, Netherlands

Background: Acquired aplastic anemia (AA) is a rare disease characterized by bone marrow failure. First-line treatment is either an allogeneic stem cell transplantation (alloSCT) or intensive immunosuppressive therapy (IST) consisting of Anti-Thymocyte globulin (ATG) and ciclosporin. Based on studies from the National Institute of Health, the Dutch guidelines for diagnosis and treatment of aplastic anemia recommend horse-derived ATG (ATGAM) as the preferred type of ATG. Patients who are refractory after first-line treatment with IST can be treated with second-line alloSCT or rabbit-derived ATG (Thymoglobulin). Eltrombopag, a Thrombopoietin-mimetic, is registered for second-line treatment of AA since May 2016. In order to evaluate the guidelines, a national registry was started in 2014 in which seven university hospitals and two large non-academic hospitals collect data on all consecutive adult aplastic anemia patients, including those that received ATGAM and ciclosporin as first-line treatment.
Aims: To evaluate the safety and efficacy of first line treatment using ATGAM and ciclosporin in adult patients with acquired aplastic anemia in the Netherlands.
Methods: Data on adults with acquired aplastic anemia who received ATGAM as first-line treatment was collected in the LUMC, AMC, UMCG, UMCU, VUMC, UMCN, Erasmus MC, Medisch spectrum Twente and Antonius Ziekenhuis Nieuwegein. The data included baseline-characteristics and follow-up data at 3, 6, 9 and 12 months. After 12 months, follow-up data was collected at least yearly. All patients received first-line treatment with ATGAM (40mg/kg for 4 days intravenously) and ciclosporin. Response was defined as complete in case of normalization of blood values and as partial in case of transfusion independency and neutrophil count >0.5 x 10^9/L. Overall survival was evaluated with the Kaplan-Meier method.
Results: In October 2016, 70 patients were registered in the NVvH registry. Median age at start of treatment was 53 years (18-79) and median follow-up time was 18 months. Overall survival probability after 18 months was 87%. Fifty-nine patients were evaluable for a response at 6 months after treatment. Response was seen in 36 patients (61% (CI 49-73%)). Patients with a response at 6 months, had an overall survival probability of 94% at 12 months thereafter. After initial response at 6 months, aplastic anemia relapsed in 4 patients and 1 patient developed AML. From the 23 non-responding patients, 7 patients continued ciclosporin after 6 months without additional treatment. Five of these 7 patients became transfusion independent up to 16 months after treatment with ATGAM. Sixteen of the patients without a hematological response 6 months after ATGAM received second-line treatment consisting of alloSCT (n=8), Thymoglobulin (n=4), Eltrombopag (n=3) or Danazol (n=1). From the 16 patients that received second-line treatment, 10 patients eventually had a hematological response. Patients without a response at 6 months, had an overall survival probability 12 months thereafter of 84%. One patient developed secondary AML after second-line treatment with Thymoglobulin.
Summary/Conclusions: Six months after treatment with first-line ATGAM, 61% of the adult patients with acquired aplastic anemia is transfusion independent. Half of the remaining patients becomes transfusion independent after rescue treatment or after continuation of ciclosporin beyond 6 months.

IMMUNE RECONSTITUTION IN PATIENTS WITH ACQUIRED SEVERE APLASTIC ANEMIA AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION

X. Pei[1,*], Y. Chang[1], X. Huang[1], X. Zhao[1]
[1]Peking University People's Hospital & Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Acquired severe aplastic anemia (SAA) is a rare disease that is characterized by bone marrow failure that results in pancytopenia and hypoplastic bone marrow. Hematopoietic stem cell transplantation (SCT) is one of the main treatment strategies for SAA. In recent years, for patients who require transplantation, but have no human leukocyte antigen (HLA) matched donors, haploidentical SCT (haplo-SCT) is an important alternative option. Delayed immune reconstitution (IR) after haplo-SCT played a crucial role in infections and graft-versus-host disease (GVHD) and was considered a barrier to the wider application of haplo-SCT in SAA. The assessment of immune reconstitution may provide tools to better predict and modulate adverse outcomes and subsequently improve survival after transplantation. However, the kinetics of immune recovery in patients with SAA after haplo-SCT have not been studied systematically.
Aims: We aim to provide the kinetics for immune reconstitution in SAA patients who receive haplo-SCT, investigate the factors that may affect immune recovery and assess the impact of immune cell subset recovery on transplant outcomes.
Methods: In this study, we examined immune cell subset counts and immunoglobulins in 81 SAA patients from day 30 to day 365 after haplo-SCT. The immune cells analyzed in this study including lymphocyte, monocyte, $CD3^+$ T cell, $CD8^+$ T cell, $CD4^+$ T cell, $CD4^-CD8^-$ T cell, $CD8^+CDC28^+$Tcell, $CD4^+CD28^+$Tcell, $CD4^+$ memory T cell and $CD4^+$ naïve T cells. Simultaneously, we determined which factors influence immune reconstitution and analyzed the effects of immune cell subsects on transplant outcomes.
Results: (i) The reconstitution of different immune cell subsets occurred at different rates after haplo-SCT. Monocytes were the first to recover, followed by $CD8^+$ T and $CD19^+$ B cells, and finally $CD4^+$ T cells. Early $CD4^+$ T cell recovery occurred at the expense of memory cells, whereas naïve $CD4^+$T cells rose only 9 months after SCT. (ii) In the multivariate analysis, lower recipient age, female gender, high mononuclear cell counts and $CD4^+$ T cell counts in the graft were associated with improved immune recovery after transplant. (iii) A CD4/CD8 ratio less than 0.567 on day 30 post-transplantation was associated with lower treatment related mortality and higher overall survival after haplo-SCT in SAA patients.
Summary/Conclusions: We provided the kinetics for immune recovery in SAA patients who received haplo-SCT. In general, our study demonstrated that the recovery of monocyte and CD8+ T cells was fast in SAA patients, whereas the recovery of the $CD4^+$ T cell subset was delayed. In addition, our data suggested that the CD4/CD8 ratio may be useful for predicting transplant outcomes in SAA patients after they complete haplo-SCT. Our results may be useful for making better predictions and modulating the IR of SAA patients, which would subsequently improve the outcomes after transplantation.

DEVELOPMENT OF A SCREENING AND DIAGNOSTIC ALGORITHM FOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA USING A MODIFIED DELPHI PANEL METHODOLOGY

A. Röth[1,*], J. Maciejewski[2], J.-I. Nishimura[3], D. Jain[4], J. Weitz[5]
[1]University Hospital Essen, Essen, Germany, [2]Cleveland Clinic, Cleveland, United States, [3]Osaka University Graduate School of Medicine, Osaka, Japan, [4]Alexion Pharmaceuticals, Inc., Cambridge, United States, [5]McMaster University, Hamilton, Canada

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare clonal hematopoietic stem cell disorder that manifests with hemolytic anemia due to uncontrolled complement activation, bone marrow failure, and thrombosis. Diagnosis is essential because PNH is a progressive disorder associated with substantial morbidity and mortality. The protean clinical manifestations of PNH complicate diagnosis, and subsequently the diagnosis is often delayed or missed. Although national diagnostic guidelines are available, international expert consensus on PNH screening and diagnosis is lacking.
Aims: An international panel of PNH experts was assembled to develop a clinically relevant, consensus-driven screening and diagnostic algorithm for PNH.

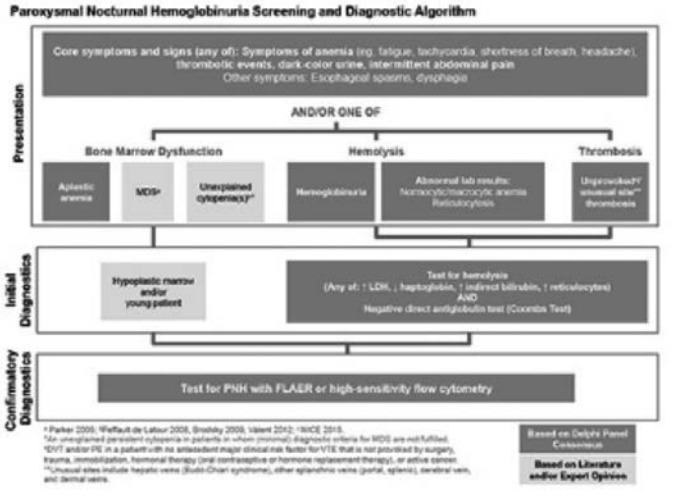

Figure 1.

Methods: An expert advisory committee of 4 PNH experts from North America, Europe, and Japan was assembled. Using a modified Delphi methodology, consensus was gained on the symptoms and signs of PNH and the laboratory tests required for screening and confirmation of diagnosis. Globally representative Delphi panelists were identified through a double-blinded screening process and asked to complete 2 rounds of web-based questionnaires. The questionnaires were developed by the expert advisory committee and presented to the Delphi panel in a case-based format. In the first round, Delphi panelists were given 5 blinded case studies—each including details on clinical presen-

tation and past medical history—and were asked to provide their differential diagnosis and the tests they would order to establish the diagnosis in free-text format. To reduce bias, Delphi panelists were blinded to the fact that the study was focused on PNH. Responses mentioned by ≥50% of Delphi panelists in the first round were included in the second-round questionnaire. For each case in the second-round questionnaire, Delphi panelists were presented with a series of consensus statements regarding potential diagnoses and the need for specific tests/data from a multiple-choice list and asked to respond with their level of agreement on a 4-point Likert scale. Consensus in the second round was attained if ≥80% of Delphi panelists agreed on a given screening or diagnostic approach.
Results: Twelve Delphi panelists from 6 countries, all of whom were clinicians with expertise in PNH, were recruited. Consensus was reached on 22 of 23 PNH screening and diagnostic decision points identified by the Delphi panelists. Specifically, consensus was gained on the core symptoms and signs of PNH at presentation, including hemolysis, bone marrow dysfunction, and thrombosis. Consensus was also reached for 36 of 38 specific screening and diagnostic tests required at each decision point to narrow the differential diagnosis and to confirm the diagnosis of PNH. The level of agreement on screening and diagnostic decision points and tests was sufficient to enable the development of a screening and diagnostic algorithm (Figure) that is consistent with the published literature and with the real-world experience of the international expert advisory committee.
Summary/Conclusions: The modified Delphi methodology facilitated development of a consensus-based, clinically relevant PNH screening and diagnostic algorithm. This algorithm provides clinicians with varying levels of expertise detailed guidance on how to screen for and diagnose PNH.

DIAMOND-BLACKFAN ANEMIA IN THE NETHERLANDS: AN OVERVIEW OF CLINICAL CHARACTERISTICS AND UNDERLYING MOLECULAR DEFECTS

B. Van Dooijeweert[1,*], M. Bierings[2], A. MacInnes[3], M. Bartels[4]
[1]Pediatric Haematology, clinical research, [2]Pediatric Haematology and Stem Cell Transplantation, Wilhemina Children's Hospital, Utrecht, [3]Euro DBA, genetic metabolic diseases, AMC, Amsterdam, [4]Pediatric Haematology and Oncology, Wilhelmina Children's Hospital, Utrecht, Netherlands

Background: Diamond-Blackfan anemia (DBA) is a rare genetic disorder, characterized by bone marrow failure (anemia), congenital anomalies and a predisposition for malignancies. DBA is characterized by a highly heterogeneous nature, both clinically and genetically. Most of our understanding of this disorder stems from molecular studies combined with extensive data-input from international patient registries.
Aims: The aim of our retrospective study was to create an overview of the pediatric DBA population in the Netherlands.
Methods: Forty-four patients (age 0-18yr) diagnosed with DBA from all Dutch pediatric hospitals were included in this study and their clinical and genetic characteristics were collected from patient records.
Results: Congenital malformations were present in 19/41 patients (46,3%), varying from craniofacial and cardiac defects to urogenital and developmental disorders. An underlying genetic defect was identified in 23 patients (56,1%), the majority of which were found in the RPS19 gene (n=10; 45%). No significant diversities in malformations, course of disease or response to treatment were observed when comparing patients with or without identified genetic defects. In agreement with previous reports, two patients harboring defects in RPL11 displayed a more severe phenotype, including craniofacial malformations, thumb abnormalities, and cardiac defects. In contrast, our patient with a mutation in RPL5 has no associated congenital abnormalities, while previous studies reported a very high frequency (83%) of associated congenital defects. Furthermore we observed a relatively high number (12/23) of novel mutations in well-known 'DBA-genes', defined as novel variants. In addition, we have identified a novel 'DBA-candidate', describing a genetic defect in RPL9, in a patient with multiple congenital abnormalities (craniofacial defects, cardiac defects, colitis) in addition to severe anemia. Thirty-four (34/44) patients were treated with glucocorticoids, of which in thirty-one (31/34) patients a complete response was observed (91,2%). However, in 29% discontinuation was prompted by high-dosage-dependence, side effects, a weaning response, or a combination of these factors. Five patients (12,2%) were successfully transplanted with hematopoietic stem cells from either matched sibling donors (n=3) or matched unrelated donors (n=2), including two cases after the age of 10 years. Eleven patients (26,8%) were treatment-independent, defined as acceptable hemoglobin values without any therapy. No malignancies were thus far reported.
Summary/Conclusions: In line with previous reports, the Dutch pediatric DBA population is both clinically and genetically heterogeneous, with *RPS19* being the most frequently mutated gene. Interestingly, the majority of mutations in our cohort have not been described before, probably further underlining clinical heterogeneity. In addition, we have identified a novel DBA-candidate gene (*RPL9*), associated with a more severe phenotype, based on multiple associated congenital defects. While we created a comprehensive overview of the Dutch pediatric DBA population, limitations of our study include a relatively small number of patients, and the lack of complete genetic analysis (for all DBA candidate genes) in a relevant number of patients. Overall, to increase our understanding of genotype-phenotype correlation in DBA, and underlying pathophysiological mechanisms more generally, it crucial to further extend our genetic, and functional analysis of DBA-candidate genes, as well as compare, and share data from international registries.

NEXT GENERATION SEQUENCING IN BONE MARROW FAILURE SYNDROMES

E. Galvez[1,*], E. Sebastian[1], L. Madero[1], A. Catalá[2], C. Belendez[3], C. Diaz de Heredia[2], A. Galera[4], D. Plaza[3], I. Badell[2], E. Vallespin[5], P. Lapunzina[5], R. Perona[5], J. Surralles[6], J. Bueren[5], J. Sevilla[1]
[1]Hospital Infantil Niño Jesus, Madrid, [2]Grupo fallos medulares SEHOP, Barcelona, [3]Grupo fallos medulares SEHOP, Madrid, [4]Grupo fallos medulares SEHOP, Valencia, [5]CIBERER, Madrid, [6]CIBERER, Barcelona, Spain

Background: Inherited bone marrow failure syndromes (IBMFSs) are a heterogeneous group of genetic disorders, with similar clinical presentations, resulting in complex diagnosis. Molecular characterization is essential in order to establish diagnosis, treatment and prognosis. Next-generation sequencing (NGS) techniques seem to be a useful platform for genetically defining different IBMFSs.
Aims: To design a NGS panel with the objective of making a specific, fast and cost-effective diagnosis for these pathologies.
Methods: We developed a NGS panel of 164 genes involved in different IBMFSs. A total of 120 samples have been processed. Patients were classified into two groups based on the clinical presentation: classified IBMFS (CBMFS) for those with a clinical picture typical os some of these disorders, and unclassified IBMFS (UBMFS) for the others. For the NGS study the NextSeq platform of Illumina (Roche) has been used. Bioinformatic analysis has been oriented to the identification of point polymorphisms (SNPs) and insertions / deletions of small DNA fragments.
Results: Of the 120 samples processed, 10% (12/120) was not suitable for analysis. A total of 108 patients were studied. In 59,3% (64/108) causal mutations were detected. From the total samples analyzed (108), 75% (81/108) were included in the CBMFS patient group, obtaining a diagnostic yield of 64,2% (52/81). The remaining 27 patients (25%) were included in the UBMFS group and we found causal mutation in 37% (10/27). Therefore, it remains a percentage of patients without a genetic diagnosis, which seems more evident in the UBMFS group. This could be explained by the fact that the causal gene has not been described or due to the limitations of the technique.
Summary/Conclusions: NGS techniques are a fast and cost-effective option for the diagnosis of IBMFSs patients. In our series, we have reached a diagnosis rate of 59,3%, coinciding with that described in the literature. Undiagnosed patients should be included in new research projects.

P581

APLASTIC ANEMIA PATIENTS WITH MONOCYTE-DOMINANT PNH CLONES HAVE A UNIQUE PRESENTATION AND ARE LESS RESPONSIVE TO IMMUNOSUPPRESSIVE THERAPY

E. Nevill[1,*], D. Sanford[1], D. Forrest[1], D. Hogge[1], Y. Abou Mourad[1], R. Broady[1], M. Barnett[1], M. Power[1], C. Toze[1], K. Song[1], S. Nantel[1], S. Narayanan[1], A. Gerrie[1], H. Sutherland[1], B. Dalal[2], T. Nevill[1]
[1]Leukemia/BMT Program of BC, [2]Division of Hematopathology, Vancouver General Hospital, Vancouver, Canada

Background: Aplastic anemia (AA) is a bone marrow failure syndrome that can be successfully treated with either immunosuppressive therapy (IST) or allogeneic bone marrow transplantation (BMT). In ~50% of patients (pts) with AA, a clone deficient in glycosylphophatidyl inositol (GPI)-linked antigens–a paroxysmal nocturnal hemoglobinuria (PNH) clone–can be detected (Young, *Blood*, 2006). In recent years, highly sensitive techniques have been developed to test for PNH clones that have primarily focused on evaluating peripheral blood white cells. Neutrophils are routinely tested for expression of GPI with fluorescent aerolysin (FLAER); monocytes may also be analyzed but are not always evaluated in PNH testing. Our centre has previously reported that 60% of PNH positive tests show a higher monocyte clone than granulocyte clone and that there was >10% difference in 20% of these discrepant results (Razavi, *ISLH Proceedings*, 2015). Whether pts with discordant monocyte and granulocyte PNH clones have different clinical characteristics and/or response to IST has not been reported to date.
Aims: To compare the granuloyte and monocyte PNH clones in pts with AA to determine whether there are differences in clinical presentation and/or response to IST for pts with discordant clone sizes.
Methods: A retrospective review was performed on all patients >age 16 treated for AA with IST at VGH, the tertiary referral centre for the Province of BC, between 11/09 and 10/15. All patients had central pathology review and metaphase cytogenetic analysis that confirmed a diagnosis of AA. High-sensitivity flow cytometry testing with a sensitivity of 0.1% was done on all patients

to detect the presence of a PNH clone. Granulocytes, monocytes and erythrocytes were interrogated with multi-colour flow panels including CD59 and FLAER. The criteria for determining discordant granulocyte and monocyte clone sizes was dependant upon the absolute size of the smaller clone. For clones 0.1-10%, discordance was defined as when the larger clone was either ≥2 x the smaller clone or at least 1% (absolute value) greater. For smaller clones >10%, the larger clone had to be ≥110% its size. IST was uniform - Cyclosporine (CSA, 2.5mg/kg p.o. b.i.d.), anti-thymocyte globulin (ATG; ATGAM 40mg/kg IV daily x 4 days) and (Methylprednisolone 1mg/kg/day x 10 days). CSA doses were adjusted to maintain whole blood trough CSA level of 200-300 ug/L for 12-months followed by slow taper based upon hematologic response. Non-responders at 6 months were eligible to proceed to either a second cycle of ATG or BMT, if a suitable donor was available. Severity of AA [very severe (VSAA), severe (SAA) or non-severe (NSAA)] and response to IST [(none, partial (PR) or complete (CR)] were determined according to published criteria (Marsh, *Br J Haematol*, 2009). Statistical comparisons were done using a standard Chi square analysis.

Results: 30 pts with AA and a PNH clone were identified, 18 females and 12 males with median age of 50.5 years (range 17-71). There were 14 pts with NSAA, 13 with SAA and 3 with VSAA. Responses were seen in 20/30 pts (66.7%) including 13 PR and 7 CR. Six pts relapsed with CSA tapering and 5 responded to intensified IST; 2 pts required Eculizumab after evolving to a classic PNH phenotype. Six pts underwent BMT for primary non-response and 4 pts have died (2 post-BMT, 1 from complications of AA and 1 from breast Ca); 26 pts remain alive and well with a median follow-up of 48 mos (15-86). There were 17 pts (56%) with concordant granulocyte and monocyte clone sizes (Group 1), 4 pts (13%) had granulocyte-dominant disease (Group 2) and 9 pts (30%) had monocyte-dominant disease (Group 3). Group 3 pts were significantly more likely to have NSAA and showed a trend toward an inferior response rate to IST (Table 1).

Table 1.

	Group 1	Group 2	Group 3	p value
Median age (yrs)	52	40.5	41	NS
Severity of AA				
VSAA/SAA	10/17	4/4	2/9	
NSAA	7/17	0/4	7/9	**0.028**
Response rate (%)	12/17 (70.6)	4/4 (100)	4/9 (44.4)	**0.096**

Summary/Conclusions: Flow cytometry for a PNH clone is routinely done in AA although it may be important to evaluate both granulocyte and monocyte clone sizes. Pts with a larger monocyte than granulocyte clone size more frequently have NSAA and appear to have a lower response rate to IST. This may have therapeutic implications and could identify a population of pts requiring a unique therapeutic approach.

P582

RESPONSE TO ANTI-THYMOCYTE GLOBULIN (ATG) IN PATIENTS WITH APLASTIC ANEMIA (AA): A SINGLE-CENTRE EXPERIENCE OVER THE LAST 28 YEARS

M. Oelmüller[1,*], F. Alashkar[1], D. Herich-Terhürne[1], U. Dührsen[1], A. Röth[1]
[1]Department of Hematology, University Hospital Essen, Essen, Germany

Background: Aplastic anemia (AA) is a rare, usually acquired disorder characterized by bone marrow failure with bi- or pancytopenia and marrow hypoplasia. The classification into the three main subtypes is of prognostic and therapeutic relevance. Depending on disease severity, patient's age, and the availability of a potential HLA-identical donor, different therapeutic strategies are favored. Immunosuppressive therapy (IST) with anti-thymocyte globulin (ATG) and cyclosporin (CsA) is considered the initial standard treatment. A hematologic recovery is seen in up to 60-70% of the pts following horse-ATG (hATG) treatment, compared to 35-53% in rabbit-ATG (rATG) treated pts, considering hATG as first-line therapy in AA pts.

Aims: As response rates vary according to the different studies and the source of ATG being used, our aim was to retrospectively evaluate response rates in pts with AA receiving IST at the Department of Hematology at the University Hospital of Essen between 1988 until 2015.

Methods: In this single-center, retrospective analysis, approved by the institutional review board of the University Hospital of Essen, individual response rates to ATG, according to criteria reported by Camitta *et al.* 1975, were evaluated in 67 pts with AA (52% (35/67) females; median age 48 years (range 17-89 years)) being treated or monitored at the Department of Hematology between 1988 until 2015. 73% of the pts (49/67) were treated with hATG (ATGAM® (44/49) and Lymphoglobulin®). ATGAM® was administered at a dose of 40mg per kilogram (kg) body weight (BW) per day for 4 days and rATG (Thymoglobulin®) at a dose of 3.5mg/kg BW per day for 5 days, respectively. Pts in both arms simultaneously received CsA (5mg/kg BW) and prednisone (day 1-29).

Results: Following six months after primary ATG therapy, a hematologic recovery was seen in 66% of the pts (44/67). The hematologic response rate at 6 months was 75% (37/49) for hATG and 39% (7/18) for rATG (p=0.005). Irrespective the source of ATG we observed no significant difference in respect to gender (females: 71% (25/35) *vs* males: 59% (19/32)) or in the presence of a PNH clone (GPI-deficient granulocytes (FLAER) 67% (14/21) *vs* 79% (19/24) in pts with no detectable PNH clones), whereas in pts ≤50 years (yrs) a statistically higher rate in hematologic recovery was observed (≤50 yrs: 84% (31/37) *vs* >50 yrs: 43% (13/30); p<0.001). In primary refractory pts (34% (23/67)) (52% (12/23) in first-line treated hATG pts *vs* 48% (11/23) rATG treated pts) a second course with either hATG (3/9) or rATG (6/9) was initiated, achieving an overall hematologic recovery at 6 months in 3 pts (33% (1/3) hATG *vs* 33% (2/6) rATG treated pts). A disease relapse (median: 13 months after primary ATG therapy) was seen in 11 out of the 44 pts with primary hematologic recovery (25%) (82% (9/11) in first-line treated hATG pts *vs* two rATG treated pts). A salvage therapy with rATG was initiated in two pts, whereas in one other pt a second course with hATG was started. An overall response following relapse therapy was observed in 33% of the pts (1/3). Four refractory as well as relapsed pts were treated with eltrombopag respectively (final results are still awaited). A secondary HSCT (hematopoietic stem cell transplantation) was performed in 11 out of the 67 pts (16%), either being primary refractory or due to a disease relapse.

Summary/Conclusions: Our data are able to independently confirm the findings of previous studies concerning hematologic recovery rates in pts with acquired AA following IST with ATG by providing further evidence that rATG plus CsA is inferior to hATG plus CsA when administered as a first-line treatment. In addition, we were able to observe in pts ≤50 yrs, irrespective gender, an overall higher hematologic recovery. For this reason, it remains unclear why ATGAM® is still not approved in Germany as first-line therapy in pts with AA, as the only hATG product registered in Europe (Lymphoglobulin®) was withdrawn from the market in 2007.

Maria Misericordia, Udine, [5]Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, Italy, [6]Hematology, Institute of Oncology Research and Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, [7]Division of Hematology–Department of Translational Medicine, University of Eastern Piedmont, Novara, [8]Division of Hematology, S.Eugenio Hospital and University of Tor Vergata, Rome, Italy

Background: Stabilizing mutations of *NOTCH1* have been identified in about 10% of chronic lymphocytic leukemia (CLL) cases at diagnosis, with a higher frequency in unmutated *IGHV* (*IGHV*-UM), immuno-chemorefractory or advanced disease phase CLL, and have been associated with particularly unfavourable prognosis (Rossi et al, Blood, 2012; Del Poeta et al, Br J Haematol, 2013; Stilgenbauer et al, Blood, 2014). In CLL, all *NOTCH1* mutations disrupt the C-terminal PEST domain and cause an accumulation of an active NOTCH1 isoform, resulting in a sustained pathway activation.
Aims: To identify molecular/biological features of *NOTCH1* mutated CLL
Methods: The presence of *NOTCH1* mutations was investigated by NGS. Gene expression profile (GEP) was performed by a one-color labeling strategy using the 4x44K platform. Specific gene/protein validations were performed by QRT-PCR, western blotting, flow cytometry and immunofluorescence. CLL-like MEC-1 cell line was transfected with a vector containing a *NOTCH1* intracellular domain (NICD) or with a control vector. Cell proliferation was evaluated by CellTrace assay. Cell size was estimated by flow cytometry from Forward Scatter (FSC) values.

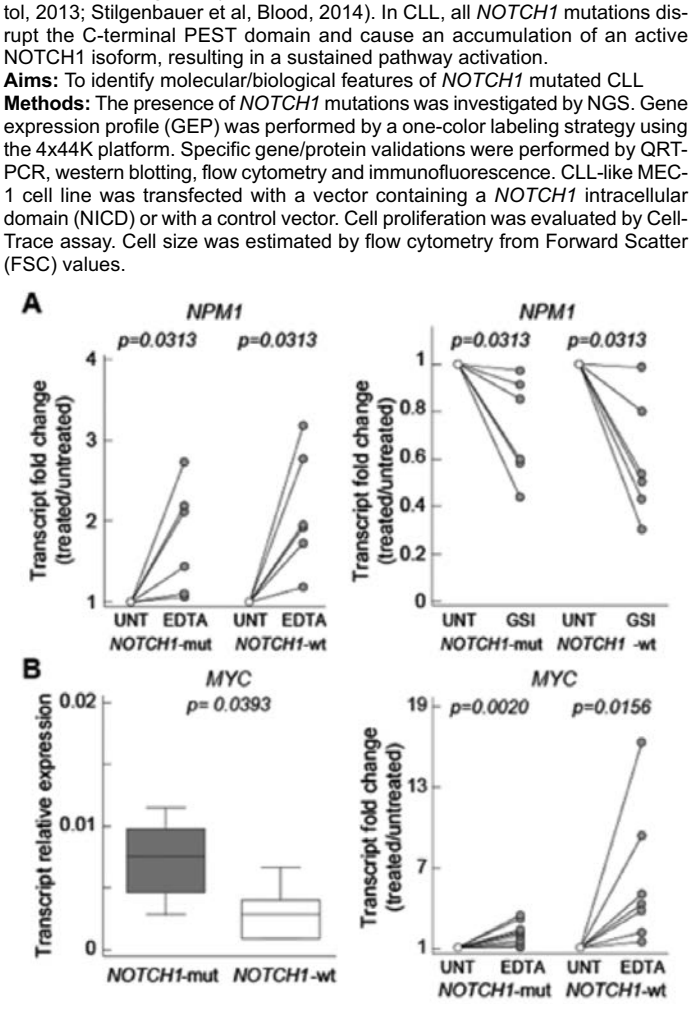

Figure 1.

Results: i) A GEP comparing purified cells of 10 *IGHV*-UM *CLL* cases (5 *NOTCH1*-mut; 15%>37% of *NOTCH1* mutated alleles) selected nucleophosmin-1 (*NPM1*) and genes codifying for several ribosomal proteins (*RNPs*) as significantly up regulated in *NOTCH1*-mut cases. A higher expression of *NPM1* and *RNPs* in *NOTCH1*-mut cases was validated in a wider independent series of 188 cases by QRT-PCR (76 *NOTCH1*-mut cases). In CLL, NPM1 expression was previously found higher in *IGHV*-UM cases (Rees-Unwin, Br J Haematol, 2009). In our series, no significant difference in *NPM1* transcript expression was found by comparing *IGHV*-UM and *IGHV*-M cases, but *NPM1* transcript expression was confirmed significantly higher in *NOTCH1*-mut than in *NOTCH1*-wt cases in the *IGHV* UM subgroup. **ii)** Western blotting in 11 CLL cases (5 *NOTCH1*-mut) confirmed a higher NPM1 protein expression in *NOTCH1*-mut cases, with a direct correlation with NOTCH1 expression (r=0.814). In *NOTCH1*-mut cases, the NPM1^{high}subpopulation, isolated by cell sorting, showed a higher *NOTCH1* mutational load than the NPM1^{low} subpopulation. **iii)** EDTA treatment of 12 CLL cases (6 *NOTCH1*-mut) activated NOTCH1 signaling (Rand et al, Mol Cell Biol, 2000), as from *HES1* and *DTX1* induction, and up-regulated *NPM1* and other *RNPs*. The same results were confirmed by co-culture of CLL cells with the JAGGED1-expressing M2-10B4 stromal cells. Inhibition of NOTCH1 signaling by gamma-secretase-inhibitor L-685,458 or by siRNA for *NOTCH1* reduced *NPM1* expression (Fig. A). **iv)** Previous studies identified *MYC* as a direct transcriptional target of NOTCH1 (Palomero et al, PNAS 2006) and, in turn, a transcriptional activator for both *NPM1* and *RNPs*. ChIP assays on MEC1-cells, transfected with exogenous NICD, revealed increased NICD binding to the *MYC* promoter, along with higher expression of *MYC*, *NPM1* and *RNPs*. Of note, after 48h culture, *NOTCH1*-mut CLL cases showed increased *MYC* transcript levels than *NOTCH1*-wt cases. *MYC* expression was further increased upon NOTCH1 activation by EDTA or by stromal cells co-cultures (Fig. B). *MYC* silencing by siRNA efficiently reduced *NPM1* transcript and protein expression. Moreover, CpG-ODN/IL-2 treatment, to induce MYC overexpression, also increased NPM1 transcript and protein levels in CLL cells. **iv)** *NPM1* silencing by siRNA was able to reduce proliferation rates and cell size of both NICD-transfected cells and control cells. In keeping with a *NOTCH1*-driven regulation of cell growth/ protein biosynthesis, activation of NOTCH1 signaling in 12 CLL cases (6 *NOTCH1*-mut) by EDTA or stromal cells co-culture, induced an increase in cell size.
Summary/Conclusions: *NOTCH1* mutations in CLL are associated with the overexpression of *MYC* and *MYC*-related genes involved in protein biosynthesis including *NPM1*, which are allegedly responsible for cell growth and/or proliferation advantages of *NOTCH1*-mut CLL.

CLL-LIKE B-CELL CLONES FROM MBLLO INDIVIDUALS PERSIST AT INCREASED COUNTS AFTER SEVEN YEARS OF FOLLOW-UP

I. Criado[1,*], A. Rodríguez-Caballero[1], L. Gutierrez[1], C.E. Pedreira[1], W.G. Nieto[1], C. Teodosio[1], V. Herraez[1], A. Romero-Furones[2], P. Fernández-Navarro[3], J. Almeida[1], A. Orfao[1]
[1]Department of Medicine, Center for Cancer Research, [2]Centro de Atención primaria de Salud Miguel Armijo, [3]Centro de Atención Primaria de Salud de Ledesma, Salamanca, Spain

Background: The presence of very low numbers of clonal B cells in peripheral blood (PB) of otherwise healthy individuals (low-count monoclonal B lymphocytosis -MBL^{lo}-) is a common finding in the general population. Since the vast majority of clonal B cells from MBL^{lo} subjects show a phenotype overlapping with CLL (chronic lymphocytic leukemia) cells, the former might represent either the normal counterpart of CLL or the earliest stages of the disease. Little information exists about both the clinical outcome of MBL^{lo} subjects and the biological features of their B-cell clones over time.
Aims: To gain insight into the biological and clinical significance of the presence of CLL-like MBL^{lo} clones, we re-evaluated the biological features of clonal B cells and the clinical outcome of MBL^{lo} individuals after 7 years of follow-up.
Methods: The baseline study was constructed in 2008, when 80 out of 639 (12.5%) healthy individuals (>40y) were found to carry at least one PB CLL-like clonal B-cell population, using high-sensitive flow cytometry. A subset of them (n=49) has been followed for a median period of 84 months (range: 67-95 months). Besides physical examination and flow cytometry analyses, the most frequent CLL-related cytogenetic alterations [del13q14.3(D13S25), trisomy 12, de11q(ATM) and del17q(TP53)] were studied at baseline and at follow-up.
Results: A total of 64 CLL-like MBL^{lo} clones (median size: 0.44 cells/ul, range: 0.027-66 cells/ul) were detected in PB of the 49 subjects at recruitment (in 15 cases ≥2 B-cell clones were detected in the same subject). In all subjects, B-cell clones persisted at reevaluation, phenotypically identical *vs* baseline. Interestingly, we found a near-3-fold overall increase in the size of CLL-like B-cell clones after a 7y follow-up *vs* baseline (median size: 1.22 cells/ul, range: 0.046-789 cells/ul; p:<0.001); in line with this, most clones (45/64; 70%) increased their size, while the remaining 30% maintained stable or slightly decreased numbers compared to time 0. From the genetic point of view, only 8/32 (25%) clones tested carried one cytogenetic alteration at baseline, del13q(D13S25) being present in 7/8 cases and trisomy 12 in the remaining one. Strikingly, re-evaluation after 7 years showed 36/56 clones (64%; p<0.01 *vs* baseline) with cytogenetic alterations; again, the most common abnormality was del13q(D13S25) (34/36) followed by trisomy 12 (1/36) and del 17p(TP53) (1/36). No statistical association (p>0.05) was found between the change over time in the size of these clones and the presence of cytogenetic lesions. Three subjects developed lymphocytosis (median: 5.3x10^{9}lymphocytes/l; range: 4.1x10^9-5.9x10^9/l) after 7 years; in these cases the clone size increased sub-

stantially over time and showed (2 of them) del13q14.3. Despite this, only 1/3 subjects evolved to more advanced stage of disease, who showed 5.9x10^{9}lymphocytes/l with >500 clonal B cells/ul (thus reaching MBL^{hi}) and del13q14.3.
Summary/Conclusions: Our results suggest that CLL-like MBL^{lo} is not a transient condition, as all clones detected at recruitment were systematically present also at follow-up with an increase frequency of cytogenetic lesions. Despite, B-cell clones slightly increased in size and even acquired cytogenetic abnormalities, the likely to progress into an over CLL seems to be extremely rare. Further research is needed to better understand the significance of CLL-like B-cell clones in healthy individuals and to clearly identify those MBL^{lo} subjects at risk to evolve to MBL^{hi}/CLL.

NUCLEAR LAMINA REGULATES SOMATIC HYPERMUTATION AND PROGRESSION OF B CELL MALIGNANCIES

T. Klymenko[1], J. Bloehdorn[2], J. Bahlo[3], S. Robrecht[3], J. Wang[1], K. Fischer[3], G. Akylzhanova[1], J. Edelmann[12], S. Estenfelder[2], J. Strefford[4], T. Wojdacz[4], M. Hallek[3], S. Stilgenbauer[2], M. Cragg[4], J. Gribben[1], A. Braun[1,*]
[1]Queen Mary University of London, London, United Kingdom, [2]University of Ulm, Ulm, [3]University of Cologne, Cologne, Germany, [4]University of Southampton, Southampton, United Kingdom

Background: The nuclear periphery, containing the IgH and IgK gene clusters, is a unique compartment comprised of inner nuclear membrane proteins and nuclear lamina. Previous genome-wide and cytological studies revealed the regulatory role for some of these nuclear proteins in higher level genome organisation and gene regulation. In particular, Lamina Associated Domains (LADs) were identified at the nuclear periphery as transcriptionally silent, gene-poor domains associated with Lamin B1. More recent studies however revealed an important role of LADs in the regulation of gene expression and recombination.
Aims: Given the apparent topological coincidence between LADs and Ig variable clusters, we hypothesised that nuclear lamina might play a paramount role in the dynamics of Ig-encoding variable genome domains. In particular, here we tested whether Lamin B1, a principal LAD-associated component of the nuclear envelope, had any restrictive role on somatic hypermutation (SHM) and the expression of Ig genes. Due to the strong involvement of IgV mutations in the pathogenesis of B-cell malignancies, we also tested whether nuclear lamina is involved in the pathogenesis of germinal centre lymphomas and chronic lymphocytic leukaemia (CLL).
Methods: We used BL2 and naïve B cells as *in vitro* and *ex vivo* models for somatic hypermutation. ChIP-Seq, ChIP-PCR and ImageStream analyses were performed to establish Lamin B1 genome and nuclear binding dynamics in resting and activated BL2 and B cells. LMNB1 RNAi was used to obtain the functional evidence of the involvement of Lamin B1 in SHM in vitro. For *in vivo* studies, OVA immunised mice were used to study Lamin B1 dynamics in *de novo* formed spleen germinal centres. From a translational perspective, paired tissue microarray samples of diagnostic and transformed follicular lymphoma were analysed using immunohistochemistry and image analysis. Finally, comprehensive statistical analysis of CLL8 cohort patients was performed to test the impact of LMNB1 expression on various clinical parameters in CLL.
Results: We have found that genome binding of Lamin B1, a component of the nuclear envelope involved in epigenetic chromatin regulation, is reduced during B cell activation and formation of lymphoid germinal centres. ChIP-Seq analysis showed that kappa and heavy variable immunoglobulin domains were released from the Lamin B1 suppressive environment when SHM was induced in B cells. RNAi-mediated reduction of Lamin B1 resulted in spontaneous SHM as well as kappa-light chain aberrant surface expression. Finally, Lamin B1 expression level correlated with progression-free and overall survival in chronic lymphocytic leukaemia, and was strongly involved in transformation of follicular lymphoma.
Summary/Conclusions: In summary, here we report that Lamin B1 is a negative epigenetic regulator of SHM in normal B-cells and a "mutational gatekeeper", suppressing the aberrant mutations that drive lymphoid malignancy.

P586

MICROENVIRONMENT REGULATION OF PROGRAMMED DEATH-1 (PD1) RECEPTOR AND ITS LIGANDS PDL1 AND PDL2 IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

San Martino-IST, Genoa, [21]Hematology Department, Annunziata Hospital of Cosenza, Cosenza, Italy

Background: The PD1 pathway is involved in the inactivation of immune effectors with potential reactivity against neoplastic cells in the tumor microenvironment (TME). PD1 binding to its ligand PDL1 inhibits proliferation, cytokine production, and cytotoxic activity of T-cell effectors. T-cells from CLL patients exhibit defective immunity, including impaired effector function leading to T-cell exhaustion. PDL1 checkpoint blockade restores immune dysfunction and impairs leukemia growth in the Eμ-TCL1 transgenic CLL mouse model. PD1/PDL1 ligation also affects BCR signaling, and because PD1 is also expressed on CLL cells, PD1 interference might directly influence tumor growth and proliferation directly. The PD1/PDL1 axis may be a therapeutic target, preferably in combination with BCR inhibitors (BCRi).
Aims: To investigate (1) expression of PD1 and PDL1/2 and their correlation with time to first treatment (TFTT); (2) the role of the TME in controlling the expression of the PD1 axis; and (3) the role of ibrutinib (IB) in the expression of PD1 and ligands.
Methods: CLL patients were prospectively enrolled at diagnosis (O-CLL1 protocol, clinicaltrial.gov identifier: NCT00917540). Gene expression (GE) analysis was performed using the GeneChipVR Gene 1.0 ST Array (Affymetrix) according to the manufacturer. Flow-cytometry (FC) was used to evaluate cellular phenotype (BD Biosciences) in an independent subset of patients. Lymph node samples from CLL patients were subjected to *in situ* immunolocalization analyses. Autologous T-cells (AAT) were obtained by *in vitro* exposure of patient T-cells with anti-CD3/CD28 and rIL2 in co-culture with CLL cells. Cultures were monitored daily until substantial clumping occurred and then tested for PD1 and ligand expression by FC. In selected experiments IB was added to cell culture.
Results: We evaluated GE of PD1 and PDL1/2 in 211 early-stage CLL patients. The impact of GE of PD1 and PDL1/2 on clinical outcomes in CLL cases [(n=211, median follow-up=39 months, range 6−82 months] indicated a significantly shorter TTFT in cases with higher levels of PDL2, while no significant impact was detected based on differences in PD1 or PDL1 gene levels. A Cox multivariate model showed that higher PDL2 gene expression retained an independent prognostic power (HR=1.9, 95%CI 1.1–3.4, P=0.022) in predicting TTFT together with IGHV-UM status, B-lymphocytosis≥5000/mm3 (P=0.020) and CD38 expression (P=0.021). *In situ* immunolocalization analysis of CLL tissue infiltrates indicated variable expression of PD1 mostly characterized small lymphoid elements,while PDL1 and PDL2 (with PDL2>PDL1) mostly characterized larger medium-sized elements within proliferation centers. Co-localization studies revealed PD1 co-expression on CD20+ CLL cells and in scattered CD3+ cells. Both ligands were variably expressed in CD20+CLL cells and few T-cells and macrophages showed expression of either ligand. AAT co-culture experiments showed a higher percentage of PD1+,PDL1+, and PDL2+ B-cells. Evaluation of T-cells detected an increase of CD3+, CD4+,and CD8+cells bearing both PD1 and PDL1,but not PDL2. IB (1uM) reduced the size of activated B- and T-cell clusters as well as PD1/PDL protein expression on CLL B-cells and only on the CD8+ T-cell subset.
Summary/Conclusions: Our findings indicate that expression of PDL2 characterizes a subset of high-risk early stage CLL patients. The expression of PD1/PDL1/PDL2 proteins is also characteristic of the CLL TME whereby, co-stimulatory signals derived from activated T-cells and/or the TME may modulate the PD1 axis, which is counteracted by IB.

P587

IL-4 INCREASES EXPRESSION OF POSITIVE REGULATORS OF BCR SIGNALLING IN CLL WHICH CAN BE OVERCOME BY CERDULATINIB

M. Blunt[1,*], R. Dobson[1], H. Amar[1], P. Conley[2], A. Pandey[2], G. Coffey[2], J. Strefford[1], F. Forconi[1], F. Stevenson[1], G. Packham[1], A. Steele[1]
[1]Cancer Sciences, University of Southampton, Southampton, United Kingdom, [2]Portola Pharmaceuticals, San Francisco, United States

Background: B cell receptor (BCR) mediated signalling is crucial for the pathogenesis of chronic lymphocytic leukemia (CLL). Drugs such as ibrutinib and idelalisib which inhibit BCR associated kinases have proved effective for the treatment of CLL but only suppress the disease without being curative. Some patients have developed resistance to these drugs following mutations, progress on therapy for unknown reasons, or cannot tolerate these drugs due to adverse events. We have shown that microenvironmental signals (*e.g.*, IL-4) can increase BCR expression and signalling, and can partially reverse the effects of BCR-kinase inhibition. GAB1, PTPN22 and FOXP1 can positively regulate BCR signalling in CLL; but the effect of IL-4 on these proteins has not previously been studied. Insight into how IL-4 promotes BCR signalling may allow the development of novel drugs that overcome resistance to kinase inhibitors. Cerdulatinib (cerd) is an inhibitor of both Syk (pivotal to BCR signalling) and JAK1/3 (integral for IL-4 signalling). Inhibition of Syk has been shown to induce apoptosis of CLL samples resistant to ibrutinib. Cerd is currently in phase II clinical trials in patients with relapsed/refractory B cell malignancies including CLL.
Aims: To investigate the effect of IL-4 on the regulation of BCR signalling in CLL and how this is modified by cerdulatinib
Methods: Eighteen primary CLL samples were treated with IL-4 +/-cerd (1μM) and expression of FOXP1, GAB1, PTPN22, SOCS1 and SOCS3 assessed by immunoblotting. The effect of cerd on apoptosis was assessed by flow cytometry and PI/Annexin V staining.
Results: Primary human CLL cells treated with IL-4 for 24hr significantly increased expression of positive regulators of BCR signalling FOXP1 and GAB1 in CLL samples with un-mutated IGHV (U-CLL); no change in expression in FOXP1 or GAB1 was seen in CLL samples with mutated IGHV (M-CLL). There was a 40% increase in PTPN22 expression in IL-4-treated U-CLL samples *vs* no change in M-CLL. Cerd, at therapeutic concentrations, blocked IL-4 mediated increases in FOXP1, GAB1 and PTPN22 and pSTAT6 (a positive control for IL-4 signalling). After 24hr IL-4 selectively increased expression of the negative regulators of IL-4 signalling, SOCS1 and SOCS3 in U-CLL, but not M-CLL cases, and this could be blocked by cerd. Cerd potently inhibited the signalling of other cytokines known to play a role in CLL biology (IL-6, IL-10, IL-15, IL-21 and IFNγ) which utilise either JAK1 or JAK3 for activation of STAT proteins. IL-4, CD40L and BCR ligation signals to CLL cells in lymph nodes can promote resistance to therapies such as the BCL2-inhibitor venetoclax. We have shown that cerd can overcome IL-4/CD40L induced expression of pro-survival proteins MCL1 and BCLxL and that cerd in combination with venetoclax induced apoptosis in a synergistic manner in the presence of IL-4/CD40L. We now extend these results to assess the important effect of this drug combination in the presence of BCR stimulation. The combination of cerd and venetoclax in the presence of either BCR signalling (bead immobilised anti-IgM) alone, or combined with IL-4 and CD40L, induced synergistic killing, with greater CLL cell death than with either drug alone.
Summary/Conclusions: These results provide evidence that IL-4 may increase BCR signalling by upregulating the expression of positive regulators of BCR signalling in U-CLL and that this can be overcome by cerd. These results support the continued use of cerd in clinical trials for the treatment of CLL, alone or in possible combination with venatoclax.

Eugenio Hospital and University of Tor Vergata, Roma, [7]Clinica Ematologica, Centro Trapianti e Terapie Cellulari "Carlo Melzi" DISM, Azienda Ospedaliera Universitaria S. Maria Misericordia, Udine, [8]Division of Hematology, Ferrarotto Hospital, Catania, Italy, [9]Department of Pathology and Cancer Center, University of New Mexico, Albuquerque, NM, [10]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Background: VLA-4 (CD49d/CD29), a key molecule mediating cell microenvironmental interactions, can be activated via inside-out by BCR triggering in normal B cells. In chronic lymphocytic leukemia (CLL), nothing has been so far reported regarding the VLA-4 activation mechanisms and their modulation by ibrutinib, a drug that is known to determine an impairment of microenvironmental interactions with consequent shrinkage of tumor masses, and efflux of CLL cells into the blood stream.
Aims: To investigate in CLL the influence of VLA-4 expression/activation on ibrutinib response in-vivo.
Methods: VLA-4 activation was assessed by flow cytometry using conformation sensitive anti-CD29 mAbs (HUTS-21) and LDV-containing VLA-4 ligands, and measured as VLA-4 receptor occupancy (RO) (Chigaev *et al.* J Biol Chem, 2009). BCR engagement was performed using goat F(ab)2 anti–human IgM. In-vitro studies were carried out on purified VLA-4+ CLL cells exposed in-vivo to ibrutinib. The clinical impact of VLA-4/CD49d expression on ibrutinib treatment was evaluated by measuring the kinetics of absolute lymphocyte count (ALC), the reduction of lymphadenopathy measured as sum of products of the diameters (SPD) % reduction from baseline, and the clinical outcome, as defined by progression free survival (PFS) in CLL patients treated with ibrutinib single agent in the context of name patients program, clinical trials, and real world (n=97).
Results: BCR stimulation (n=27) induced VLA-4 activation (mean RO control *vs* stimulated: 0.40 *vs* 0.52, p=0.0006), and increased cell adhesion (stimulated/control: 4.7 *vs* 7.5; p=0.0002). By comparing day 30 (t30) in-vivo ibrutinib-treated CLL cells with pre-treatment (t0), we show that the ibrutinib-dependent BCR signaling impairment, although reducing the constitutive VLA-4 activation (mean RO t0 *vs* t30: 0.40 *vs* 0.30, p=0.02) and CLL cell adhesion (mean adhesion t0 *vs* t30: 4.7 *vs* 2.1, p=0.013), was overcome by exogenous BCR triggering, which re-activated VLA-4 at levels similar to those of ibrutinib naïve cells (mean RO: 0.49 at t30 *vs* 0.52 at t0). ALC data were available at pre-treatment and at days 30-60-90-120 on ibrutinib in 97 patients (52 CD49d+) (Fig.1A); CD49d+ CLL showed no ALC rise, whereas CD49d- CLL showed the typical ibrutinib-induced ALC peak. At day 30 median % ALC change from baseline for CD49d- and CD49d+ CLL were 126.8% and -4.4% (p=0.0002). When comparing the extent of nodal response, available for 57 cases (30 CD49d+), a significantly minor % SPD reduction from baseline was observed in CD49d+ *versus* CD49d- CLL: 70.5% *vs* 83% (p=0.033) at 6 months and 81.5% *vs* 92.0% (p=0.019) at 12 months (Fig.1B). The impact of CD49d expression on patient outcome was evaluated in the whole cohort (median follow-up, 24.5 months). PFS was inferior in CD49d+ compared to CD49d- CLL (median PFS 39.3 months, *vs* not reached; p=0.004), even when considering the concomitant presence of *TP53* disruption and CD49d+ expression (Fig.1CD). A multivariate Cox regression analysis confirmed the relevance of CD49d, along with *TP53* disruption and UM *IGHV* mutational status, as independent predictor of shorter PFS in ibrutinib-treated CLL.

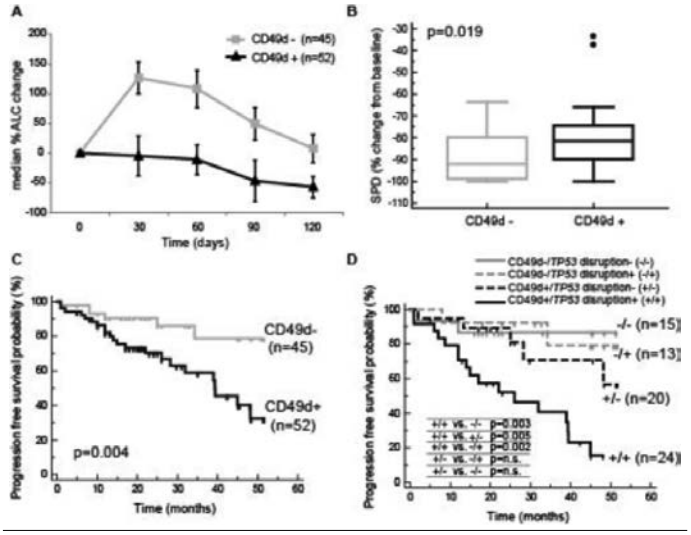

Figure 1.

Summary/Conclusions: Altogether, these data suggest that during ibrutinib treatment CD49d+ CLL cells residing in tissue sites keep receiving BCR-mediated BTK-independent stimuli that, by inducing inside-out VLA-4 activation, result in enhanced cell retention, with consequent reduced lymphocytosis, relatively lower and/or slower nodal response, eventually leading to inferior outcome for CD49d+ CLL patients.

P589

IBRUTINIB RESULTS IN REDUCTION OF PHOSPHORYLATION OF MULTIPLE KINASES IN THE B-CELL RECEPTOR PATHWAY IN CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL): RESULTS OF THE BLOODWISE TAP ICICLLE STUDY

Background: Ibrutinib is an oral Bruton tyrosine kinase (BtK) inhibitor which has advanced the clinical management of CLL. Ibrutinib binds irreversibly to the cysteine 481 residue of the BtK protein, rendering it inactive. Btk inhibition affects the phosphorylation of other intracellular kinases resulting in an immediate redistribution of CLL cells and subsequent apoptosis. We investigated the impact of ibrutinib on the phosphorylation of upstream and downstream kinases in the B-cell receptor pathway in real time in the IcICLLe study (ISRCTN12695354).
Aims: The IcICLLe trial was a single arm, multi-centre feasibility study of ibrutinib in two cohorts of CLL patients: (A) 20 treatment-naïve (TN) requiring treatment (according to IWCLL criteria); and (B) 20 relapsed/refractory (RR). All patients received continuous oral therapy with ibrutinib (420mg once daily) from registration until disease progression. The primary endpoint of the trial was the proportion of patients achieving minimal residual disease (MRD) negative remission (depletion of CLL ≤0.01% in peripheral blood (PB) & bone marrow (BM)) within 6 months of trial treatment. Exploratory endpoints included the assessment of phosphorylation of intracellular kinases in the B-cell receptor pathway.
Methods: A panel of markers was assessed on PB & BM taken at screening, and 1 & 6 months. PB was also taken at baseline (0 hours), 4 & 24 hours, 7 & 14 days, and 2, 9 & 12 months. The phosphorylation of SyK pY348, BtK pY551, ERK1/2, AkT S473 was assessed in 4 conditions at each time point: unstimulated +/- ibrutinib, and stimulated with IgM/IgD +/- ibrutinib. $1x10^6$leukocytes were tagged to extracellular antibodies (CD3/CD19) conjugated to fluorochromes. Ibrutinib (10uM) was added to the cells for 30 minutes at 37ºC followed by anti-IgM/IgD stimulation (10ug/ml). The BD phosflow protocol was followed to lyse/fix/permeate the CLL cells. Antibodies to BtK pY551, Syk pY348, ERK1/2 pT204/pY204, Akt pS473 were used tagged to fluorochromes (from BD Biosciences). Cells were acquired on a BD Fortessa flow cytometer.
Results: The phosphorylation of BtK, Syk, Akt and ERK1/2 was analysed in cells at the specified time points and conditions for 20 TN and 20 RR CLL patients. Baseline phosphorylation of all kinases was similar in both PB & BM. Phospho-BtK showed no stimulation on addition of IgM/IgD 4h after initiating therapy. There was a strong (2-4 fold) increase in phosphorylation of Syk kinase with IgM/IgD even in the presence of ibrutinib *in vitro*. This effect was profound in the first 2 months of ibrutinib therapy with a general decrease in phosphorylation after 6 months. Baseline stimulation of ERK1/2 gave a 1.5-2 fold increase in phosphorylation but the effect was abrogated within 1 month of ibrutinib therapy. Akt S473 phosphorylation was maintained after 6-12 months of therapy although the degree of phosphorylation decreased at later time points. Syk, AkT and ERK1/2 phosphorylation was unaffected by the addition of ibrutinib *in vitro*. The pattern of phosphorylation was found to be relatively consistent in responding patients. One patient with progressive CLL had sustained phosphorylation in all markers despite ibrutinib therapy.
Summary/Conclusions: The effect of ibrutinib on the phosphorylation of various kinases in the B-cell receptor pathway was analysed in real time. Syk continued to be phosphorylated over the course of treatment, which is logical as this kinase is upstream of BtK. That the degree of phosphorylation declined over time (even with stimulation) suggests a general inhibitory effect of ibrutinib on CLL cells. ERK1/2 phosphorylation is effectively blocked and there is partial reduction of phosphorylation of AKT S473. Combinations of BtK inhibitor with a Syk or PI3 kinase inhibitor may result in complete BCR blockade. Phosphorylation patterns may also act as an adjunct to ascertain the response to therapy.

P590

EVALUATION OF COMBINATIONAL THERAPIES FOR RELAPSED/REFRACTORY CLL WITH MUTATED P53

S. Post[1,*], H.J. Lee[2], H. Ma[1], M. Gallardo[3], X. Zhang[1], M. Hornbaker[1]
[1]Leukemia, [2]Lymphoma, MD Anderson, Houston, United States, [3]CNIO, Madrid, Spain

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with survival ranging from months to decades. CLL patients harboring *TP53* alterations are well known to be refractory to standard therapies; however, recent studies indicate that ibrutinib, a Bruton's tyrosine kinase (BTK) inhibitor, suppresses the B-cell receptor (BCR) signaling pathway and is an effective treatment option for these patients. Unfortunately, many patients with *TP53* alterations will ultimately fail ibrutinib-based therapies. Similarly, we have used a mouse model of refractory p53 mutant CLL (*Eμ-TCL1;p53^{R172H}*), and reported that while ibrutinib is effective in reducing the CD5+CD19+ population and extending survival, these mice eventually succumb to the disease (Lee HJ, *BCJ* 2016). These incomplete therapeutic responses indicate that ibrutinib provides only a temporary respite for this refractory disease, and highlights our need to develop more potent and targeted combinations.
Aims: Ibrutinib is effective in delaying (but not eliminating) leukemic progression in p53 mutant CLL, suggesting that combinational therapies that inhibit BCR signaling and activate apoptotic programs may be effective therapeutic strategies. Thus, agents that do not require activation of p53 but are effective in blocking oncogenic pathways (BTK and BCL-2) are attractive options. Currently, ibrutinib and ABT-199 meet this criteria and thus, we *hypothesize that simultaneous inhibition of the BTK- and BCL-2-pathways will be an effective strategy in treating p53 mutated CLL.*
Methods: To test this, we used RNA-Seq to examine expression changes in B-cells from *Eμ-TCL1* mice carrying either wild type or a single *p53^{R172H}* hotspot mutation (corresponding to *p53^{R175H}* in humans) following ibrutinib treatment. qRT-PCR and IHC were used to validate expression of key targets within pathways amenable to combinational therapy. Hematopoietic tissues were subjected to combinational therapies to interrogate efficacy.
Results: We have shown that ibrutinib downregulates the BTK- and ERK-pathways regardless of p53 status. However, less is known in regards to global expression changes in p53 mutant CLL following BTK inhibition. To investigate this, we performed RNA-Seq analyses using malignant B-cells from untreated and ibrutinib treated *Eμ-TCL1;p53^{R172H}* and *Eμ-TCL1* mice. Pathway analyses revealed that CLL cells harboring a single *p53* mutant allele retained a partial ability to activate p53-dependent programs. qRT-PCR revealed robust activation of p53-dependent anti-proliferative targets like p21, but only modest activation of pro-apoptotic targets (*e.g.*; *PUMA*), suggesting these p53 mutant CLL cells have a diminish capacity to activate apoptosis or overcome apoptotic inhibitors. To explore this altered bi-modal p53 activation, we performed IHC and observed that apoptotic activation was hampered by increased BCL-2 expression. To examine whether this BCL-2-dependent inhibition could be overcome, malignant B-cells were treated with ibrutinib alone, ABT-199 (a BCL-2 inhibitor) alone, or in combination. Here, we observed that ABT-199 was sufficient to activate apoptosis, regardless of p53 status, and that its use in combination with ibrutinib drastically reduced cell viability.
Summary/Conclusions: Together, these data indicate that patients with a partially attenuated p53 pathway may retain the ability to activate apoptosis if molecular barriers are removed (*e.g.*; BCL-2 via ABT-199). Furthermore, these results suggest that combinations with BTK- and BCL-2 inhibitors may be therapeutically beneficial for patients with mutated TP53.

Chronic myeloid leukemia - Biology

THE DNA REPLICATION PATHWAY HAS POTENTIAL PREDICTIVE VALUE FOR TKI RESPONSE AND THERAPEUTIC INTERVENTION IN CHRONIC MYELOID LEUKAEMIA

K. Yalla[1], H. Morrison[2], P. Toofan[1], L. Hopcroft[1], G. Horne[1], C. Munje[1], H. Moka[3], E. Gómez-Castañeda[1], S. O'Brien[4], M. Copland[1,*], H. Wheadon[1]
[1]Institute of Cancer Sciences, University of Glasgow, [2]West of Scotland Genetic Department, NHS, Glasgow, [3]National Heart and Lung Institute, Imperial College London, London, [4]Northern Institute of Cancer Research, University of Newcastle, Newcastle, United Kingdom

Background: Chronic myeloid leukaemia (CML) is a myeloproliferative disease which arises in a haemopoietic stem or multipotent progenitor cell with the t(9;22)(q34;q11) chromosomal translocation.Tyrosine kinase inhibitors (TKIs) were developed to target the constitutively active oncoprotein BCR-ABL, which is expressed as a result of this translocation. TKI therapy has significantly improved patient survival, however predicting response to therapy is one of the unmet clinical challenges in CML. Moreover, TKIs are unable to target the leukaemic stem cells (LSCs) which drive the disease; persistence of LSCs therefore remains a major obstacle to curing CML. Understanding the mechanisms that LSC employ to survive TKI treatment is necessary to design essential therapeutics to eliminate CML in the future.
Aims: To identify genes with predictive value for TKI response and to determine the efficacy of drug targeting one of the key pathways identified.
Methods: Microarray, Fluidigm, Real-time PCR, FACS based cell cycle and Annexin V apoptosis analysis, Trypan blue exclusion cell counts.
Results: Analysis of bulk CML patient microarray data (GSE 47927) identified 323 deregulated genes either in the stem cell population or during disease progression, important for self-renewal, DNA damage and repair, cell cycle and survival. These genes were validated in 60 samples from the SPIRIT 2 clinical trial [a multicentre phase III randomised trial comparing the TKI imatinib (400mg daily) *versus* Dasatinib (100mg Daily)] with 18 months follow-up data regarding molecular response to TKI treatment. Patients were stratified as good/intermediate/poor responders to TKI and the gene signature significantly differentially expressed was identified. These data highlighted the DNA repair genes as having potential predictive value, in particular, the minichromosome maintenance (MCM) protein and origin of replication (ORC) family of genes, involved in DNA replication and cell cycle regulation. Single cell analysis of CD34+ cells across the patient cohort identified considerable heterogeneity of expression of MCMs and ORCs, with ORC3, in particular, exhibiting a different expression profile in good/intermediate/poor responders (n=3 of each). In addition single cell analysis highlighted a significant difference in the expression of MCM2, -4, -7 & ORC2 in the most primitive LSC (CD34+38-90+93+) compared to CD34+38-90+93- cells. Next, we investigated the ability of heliquinomycin (HQ), a potent helicase inhibitor of MCM on its own and in combination with IM to target the CML cell line K562. Our extensive dose and time response studies followed by FACS-based apoptosis and cell cycle analysis prove the potency of HQ and its synergistic action in combination with imatinib. We also investigated the changes in a panel of cell cycle and DNA damage response genes at the transcript level in response to HQ and imatinib in the K562 cell line. Overall the data generated indicates that targeting the MCM pathway in combination with BCR-ABL inhibition is a rational approach for future therapeutic intervention in CML.
Summary/Conclusions: Global 'omics' experimental approaches are valuable for identifying novel pathways deregulated in CML. This combined with single cell 'omics' studies enables the heterogeneity of gene expression and the response of individual LSCs to TKI to be evaluated. Our data indicate that the DNA replication pathway plays an important role in CML, with levels of MCMs and ORCs having potential predictive value in TKI response and are a promising drug target in CML.

SIGNAL TRANSDUCING ADAPTOR PROTEIN-1 (STAP-1) MAINTAINS CHRONIC MYELOID LEUKEMIC STEM CELLS

J. Toda[1,*], M. Ichii[1], K. Oritani[1], H. Saito[1], Y. Kitai[2], R. Muromoto[2], J.-I. Kashiwakura[2], K. Saitoh[2], T. Matsuda[2], Y. Kanakura[1]
[1]Department of Hematology and Oncology, Osaka University Graduate School of Medicine, Osaka, [2]Department of Immunology, Graduate School of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan

Background: Signal transducing adaptor protein (STAP) -2 was cloned as a c-fms binding protein. Previously, we have demonstrated that STAP-2 binds to BCR-ABL, which is constitutively activated in chronic myeloid leukemia (CML), via its SH2-like domain and enhances BCR-ABL activity leading to activation of downstream molecules, including ERK, STAT5, BCL-xL and BCL2. The family of STAPs includes STAP-1, identified as a c-kit interacting protein, and STAP-2. While STAP-2 is expressed ubiquitously, STAP-1 has hematopoietic-specific expression in mice. It is still unknown whether STAP-1 plays a role in CML, although STAP-1 is expected to have similar functions based on the structural homology between STAP-1 and STAP-2.
Aims: To elucidate the role of STAP-1 in CML using mouse model and human samples.
Methods: We generated STAP-1 deficient mice of the C57BL/6J genetic background. For establishment of CML mouse model, we isolated Lineage (Lin)$^-$ Sca-1$^+$ c-kit^{high} (LSK) fraction of bone marrow (BM) cells from STAP-1$^{+/+}$ and STAP-1$^{-/-}$mice, infected them with retrovirus carrying MSCV-BCR-ABL-ires-GFP, and transplanted into congeneic recipients, that were named Wild type (WT) and STAP-1$^{-/-}$CML mice, respectively. Human BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital.
Results: Using Western blot and immunoprecipitation assay, we confirmed that STAP-1 binds to BCR-ABL. CML mice model was then employed to analyze the role of STAP-1. We found that STAP-1$^{-/-}$ CML mice showed significantly longer survival than WT CML mice (Fig. 1). STAP-1$^{-/-}$ CML mice displayed less severe splenomegaly and lung hemorrhages compared to WT, suggesting that loss of STAP-1 attenuates CML progression. To investigate how STAP-1 regulates CML progression, we evaluated leukemic stem cells (LSCs) in CML mice. The absolute numbers of STAP-1$^{-/-}$ LSCs (GFP+ LSK) in BM and spleen were significantly lower than those of control (WT *vs* STAP-1$^{-/-}$; 2090.3 ± 694.07 cells *vs* 412.57 ± 114.07 cells in BM, p=0.0291; 12.9 ± 1.75 ×10^4 cells *vs* 4.09 ± 0.72 ×10^4 cells in Spleen, p=0.0009). In colony-forming assay *in vitro*, STAP-1$^{-/-}$ LSCs generated less colonies in the first and second plating compared to WT LSCs. These data indicated that deletion of STAP-1 would impair self-renewal capacity of LSCs. When we transplanted 5,000 LSK cells from STAP-1$^{+/+}$ or STAP-1$^{-/-}$ mice without BCR-ABL transduction in the presence of competing BM cells, deletion of STAP-1 had no effects on engraftment at 28 days after transplantation. Furthermore, we measured the expression of STAP-1 in BM cells derived from patients in the chronic phase of CML. As a result, STAP-1 mRNA was abundant in the LSC (CD34$^+$ CD38$^-$ Lin$^-$) compartment.

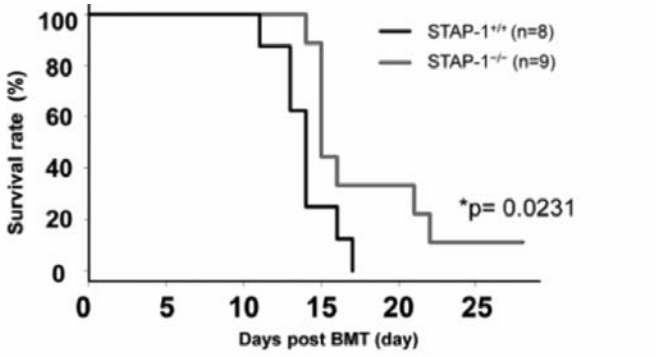

Figure 1.

Summary/Conclusions: In this study, we utilized CML mouse model and showed that STAP-1 is required for progression of CML. Our findings indicate that STAP-1 has an indispensable role in LSC maintenance, while normal hematopoietic stem/progenitors were not affected by STAP-1 deficiency. Although a majority of patients have a durable response to BCR-ABL tyrosine kinase inhibitors, the outcome of patients who fail the treatment due to primary or acquired resistance is still miserable. Our findings in mice and human suggests that STAP-1 could be a therapeutic target for CML. Further analysis will be needed to clarify the molecular mechanisms by which STAP-1 regulates the progression of CML and maintains survival of LSCs.

P593

TELOMERE SHORTENING IN CD34+38- BCR-ABL POSITIVE BONE MARROW CELLS FROM NEWLY DIAGNOSED PATIENTS WITH CML CORRELATES WITH THE CLONE SIZE OF THE LEUKEMIC STEM CELL COMPARTMENT

A.-S. Bouillon[1,*], M. Ventura Ferreira[1], S.A. Awad[2], J. Richter[3], H. Hjorth-Hansen[4], S. Hummel[1], M. Schemionek[1], S. Mustjoki[2], F. Beier[1], T.H. Brümmendorf[1]
[1]Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Medical Faculty, Uniklinik RWTH Aachen, Aachen, Germany, [2]Hematology Research Unit, University of Helsinki, and Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland, [3]Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden, [4]Department of Hematology, St Olavs Hospital, Norwegian University of Science and Technology (NTNU), Trondheim, Norway

Background: Chronic myeloid leukemia (CML) is a clonal stem cell disorder characterized by the BCR-ABL translocation. Previous work provides evidence that based on the size of the leukemic stem cell (LSC) clone within the CD34+38- population at diagnosis, chronic phase (CP) of CML can be stratified into early and late CP. Patients in late CP have a higher LSC burden going along with an inferior response to TKI therapy. Telomeres shorten with each

cell division and telomere length (TL) in peripheral blood cells has been shown to correlate with disease stage, response to treatment and duration of CP in CML patients. However, the use of TL as a routine clinical biomarker in CML has been complicated by considerable inter-individual, mostly genetic variability in TL ideally requiring non-clonal control cells.
Aims: Based on these considerations, we used a modified Q-FISH technique in order to be able to separately study TL directly in BCR-ABL+ LSC *vs* BCR-ABL- control cells within the CD34+38- hematopoietic stem cell compartment of diagnostic patients with CML in CP.
Methods: 15 patients (median age: 59 years, range: 41- 72 years) diagnosed with CML in CP of the NCT00852566 study (Nordic CML Study Group) were retrospectively analyzed. Of the patients studied, clinical data were available for 14 patients. Of those, 2 (14%) belonged to the Sokal high risk group, 5 (36%) to intermediate and 7 (50%) to the low risk group. CD34+38- cells sorted from bone marrow samples were tested with the standard FISH method using dual fusion dual color BCR-ABL1 probe following standard procedures. After capturing the BCR-ABL staining using confocal microscopy, samples were re-processed for TL analysis by Q-FISH using established protocols. TL staining was analyzed in all previously captured cells allowing the identification of BCR-ABL+/- cells within the same sample. Analysis and quantification of BCR-ABL FISH staining and TL measurement by Q-FISH were performed in blinded fashion.
Results: Overall, we observed significantly shortened TL in the BCR-ABL+ compared to BCR-ABL- cells (-4.9 arbitrary units (a.u.) range: -53.7 to 16.9 a.u., p=0.04). Next, we correlated the clone size (i.e. the proportion of BCR-ABL+ positive cells within the CD34+38- compartment) with the degree of telomere shortening in LSC. Mean clone size of the patients was 59.9 ± 32.0 % S.D. Of note, we found a significant negative correlation (R^2=0.36, p=0.02) between TL and clone size strongly supporting the notion that increased expansion of the BCR-ABL+ LSC pool leads to accelerated telomere shortening. Correlation with clinical prognostic data such as Hasford (R^2=0.07, p=0.41) or Sokal (R^2=0.04, p=0.38) score did not reveal any statistically significant correlation with the degree of telomere shortening probably due to the small sample size analyzed in this pilot study.
Summary/Conclusions: In this study, we provide further evidence for accelerated telomere shortening in BCR-ABL+ LSC as compared to their normal CD34+CD38- counterpart in CP CML samples at diagnosis. Interestingly, the degree of TL shortening linearly correlates with the clone size of the BCR-ABL+ LSC compartment. Thus, this retrospective study (now on the LSC level) further supports a role of TL as a prognostic and predictive biomarker in newly diagnosed patients with CML pending confirmation in prospective trials.

[1]Department of Immunology, [2]Postgraduate School of Molecular Medicine, Medical University of Warsaw, [3]Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, [4]Department of Hematology Diagnostics, The University Hospital, Cracow, [5]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, [6]Department of Hematology, Jagiellonian University, Cracow, [7]Department of Internal Diseases and Hematology, Military Institute of Medicine, [8]Department of Hematology, Oncology and Internal Diseases, Medical University of Warsaw, [9]Department of Patology and Laboratory Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute, [10]Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland, [11]Department of Microbiology and Immunology, Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, United States

Background: Blastic phase of chronic myeloid leukemia (BP-CML) remains mostly incurable even with newer generation tyrosine kinase inhibitors (TKI) and represents an unmet clinical need. Although in recent years a dramatic reduction in the transformation of chronic phase (CP-CML) to BP-CML has been observed, still up to 5% of patients will progress to BP-CML despite treatment with TKI. Prospective identification of such patients may have a significant clinical impact. There are only few reports to date which use next-generation sequencing (NGS) to look for somatic mutations - other than those affecting kinase domain of *BCR/ABL1* - at the time of diagnosis (Dx) which could have a prognostic/predictive value.
Aims: We analyzed the spectrum of somatic mutations in two groups of CML patients with clinically different disease course: first group (BP) comprised of 11 patients who progressed to BP-CML despite treatment with TKI and/or allo-HSCT (one patient) and died (paired samples from Dx and BP were analyzed); second group (MMR) included Dx samples from 36 patients who achieved major molecular response (MMR) on TKI within 6 months and remained in MMR for at least 48 months from Dx.
Methods: Targeted enrichment strategy using custom designed capture probes (SeqCap EZ, Roche NimbleGen) followed by NGS on Illumina platform was employed. More than 1200 genes implicated in human cancer were included. Common variants (>1%) gathered in large genomic databases and our internal database were filtered out and the subsequent analysis was focused on putative protein damaging variants, supported by variant effect prediction tools such as PolyPhen-2, SIFT or CHASM. All reported variants were reconfirmed by Sanger sequencing.
Results: BP group comprised of paired samples from 11 CML patients who progressed to BP and died despite treatment with TKI. Median age at diagnosis was 53y (range 26 -77), median time to progression for 9 patients (2 were diagnosed in accelerated phase or BP) was 17,5 months (mo) (range 4-108) and median survival was 22 mo (range 10 -116). None of those patients harbored *BCR/ABL1* mutation at the time of Dx and progression to BP-CML, 4 patients had additional chromosomal alterations at progression to BP including two frequent (trisomy 8 and monosomy 7). Targeted enrichment followed by NGS allowed us to achieve deep coverage (>80% ge50). Median number of rare variants was 26 (range 18-38) and 29 (range 23-32) for Dx and progression samples respectively. In majority of patients upon progression (72%, 8/11) we detected new and previously described mutations in selected genes, which are frequently mutated in myeloid malignancies, namely in *RUNX1* (36%, 4/11), *DNMT3A* (27% 3/11) *IDH1/IDH2 (18%, 2/11)* and *ASXL1* (18%, 2/11). In six patients (54%, 6/11) mutations in these genes (excluding *IDH2,* detected only in BP sample) were preexisting at the time of Dx. These results were compared to second, control group that comprised of diagnostic samples from 36 patients (median age at diagnosis 53y, range 23 -75) who were optimal responders to TKI and remained in MMR for at least 48mo (median time in MMR: 73mo; range 48-128). In MMR group, the median number of rare variants was lower than in BP group in Dx samples (21, range 14-32). However, in 2 patients (2/36, 5%) frameshift mutation in *ASXL1* (p. Gly643_Gly644fs) was detected, identical as in one of BP patients. Additionally, one patient harbored *RUNX1* mutation (p. Arg201Gln) which was not detected in the BP group.
Summary/Conclusions: Our results provide new insights into the already complex genomic landscape of blastic phase of CML. We suggest that a significant number of patients with poor disease outcome may harbor preexisting mutations in *DNMT3A, RUNX1* and *IDH1.* In contrast, mutations in *ASXL1* may be present at Dx in patients who will remain in long-term remission.

P595

INCREASED INDOLEAMINE 2,3-DIOXYGENASE (IDO1) ACTIVITY IN EARLY CHRONIC PHASE CHRONIC MYELOGENOUS LEUKEMIA (CML-CP) IS REDUCED BY NILOTINIB THERAPY AND PREDICTS MOLECULAR RESPONSE

S. Sopper[1,*], S. Mustjoki[2], G. Gastl[1], Z. Trajanoski[3], F. Giles[4], A. Hochhaus[5], J. Janssen[6], S. Geisler[7], D. Fuchs[7], D. Wolf[8]
[1]Hematology and Oncology, Medizinische Universität Innsbruck, Innsbruck, Austria, [2]Comprehensive Cancer Center, Helsinki University Hospital, Helsinki, Finland, [3]Bioinformatics, Medizinische Universität Innsbruck, Innsbruck, Austria, [4]Northwestern University, Chicago, United States, [5]Universitätsklinikum Jena, Jena, Germany, [6]Vrije Universiteit Medical Center, Amsterdam, Netherlands, [7]Biological Chemistry, Medizinische Universität Innsbruck, Innsbruck, Austria, [8]Hematology, Oncology and Rheumatology, University Hospital of Bonn, Bonn, Germany

Background: Indoleamine 2,3 dioxygenase (IDO1) is the rate-limiting enzyme in the metabolism of the essential amino acid tryptophan (TRP). IDO1 is induced mainly by interferons during infection and inflammation. Strong IDO1 activity depletes tryptophan, which results in reduced T cell activation and proliferation as well as expansion of immunosuppressive regulatory T cells. Deregulation of IDO1 activity has been linked to cancer immune evasion, but its role in chronic phase (CP) CML has not been investigated in detail.
Aims: Determination of IDO1 levels and activity in plasma CML-CP patients in the course of tyrosine kinase inhibitor therapy and their correlation with clinical and immunological parameters as well as molecular response.
Methods: A large panel of circulating cytokines and components of the IDO-pathway (soluble IDO1=sIDO1 and kynurenine/tryptophan ratio=KYN/TRP as a product of IDO1 activity) as well as various leukocyte populations such as plasmacytoid dendritic cells (pDC) were analyzed alongside the prospective pan-european ENEST1st clinical study (NCT01061177). This substudy included 52 nilotinib-naïve chronic phase (CP)-CML patients that were subsequently treated with 300mg BID nilotinib and longitudinally analyzed at months 6 and 12 of therapy. Molecular responses were quantified in central EUTOS reference laboratories.
Results: Soluble IDO (sIDO1) levels and KYN/TRP ratio are significantly upregulated in newly diagnosed CP-CML and drop during nilotinib therapy. sIDO1 levels significantly correlate with increased KYN/TRP, suggesting increased IDO1 activity at diagnosis. Increased sIDO is linked to a pro-inflammatory status in CML patients, as it positively correlates with increased serum neopterin levels as well as to various other pro-inflammatory markers, such as IFN-g, IL-8, IL-10, IL-17A, sVEGF-A, sVCAM-1 and sTNFR-1. Albeit being an IFN-regulated gene, IDO1 activity (KYN/TRP) negatively correlates with the proportion of pDC, the main producers of IFN-α. Interestingly, a higher KYN/TRP is linked to superior molecular response, as demonstrated by a significant correlation

of the KYN/TRP ratio to BCR-ABL transcript levels. Patients having a high KYN/TRP ratio (> mean +2SD of post therapy levels) reach deep molecular response rates (i.e. $MR^{4.5}$) significantly earlier and at higher rates. Moreover, combining KYN/TRP with sCD62L levels, a recently identified predictive biomarker, resulted in a score robustly predicting the odds of achieving deep molecular response.

Summary/Conclusions: CML diagnosis in CP is linked to an increased inflammatory status, as shown by increased levels of sIDO and its metabolites kynurenine leading to an increased KYN/TRP ratio. In solid cancer increased IDO expression/activity is linked to inferior outcome by favoring immune evasion. In contrast, in CML an increased KYN/TRP ratio is associated with improved molecular outcome during nilotinib 1st-line therapy. One reason could be that IDO activity may reflect endogenous IFN-α production, a known factor favoring immune-mediated CML-control. The predictive potential of KYN/TRP is currently verified in an independent cohort.

BCR-ABL1 COMPOUND MUTANTS DISPLAY DIFFERENTIAL AND DOSE-DEPENDENT RESPONSES TO PONATINIB

K. Byrgazov[1,*], C. Lucini[1], D. Printz[1], M. Koenig[1], P. Valent[2], O. Hantschel[3], T. Lion[1]

[1]Children's Cancer Research Institute, [2]Medical University of Vienna, Vienna, Austria, [3]Swiss Institute for Experimental Cancer Research, Lausanne, Switzerland

Background: Despite the dramatic improvement of prognosis in CML patients due to the introduction of tyrosine kinase inhibitors (TKIs), resistance to therapy occurs in a considerable proportion of patients. The best-characterized mechanism of resistance is the acquisition of mutations in the BCR-ABL1 tyrosine kinase domain (TKD) affecting TKI binding. The third-generation TKI ponatinib exerts strong anti-neoplastic effects even in advanced CML stages and is capable of suppressing the kinase activity of BCR-ABL1 carrying any single mutation including T315I. Nevertheless, resistance to ponatinib can evolve in sub-clones carrying BCR-ABL1 variants with two or more mutations on the same allele, if the IC_{50} values for this TKI exceed the maximum achievable effective plasma levels (efC_{ave}). These co-called compound mutations (CMs) are associated with increased oncogenic potential in comparison to individual mutations, and represent a powerful mechanism of potential resistance to all currently available TKIs. The occurrence of compound mutations has been linked particularly to sequential treatment with different TKIs, and the identification of their responsiveness to ponatinib is of paramount importance for the subsequent clinical management.

Aims: 1. To determine the spectrum of highly TKI-resistant CMs. 2. Measure the responses of BCR-ABL1 CMs to ponatinib

Methods: We have established a BCR-ABL1 protein model facilitating assessment of the presumptive impact of 27 different CMs involving important functional sites of the BCR-ABL1 TKD, and including constellations expected to display high resistance to ponatinib. To assess the anticipated responses to ponatinib in vitro, we have introduced all BCR-ABL1 CMs into Ba/F3 cells using a recently published transposon-mediated approach (Byrgazov *et al.*, Oncotarget 2016, 7(47):78083-78094), and IC_{50} values of ponatinib were determined.

Results: Most CMs involving sites with no previous evidence for implication in resistance to ponatinib displayed IC50 values below 10 nM. This efC_{ave} is readily achievable even with the 15mg daily dose of ponatinib. CMs revealing elevated resistance to ponatinib *in vitro* almost invariably included T315I or F317L mutations. While most CMs involving T315I revealed very high IC50 values, some of the predicted compound mutations containing F317L displayed an IC50 for ponatinib in the range of the efC_{ave} achievable only with a daily dose of 45mg. These observations are supported by clinical findings in the PACE trial which revealed impaired responses of patients with CMs involving F317L who had received average daily doses of ponatinib below 45mg (Deininger *et al.*, Blood 2016, 127(6):703-12).

Summary/Conclusions: Current strategies that aim at decreasing the dose of ponatinib to prevent severe side effects should carefully consider the presence and type of mutations in the BCR-ABL1 TKD to enable effective treatment. It would be highly desirable, therefore, to implement testing of the effective plasma drug concentrations and monitoring the kinetics of mutant subclones covering also compound mutations in the routine diagnostic surveillance to provide a basis for optimized clinical management of patients treated with ponatinib.

IS THERE EFFECTIVE IMMUNE SURVEILLANCE AGAINST CHRONIC MYELOID LEUKAEMIA? NO

R.P. Gale[1,*], G. Opelz[2]

[1]Haematology Research Centre, Imperial College London, London, United Kingdom, [2]Institute of Immunology, University of Heidelberg, Heidelberg, Germany

Background: *Immune surveillance* refers to a process whereby the innate and adoptive immune systems recognize and eliminate cancer cells on the basis of cancer-specific or related antigens or other molecules. Substantial data support the concept of immune surveillance in rodents but data in humans are less convincing and apply mostly to virus-induced cancers. However, considerable data indicate a strong anti-leukaemia effect in persons with chronic myeloid leukaemia (CML) receiving an allogeneic haematopoietic cell transplant. Most, if not all, of this anti-leukaemia effect is confounded with graft-versus-host disease (G*v*HD) and whether there is a allogeneic or host specific anti-leukaemia effect distinct from G*v*HD is controversial. Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance.

Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance.

Aims: Another interesting observation is about 40 percent of persons with CML and a deep molecular response to tyrosine kinase-inhibitors (TKIs) remain in molecular remission when TKI-therapy is stopped. Because TKI-therapy is very unlikely to eradicate every CML cell, some ascribe this therapy-free remission (TFR) a result of immune surveillance.

Methods: To test these hypotheses, we studied whether there was an increased incidence in CML in persons receiving immune suppression after solid organ transplants. IF immune surveillance is important in CML we would expect an increased incidence in this setting. We used a dataset from the Collaborative Transplant Study (CTS) which collects information on recipients of solid organ transplants beginning in 1985 from >300 transplant centers worldwide. Cancer incidence data were checked annually by questionnaire. Data for expected CML incidence were obtained from a cohort of identical size matched for age and sex from *Cancer Incidence in Five Continents* monitored for the same duration as the transplant cohort. Data collection and processing were approved by the Data Protection Agency in Germany and all participating centers complied with local ethical and privacy regulations.The CTS dataset consisted of 441,332 recipients of kidney (N=355,606), liver (N=47,846) and heart (N=37,880) transplants. Amongst kidney transplant recipients the standardized incidence ratio (SIR) for developing CML was 1.54 (95% confidence interval, 1.1, 2.1; p=0.01) representing 39 cases in 1,682,491 person-years at-risk *vs.* 25 expected (14 excess cases). Amongst liver transplant recipients the SIR was 1.72 (0.6, 4.0; P=0.34) representing 5 cases in 182,833 person-years at-risk *vs.* 3 expected (2 excess cases). Amongst heart transplant recipients the SIR was 3.47 (1.8, 6.1; p=0.0005) representing 12 cases in 173,015 person-years at-risk *vs*. 3 expected (9 excess cases). Data from recipients of kidney and liver transplants suggest immune-suppression does not increase risk of developing CML or does so very slightly. The increase in SIR in kidney graft recipients is generally-attributed to increased cancer surveillance including blood testing. Although the SIR of CML was substantially-increased after heart transplants, these persons receive high doses of ionizing radiations for diagnostic radiological procedures such as computer tomography (CT)-angiography. Ionizing radiations are a proved cause of CML which might explain the increased SIR.
Results: Our data, 25 excess cases of CML in 2,038,339 person-years at-risk observation suggest the magnitude of immune-surveillance do not support the hypothesis immune surveillance operates to an important extent to prevent CML in humans.
Summary/Conclusions: Consequently, the anti-leukaemia effect associated with allotransplants and the TFR observed after stopping TKI-therapy is unlikely to result from effective immune surveillance against CML.

MUTATIONAL ANALYSIS IN BCR-ABL1 POSITIVE LEUKEMIA BY DEEP SEQUENCING BASED ON NANOPORE MINION TECHNOLOGY

C. Minervini[1], C. Cumbo[1], P. Orsini[1], L. Anelli[1], A. Zagaria[1], A. Minervini[1], N. Coccaro[1], G. Tota[1], L. Impera[1], A. Russo Rossi[1], A. Ricco[1], C. Brunetti[1], P. Casieri[1], G. Specchia[1], F. Albano[1,*]
[1]Hematology - University of Bari, Bari, Italy

Background: In newly-diagnosed chronic phase (CP)-CML patients, 15–30% who start first-line tyrosine kinase inhibitors (TKIs) therapy will not reach an optimal response, and a BCR-ABL1 kinase domain (KD) mutation will be detectable in 25–50% of patients with treatment failure with an increased frequency of these mutations observed in accelerated phase and blast crisis patients. Currently, Sanger sequencing (SS) technique analyzing BCR-ABL1 is considered the gold standard for mutation detection knowing that this assay has a sensitivity of around 20 %, and therefore is unsuitable for identifying low-level variants (<20 % variant frequency). Recently next generation sequencing (NGS)-based assays have been reported for detecting BCR-ABL1 KD mutations; although these NGS strategies are more accurate and precise than SS, they are burdened by costs related to the initial investment, that is the sequencer purchase, the preparation of specific targets libraries, and the required reagents. MinION is a single molecule sequencer connected to a laptop through a USB3.0 interface, based on nanopore technology; it works by connecting two strands of DNA molecules by a hairpin, and sequencing them consecutively.
Aims: We describe a third- generation sequencing assay on MinON for detecting BCR-ABL1 KD mutations and compare the results to a SS-based test in 24 Ph+ leukemia cases.
Methods: Overall, 24 patients were included; among them, 12 (11 CML and 1 ALL cases) developed treatment resistance during the TKI's treatment course (Group 1) and 12 were at diagnosis (7 CML and 5 ALL cases) (Group 2). For ABL1 amplification and barcoding the total cellular RNA was extracted from peripheral blood cells. MinION library preparation, sequencing and data analysis were performed. All cases included in the study were analyzed by SS and MinION sequencing in blinded manner.
Results: Two sequencing runs were performed with the two different pools of patients: the first lasted eight hours and was carried out on the Group 1, whereas the second run included the Group 2 and lasted 24 hours to achieve a deeper sequencing. Sequencing results showed that 100% of ABL1 from exon 2 to 10 was covered and that the mean of the sequencing depth was around 150x and 1000x for Group 1 and 2, respectively. In any case, the depth of sequencing was never found below 50X. We found 10 BCR-ABL1 KD mutations in 9 patients belonging to the Group 1 (one case showed compound mutations). Notably, almost all mutations had a high allelic ratio. Despite a high depth of sequencing, MinION data analysis on the Group 2 was able to detect mutation only in a ALL case. Results from MinION and SS showed 92% concordance in all cases included in this study. Notably, mutations that were initially undetectable by SS became evident thanks to the indications coming from MinION analysis.
Summary/Conclusions:. Our findings demonstrate multiple advantages by using MinION approach, first of all the sensitivity: our comparison of MinION to SS identified mutations below the detection limit of SS (generally stimated around <20%) in 2 (22%) among the mutated cases, including mutations known to be clinically important. Another point on the side of the nanopore technology is the costs profile. Therefore, the main advantage of this technology is to allow a more efficient and sensitive analysis than SS at very competitive costs. In conclusion, we demonstrated that MinION is suitable for employment in hematology laboratory for detecting BCR-ABL1 KD mutation in Ph+ leukemias.

Background: The chronic myeloid leukemia (CML) is characterized by the presence of the Philadelphia chromosome and the BCR-ABL1 fusion gene. The introduction of tyrosine kinase inhibitors (TKIs) significantly improved the survival, but 15% of patients don't reach the optimal responses at the defined end-points or develop secondary resistance. The 2013 ELN guidelines identified as fundamental the early molecular response (BCR-ABL1/ABL1 % ≤10% IS), the MR3 (<0.1%) and the deep molecular response (MR4<0.01%, MR4.5<0.032%, and MR5 <0.001%). Consequently, the molecular monitoring plays a crucial role in the clinical management of CML patients, with a consequent research of sensitive and standardized molecular techniques. The automated methods offer advantages in terms of reduced time for analysis, decreased manual steps, and reduction of possible errors and contamination.
Aims: We compared the automated technique GeneXpert "Ultra" (Cepheid, Maurens-Scopont, France) with the "Labnet" method that includes the "classical" manual real-time PCR techniques standardized in the Italian network (57 centers), according to the European guidelines [Cross N, 2015]. We compared the sensitivity of the two methods (based on the number of ABL1 detected copies), the classification of molecular responses, with particular attention to the deep molecular one.
Methods: We assessed the BCR-ABL1 transcript in 86 patients afferent to laboratories of Pisa, Napoli, Torino, and Bologna (Italy). For statistical analysis, the *t*-, the Pearson's and the Cohen's K test were adopted. Because our patients presented different transcript levels (from the >10% to the 0% (MR4, MR4.5, MR5) the two techniques have been compared in the different molecular subgroups.
Results: Firstly we compared the number of detected ABL1 copies, that are fundamental for definition of the molecular response categories, especially for defining the degree of deep response (32,000 for MR4.5, 100,000 for MR5). By the "LabNet" method, 51 (81%) samples exceeded the 100,000 copies of ABL1, while by the automated method 81 samples (94.2%) reached >100,000 ABL1 copies. Then, we compared the two methods in discriminating positive and negative samples (K Cohen=0.690; p <0.02): 77 samples were concordant (89.5%) and only 9 (10.4%) were discordant. Of the 18 negative samples with the "LabNet" method, 2 (11.1%) were in MR4.0, 10 (55.5%) in MR4.5 and 6 (33.4%) in MR5.0. On the other hand, of the 19 negative samples with the method "Ultra", 1 (5.3%) was in MR4.5 and 18 (94.7%) in MR5.0, confirming the higher sensitivity of the automated method. In the cohort of positive cases by the two methods, the median values of transcript expression were superimposable (p=0.55) and the linear regression coefficient was very satisfying (Pearson's r=0.9399; p-value <0.0001). Finally we compared the results produced by the two methods according to the "molecular classes" (MR1 *vs* MR2+MR3 *vs* MR4+MR4.5 *vs* MR5). This comparison showed a good concordance between the two methods (Cohen's k=0.78–good correlation). Variation analysis demonstrated high concordance between "Ultra" and "LabNet" methods using assay comparison criteria proposed by Müller *et al.* [Leukemia 2009] (Table 1).

Table 1.

Category	Sample	Percentage	EUTOS Criteria
Less than 2-Fold Difference	49	77.7%	>50%
Less than 3-Fold Difference	56	88.8%	>75%
Less than 5-Fold Difference	60	95.2%	>90%
Greater than 5-Fold Difference	3	4.8%	NA
Total Samples Analyzed	63	100%	NA

Summary/Conclusions: In a huge series of patients the automated and manual molecular methods, applied in 4 different laboratories, resulted comparable in terms of classification of patients in "molecular classes". The advantage of the "Ultra" technique is represented by the higher number of detected ABL1 copies and the easier standardization.

P600

ROLE OF THE AURORA KINASE A/PLK 1 AXIS INHIBITION IN RESTORATION OF CELL GROWTH CONTROL OF CHRONIC MYELOID LEUKEMIA PROGENITORS

M. Mancini[1,*], S. Soverini[1], S. De Santis[1], C. Monaldi[1], F. Castagnetti[1], L. Bavaro[1], M. Martelli[1], G. Gugliotta[1], G. Rosti[1], M.A. Santucci[1], M. Cavo[1], G. Martinelli[1]
[1]Istituto di Ematologia Seràgnoli-DIMES, Bologna, Italy

Background: Cell response to stress is a central component of genomic stability. The integrity of signaling pathways involved in cell cycle arrest, chromatin remodeling and DNA repair, are critical for the maintenance fidelity of replicated DNA. In this context, Gadd45 proteins function as stress sensors and gene transcription regulators. Gadd45a, in particular, intervenes in G2/M checkpoint induction and DNA repair, and it is required for efficient coordination of centrosome duplication hence preventing abnormal mitosis and aneuploidy. Such evidences let assume a putative role of Gadd45a in cancer development and progression. Interestingly, Gadd45a interacts with Aurora Kinase A (AK A), a key component of centrosome cycle and polar spindle assembly required for regulated progression from G2 tom and throughout M.
AK A is a member of a serine-threonine kinase family active during mitosis and it is frequently overexpressed in human cancers where correlates with a poor prognosis. Notably, AK A overexpression is always associated with defects in centrosome duplication, bipolar spindle and chromosomal segregation and aneuploidy, suggesting that it may enhance other oncogenic events by promoting genomic instability, one major trait of chronic myeloid leukemia (CML). Our results support the hypothesis that AK A cooperates with the constitutive TK activity of Bcr-Abl fusion protein by increasing DNA damage, promoting the occurrence of additional genomic alterations and driving TKIs resistance and disease progression to blast crisis.
Aims: Here we investigated AK A and Plk1 role in CML hematopoietic progenitor survival as potential targets to eradicate the transformed clone.
Methods: K562 cell line is a human cell line generated from a CML patient in blast crisis. Drug resistance was induced in K562 cell line by the exposure to progressively increasing doses of Imatinib (IM). It was validated by dose-response curves showing a significant difference in LD50 of IM-sensitive and IM–resistant cells. By mean of cytofluorimetric and immunofluorescence microscope analyses we investigated the events leading to AK/Plk1 deregulation. Protein expression and activation were detected by western blotting and immunoprecipitation. Apoptotic cell death was measured by using an Annexin V/PI staining; cell cycle distribution was observed by PI staining and subsequent cytofluorimetric analysis.
Results: Preliminary experiments were aimed to determine whether IM resistance in a BCR-ABL1 cell context is associated with the over-expression and hyper-activation of AKA/PLK1 axis. In our *in vitro* model drug resistance was associated with increased expression and phosphorylation of AK A (Y282) and Plk1 (T210). 24h exposure to IM significantly reduced expression and phosphorylation of both proteins in parental K562, but not in IM-resistant K562, indicating that AK A and Plk1 activation is only partly dependent on BCR-ABL1 TK activity. Subsequent experiments showed that the inhibition of AK A and PLK1 in response to specific inhibitors (Danusertib and Volasertib respectively) was associated with:
• significant increase of gadd45 a expression levels;
• reduction of cell survival;
• G2/M checkpoint arrest.
The findings support the role of AK A/PLK1 inhibition in restoration of signals involved cell growth control and apoptosis.
Summary/Conclusions: The advantage of using AK and Plk1 inhibitors in CML therapy mostly arises from effects independent from TK activity of Bcr-Abl protein. We proved that the AK and Plk1 inhibitors induce growth arrest and apoptosis in IM sensitive and resistant cell lines.

Lurie Comprehensive Cancer Center of Northwestern University, Chicago, [13]Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, United States, [14]University of Turin, Orbassano, Italy, [15]Novartis Pharma AG, Basel, Switzerland, [16]Novartis Pharmaceuticals Corporation, East Hanover, [17]Novartis Institute for Biomedical Research, Cambridge, United States, [18]Abteilung Hämatologie/Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: ENESTfreedom (NCT01784068) is evaluating the ability to stop NIL and remain in TFR in pts with a sustained deep molecular response (DMR) on frontline NIL. Previous results from ENESTfreedom showed that 51.6% of pts (98/190) who attempted TFR remained off treatment and in major MR (MMR; *BCR-ABL1* ≤ 0.1% on the International Scale [IS]) at 48 wk.
Aims: To analyze updated TFR data and predictive factors for remaining in TFR in ENESTfreedom.
Methods: Eligible pts had CML-CP with b2a2 and/or b3a2 *BCR-ABL1* transcripts, ≥2 y of frontline NIL, and $MR^{4.5}$ (*BCR-ABL1*^{IS} ≤0.0032%) prior to enrollment. All pts provided informed consent. After enrollment, pts continued NIL for 1 y (consolidation phase). MR was assessed every 12 wk during the 1-y consolidation phase; pts with no assessment worse than MR^4 (*BCR-ABL1*^{IS}≤0.01%), ≤2 assessments between MR^4 and $MR^{4.5}$, and $MR^{4.5}$ in the last assessment were eligible to enter TFR. Loss of MMR during TFR triggered reinitiation of NIL. To investigate potential predictors for remaining in TFR, pts were grouped according to Sokal risk score at diagnosis or depth of response prior to attempting TFR (based on response assessments in the consolidation phase), and 48-wk TFR rates in each subset were calculated. The current analysis was conducted when all pts who entered TFR had completed 96 wk of TFR, reinitiated NIL, or discontinued from the study (data cutoff, 31 Oct 2016).
Results: Of 190 pts who entered TFR, 93 (48.9% [95% CI, 41.6% - 56.3%]) remained in MMR and off treatment at wk 96, including 88 (46.3%) who were in $MR^{4.5}$. Three pts who were in TFR at 48 wk lost MMR by 96 wk, and 2 additional pts discontinued from the study between 48 and 96 wk without losing MMR. Among pts with low, intermediate, or high Sokal risk at diagnosis, 39/62 (62.9% [95% CI, 49.7% - 74.8%]), 25/50 (50.0% [95% CI, 35.5% - 64.5%]), and 9/28 (32.1% [95% CI, 15.9% - 52.4%]), respectively, remained in TFR at wk 48 (Sokal risk scores were missing for 50 pts). Among pts with $MR^{4.5}$ in all assessments during the consolidation phase, 90/170 (52.9% [95% CI, 45.2% - 60.6%]) remained in TFR at wk 48 *vs* 8/20 (40.0% [95% CI, 19.1% - 63.9%]) who had ≥1 assessment between MR^4 and $MR^{4.5}$ during the consolidation phase. Overall, of 88 pts who reinitiated NIL due to loss of MMR, 87 (98.9%) regained MMR and the remaining pt left the study 7.1 wk after NIL reinitiation without regaining MMR; 81 of 88 pts (92.0%) regained $MR^{4.5}$ by the data cutoff. Among pts remaining in TFR for >48 wk (n=100), adverse events (AEs) were less frequent during the second *vs* the first 48 wk of TFR; 2 (2.0%) and 1 (1.0%) of these pts had cardiovascular AEs during the first and second 48 wk of TFR, respectively; 34 (34.0%) and 9 (9.0%), respectively, had AEs in the predefined musculoskeletal pain grouping.
Summary/Conclusions: The majority of pts in TFR at 48 wk remained in TFR at 96 wk, and they reported fewer AEs during the second 48 wk of TFR than in the first 48 wk, affirming the durability and safety of TFR following NIL. No strong predictors for remaining in TFR were identified. Pts with low Sokal risk and pts with continuous $MR^{4.5}$ in the consolidation phase tended to have higher TFR rates than other pts, although these results must be interpreted with caution due to the small number of pts in some subsets and the wide 95% CIs. Additionally, the biological explanation for an association between Sokal risk score at diagnosis and a subsequent ability to remain in TFR is unknown. These results support TFR as a valuable option for pts in sustained DMR on frontline NIL.

P602

RESPONSE DIFFERENCES IN THE BCR-ABL1 E13A2 AND E14A2 VARIANTS MAY BE A TECHNICAL QPCR ARTIFACT

L. Kjaer[1,*], V. Skov[1], M. Gniot[2], L. Udby[1], M. Dorff[1], H. Hasselbalch[1], N. Pallisgaard[3]

[1]Department of Hematology, Zealand University Hospital, Roskilde, Roskilde, Denmark, [2]Department of Hematology, University of Medical Sciences, Poznan, Poland, [3]Department of Clinical Pathology, Zealand University Hospital, Roskilde, Roskilde, Denmark

Background: The t(9;22) translocation in chronic myeloid leukemia (CML) generally occurs in intron 12 or 13 of the BCR gene resulting in two different transcripts, the e13a2 or e14a2. It has been suggested that the two variants represent separate disease entities and that the transcript variants hold a prognostic value regarding treatment response, where e14a2 predicts a faster and deeper treatment response. However, no difference in overall survival has been observed and the issue remains controversial. Reverse transcription quantitative PCR (RT-qPCR) using the Europe Against Cancer (EAC) qPCR assay has been the gold standard for determining the levels of *BCR-ABL1* transcripts. The assay use common primers for amplification of the two variants resulting in a PCR product for the e14a2 variant that is 75 base pairs longer than the e13a2 variant. Under suboptimal PCR conditions, amplicons may be amplified with different efficiencies, which can result in an underestimation of especially the amount of longer qPCR products.
Aims: To study the accuracy of the EAC assay in quantifying the e13a2 and e14a2 transcripts.
Methods: Patient samples were screened for *BCR-ABL1* e13a2 and e14a2 transcript variants using either PCR with agarose gel separation or a droplet digital PCR (ddPCR) assay measuring the amount of e13a2 and e14a2 transcripts. The *BCR-ABL1* level was determined by qPCR using the QuantStudio instrument (Life Technologies) and expressed in the International Scale (%IS) using the EAC primers and assay conditions with *GUSB* and *BCR* as reference genes. Samples were re-measured by digital droplet PCR (ddPCR) on a QuantaLife instrument (Bio-Rad) using modified EAC primers multiplexed with *GUSB* and *BCR* as reference genes and expressed as %IS.
Results: Transcript levels from 124 *BCR-ABL1* positive patient samples were determined using the EAC qPCR assay (median: 0.08% IS, range: 0.001–159% IS) and ddPCR (median: 0.01% IS, range: 0.0002–124% IS). These included 59 samples with the e13a2 variant and 65 with the longer e14a2 variant. Comparing the expression levels obtained by the two techniques revealed ddPCR/qPCR ratio differences for e13a2 (median: 0.68, range: 0.35 - 3.2) and e14a2 (median: 3.43, range: 0–8.8), and a consistent 4.5 fold (>0.5 log) underestimation of the levels of the e14a2 compared to e13a2 when using qPCR (figure 1).

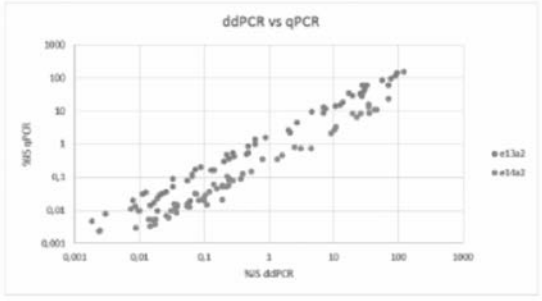

Figure 1. Scatter plot of %IS for 124 *BCR-ABL1* positive patient samples comparing values obtained by ddPCR (x-axis) and qPCR (y-axis). Samples with the e13a2 variant are shown in blue and samples with the e14a2 variant in orange. The plot clearly shows the underestimation of the longer transcript variant when using qPCR for quantification.

Figure 1.

Summary/Conclusions: When we compared the *BCR-ABL1* levels using qPCR and ddPCR, we observed a discrepancy between the e13a2 and e14a2 breakpoint variants. Since ddPCR is an endpoint measurement and not sensitive to variations in primer efficiencies, the most likely explanation for the discrepancy is a decreased qPCR efficiency of the longer e14a2 variant compared to e13a2 variant. Thus in qPCR analyses using the EAC protocol this may, at least on some analysis platforms, result in a consistently underestimation of the e14a2 level resulting in an appealingly better treatment response. A more than 0.5 log underestimation in a large subgroup of patients could have consequences in clinical decision-making *e.g.* by miss-grouping patients at different time points or when considering TKI discontinuation. Since many clinical laboratories uses the *BCR-ABL1* EAC protocol, the underestimation of the e14a2 variant could potentially be a widespread issue. We are presently working on an optimized *BCR-ABL1* qPCR protocol where the e14a2 underestimation is eliminated.

Background: Ponatinib is an oral tyrosine kinase inhibitor (TKI) approved for pts with CP-CML or Philadelphia chromosome–positive acute lymphoblastic leukemia (Ph+ ALL) for whom no other TKI therapy is indicated, or for pts with T315I. The ponatinib PACE trial (NCT01207440) enrolled pts with CML or Ph+ ALL resistant/intolerant to dasatinib or nilotinib, or with T315I. Long-term results in these heavily pretreated pts provide value in informing treatment decisions.
Aims: To report 5-yr efficacy and safety, and the association of early landmark responses with survival outcomes at 4 yrs past landmark, in heavily pretreated pts with CP-CML from PACE.
Methods: Ponatinib starting dose was 45mg/day. Dose reductions were instructed in Oct '13 to manage risk of arterial occlusive events (AOEs) observed with longer follow-up. Outcome measures were: 5-yr efficacy (n=267) and safety (n=270); post hoc landmark analysis (n=267) of the association of molecular responses (BCR-ABL^{IS} ≤0.1% [major molecular response (MMR)], >0.1–1%, >1%–10% and >10%) and cytogenetic responses (major [MCyR] and complete [CCyR]) at 3-, 6- and 12-mos with progression-free survival (PFS) and overall survival (OS) 4 yrs past landmark (log-rank *P* values). Data cutoff: 3 Oct '16.

Table 1.

Estimated PFS and OS at 4 yrs past landmark by BCR-ABL1 level

Landmark time	Response	n	PFS	*p–value	n	OS	*p–value
3 mo	BCR-ABL1						
	≤ 0.1%	32	97%	–	33	97%	–
	> 0.1–1%	47	57%	.32	48	85%	.54
	> 1%–10%	51	56%	.0050	55	80%	.10
	> 10%	82	51%	.0003	94	78%	.12
				overall: 0.0011			*overall: 0.27*
6 mo	BCR-ABL1						
	≤ 0.1%	57	83%	–	61	93%	–
	> 0.1–1%	42	53%	.011	44	83%	.021
	> 1%–10%	30	59%	.0004	32	90%	.18
	> 10%	57	50%	<.0001	74	78%	.0017
				overall: 0.0001			*overall: 0.0099*
12 mo	BCR-ABL1						
	≤ 0.1%	61	81%	–	63	97%	–
	> 0.1–1%	25	59%	.0086	27	85%	.014
	> 1%–10%	19	66%	.0092	22	95%	.058
	> 10%	41	52%	<.0001	50	80%	.0001
				overall: 0.0011			*overall: 0.0014*

*Calculated across the entire post-landmark timespan and unadjusted for multiple comparisons

Results: Baseline characteristics of the CP-CML pts included: median time from diagnosis, 7 yrs (range, 0.5–27 yrs); median age, 60 yrs (18–94 yrs); median %Ph+, 100% (2.5–100%); ≤10% Ph+, 20 pts (7%); 60% of CP-CML pts received ≥3 prior TKIs. At initiation of study closure, 99 pts (37%) were ongoing; among these pts, minimum follow-up was 52 mos, and most (78%) had 15mg/d as their last ponatinib dose. In efficacy-evaluable CP-CML pts, cumulative response rates as of the data cutoff were: MCyR, 60%; CCyR, 54%; MMR, 40%; and MR$^{4.5}$, 24%. Among pts who achieved MCyR (n=148) or MMR (n=108), the Kaplan-Meier (KM) estimated probability of remaining in response at 5 yrs was 74% (95% CI, 62–83) and 61% (95% CI, 51–70), respectively. Maintenance of response was high regardless of dose reductions in Oct '13. KM estimated 5-yr rates for PFS/OS were 49%/77%. Among pts with 3-, 6- and 12-mo landmark assessments, MCyR/CCyR was achieved in 48%/39%, 62%/52% and 71%/56%, respectively, and MMR achieved in 14%, 29% and 39%, respectively. Achievement of cytogenetic response and deep reductions in BCR-ABL1 levels (Table) at most landmark time points was associated with improved PFS and OS 4 yrs past landmark. Deeper responses at all landmarks were associated with achievement of MR$^{4.5}$ over time. Treatment-emergent adverse events (AEs) in ≥45% of CP-CML pts were rash 47%, abdominal pain 46%, and thrombocytopenia 46%. Most newly occurring AEs were observed within the first yr. The incidence of any AOE/serious AOE for CP-CML pts was

29%/23%. Among CP-CML pts with no prior AOEs who had a prospective dose reduction, 17% (11/63) had a first AOE occurring after Oct '13.
Summary/Conclusions: Long-term 5-yr results from PACE demonstrate that irrespective of dose reductions, ponatinib continues to show deep, lasting, clinically meaningful responses over time in heavily-pretreated pts with CP-CML. Achieving early cytogenetic response and deep reduction in BCR-ABL1 levels was associated with improved survival 4 yrs past landmark, demonstrating the prognostic value of early and deep response to ponatinib.

P604

LONG-TERM FOLLOW-UP IN VERY ELDERLY PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB FRONTLINE

Background: Very elderly (>75 yrs) people are a substantial proportion of chronic myeloid leukemia (CML) patients that sometimes receive Imatinib (IM) at reduced doses based on physicians' judgment. However, data on long-term follow-up of these patients are still lacking.
Aims: To investigate the treatment response and outcome in a cohort of very elderly patients with newly diagnosed CML in chronic phase.
Methods: We revised in a retrospective database 263 CML patients aged ≥ 75 years and diagnosed from 2/2002 to 1/2016 and treated with IM frontline; among these, 121 patients (46%) were older than 80 yrs.
Results: Median age at diagnosis was 78.5 yrs [interquartile range (IQR) [76.3–81.3]. Sokal Risk at diagnosis was low in 1 patient (0.4%), intermediate in 171 (68.4%), high in 78 (31.2%) and not evaluable in 13 patients. As regards comorbidities, 63 patients had no or 1 concomitant disease, 147 patients 2 or 3 and 53 patients (20.1%) 4 or more. Median interval from diagnosis to IM start was 0.8 month (IQR 0.3–1.6): the initial IM dose was 400mg/day in 180 (68.4%), 300mg/day in 67 (25.5%) and <300mg/day in 16 (6.1%) patients. According to WHO, grade 3-4 haematological and extra-haematological toxicities were reported in 57 (21,7%) and 51 (19.4%) patients, respectively. As regards cumulative response, 13 patients (4.9%) discontinued IM due to early toxicity, 4 (1.5%) were resistant and 2 (0.8%) died from unrelated causes early after IM initiation; 250 patients (92.8%) achieved a complete haematological response (CHR). Among these, 208 (79% of all 263 patients) achieved a cytogenetic response (CyR), which was partial in 18 patients and complete (CCyR) in 190 (72.2%) after a median period of 6.1 months since IM initiation (IQR 3.4-9.1). Among the 190 patients in CCyR, 148 (56.2%) achieved a molecular response (MMolR) (ratio < 0.1) after a median period time of 13.7 months (IQR 9.0-22.3). Eleven patients (4.2%) developed a blastic phase (myeloid in 8 and lymphoid in 3 cases). After a median follow-up of 45.0 months from IM start (IQR 22.3–72.0), 93 patients have died (9 from disease progression and 84 from unrelated causes), 144 are alive and 104 of them are still in treatment with IM, while 8 discontinued for prolonged deep molecular response and 22 switched to 2nd generation TKI. Five-years event-free survival (EFS) and overall survival (OS) were 51.2% (CI95% 44.8-57.6) and 70.9% (CI95% 64.6-77.2), respectively. At univariate analysis Hb level at diagnosis (≥ 12 *vs* ≤ 12g/dl, p=0.021) and the initial dose of IM (400 *vs* ≤300, p=0.048) were significant predictive factors for CCyR achievement, while PLT count at diagnosis (>500 *vs* < 500 x 10^9/l, p=0.006) and female gender (p=0.046) were significant predictive factors for MMolR achievement. Multivariate analysis for EFS and OS are described in Table1.

Table 1.

Multivariate analysis for EFS	OR	95% CI	P
400 mg IM initial dose	0.656	0.459 - 0.938	0,021
PLTS < 500 x 10^9/l	1.517	1.064 - 2.161	0.021
Concomitant diseases ≤ 3	0.597	0.398 - 0.896	0.013
Multivariate analysis for OS	**OR**	**95% CI**	**P**
MMolR achievement	0.363	0.236 - 0.560	<0,001
Age < 80 years	0.622	0.397 - 0.975	0.038
Male gender	1.589	1.048 - 2.410	0.029

Summary/Conclusions: The long term follow-up of very elderly CML patients treated with IM suggests that any effort to treat these patients with standard doses should be made, in order to achieve cytogenetic and molecular responses as in younger subjects.

P605

IMPACT OF ARTERIAL THROMBOTIC EVENTS ON THE LONG-TERM OUTCOME OF CHRONIC MYELOID LEUKEMIA (CML) PATIENTS TREATED IN FIRST-LINE WITH NILOTINIB: AN ANALYSIS OF THE GIMEMA CML WORKING PARTY

Maria delle Croci Hospital, Ravenna, [12]UOC of Hematology, San Giovanni - Addolorata Hospital, Rome, [13]Hematology Unit, Guglielmo da Saliceto Hospital, Piacenza, [14]Hematology Unit, "A.Businco" Hospital, Cagliari, [15]Hematology Unit, "Ospedali Riuniti" University Hospital, Ancona, [16]Department of Biochemistry and Medical Technologies, "Federico II" University, Naples, [17]University of Bologna, Bologna, Italy

Background: Nilotinib has shown better efficacy compared to imatinib, but it has been associated to a higher incidence of arterial thrombotic events (ATEs). Little is known on the impact of ATEs on the outcome of nilotinib treated patients.
Aims: To investigate the characteristics of ATEs and their impact on the long-term outcome of CML patients treated with nilotinib first-line.
Methods: We analyzed 345 patients ≥ 18 years of age with CP CML enrolled in clinical trials of the GIMEMA CML WP investigating nilotinib as first-line treatment. Patients were treated with: nilotinib 400mg BID (n=73); rotation of nilotinib 400mg BID / imatinib 400mg OD (3-month periods for each drug)(n=123); nilotinib 300mg BID (n=149). The median follow-up was 58 (22-82) months. The median age at CML diagnosis was 53 (18–86) years. We analyzed the rate, type, management, and outcome of ATEs; moreover, we compared the molecular response rates and the long-term outcome of patients with or without ATEs. Definitions: ATEs: peripheral arterial obstructive disease (PAOD), coronary syndromes, significant carotid stenosis and ischemic stroke, or other significant ischemic events; major molecular response (MMR): BCR-ABL ≤0.1% (IS), with >10.000 ABL copies; MR4: BCR-ABL≤0.01% (IS), with >10.000 ABL copies.
Results: Overall, 30/345 (8.7%) patients had ATEs during treatment with nilotinib. The median age at CML diagnosis of these patients was 64 (43-85) years, and the median age at ATEs was 67 (47-89) years. The median duration of nilotinib treatment at ATE was 25 (1-78) months. ATEs were: 14 coronary dis-

ease (including 7 acute myocardial infarction), 8 PAOD, 4 carotid stenosis (asymptomatic), 2 avascular necrosis of femoral head, 1 optic artery ischemia, 1 atherosclerosis of aorta/right iliac artery. Overall, 21 patients were hospitalized for the management of ATEs; 15 patients received medical treatment only, while the remaining required invasive interventions: 9 coronary angioplasty with stent positioning, 3 lower limbs amputations, 2 peripheral vascular bypasses, and 1 prosthesis of femoral head. No patient died for ATEs. Overall, 24 patients (80% of patients with ATEs, and 7% of the whole cohort) permanently discontinued nilotinib because of ATEs. The median follow-up after ATE was 15 (1–58) months. Of the 30 patients with ATEs, 26 (87%) achieved a MMR and 18 (60%) obtained a MR4, during nilotinib treatment. These rates were comparable to those observed in patients without ATEs (MR3: 260/315, 83%; MR4: 113/315, 64%). The 5-year progression-free survival and overall survival were similar in patients with or without ATEs (PFS: 96% *vs* 92%, p=0.55; OS: 96% *vs* 93%, p=0.79).

Summary/Conclusions: After a median follow-up of 58 months, 8.7% of patients treated front-line with nilotinib had ATEs, being coronary disease and PAOD the most common. ATEs were more frequent in elderly patients (median age at ATEs: 67 years). Half of the patients required invasive procedures, including major surgeries in 6 patients. The other patients were successfully managed with medical treatment. Importantly, no patients died for ATEs, and ATEs did not affect the rates of MMR, MR4 and 5-year PFS and OS, which were all comparable to those observed in patients without ATEs. Taken together, these data suggests that ATEs, despite being sometimes associated with significant morbidity, did not significantly impact on response rates and on long-term outcome of CML patients treated with nilotinib front-line.

P606

ASSESSMENT OF CHRONIC RENAL INJURY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN THE CHRONIC PHASE RECEIVING TYROSINE KINASE INHIBITORS

Q. Jiang[1,*], L. Zuo[2], X. Ren[1], X. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking University People's Hospital, Department of Nephrology, Beijing, China

Background: Long-term use of tyrosine kinase inhibitors (TKIs) may lead to chronic renal injury.

Aims: To evaluate the incidence of chronic kidney disease (CKD) in patients with chronic myeloid leukemia (CML) in the chronic phase (CP) receiving TKIs, and to identify the factors associated with the onset of CKD.

Methods: Data of CML-CP patients treated with TKIs as first-line or second- or third-line therapy for at least 3 months were analyzed. Glomerular filtration rate (GFR) was followed from the initiation of TKI-therapy. CKD was defined as persistent GFR less than 60 ml/min/1.73 m^2 or persistent more than 30% GFR reduction from baseline. CKD-free survival was used to evaluate the onset of CKD. Patients' characteristics and TKI used were analyzed to identify the factors associated with the onset of CKD by Cox regression model in those receiving first-line and second- or third-line TKI-therapy, respectively.

Results: 587 patients were included in this study. 383 (65%) were male. Median age was 40 (17-84) years.

464 patients received imatinib (n=363), nilotinib (n=88) or dasatinib (n=13) as first-line TKI-therapy. With a median follow-up of 35 months (range, 3-185 months), 136 of 416 (33%) patients with normal GFR at baseline developed CKD. Probabilities of CKD-free survival at 4 years were 62%, 78% and 100% in the patients receiving imatinib, nilotinib and dasatinib, respectively (p=0.004). Multivariate analysis showed that imatinib use (HR=2.4, 95% CI 1.4-4.3, p=0.002), male gender (HR=2.0, 95% CI 1.4-2.9, p=0.001), increasing age (HR=1.2, 95% CI 1.1-1.4, p=0.003) and prior administration of hydroxyurea, interferon or chemotherapy (HR=1.7, 95% CI 1.1-2.8, p=0.010) were factors associated with incident of CKD. In 48 patients with abnormal GFR or prior CKD before first-line TKI-therapy, 8 of 42 (19%) developed ≥30% GFR reduction from baseline during imatinib-therapy, while none of 6 during nilotinib- or dasatinib-therapy. In 123 patients receiving nilotinib (n=59) or dasatinib (n=64) as second- or third-line TKI-therapy after imatinib-failure, 13 of 110 (12%) with normal GFR at baseline developed CKD with a median follow-up of 19 months (range, 3-149 months). Probabilities of CKD-free survival at 3 years were 74% and 90% in those receiving nilotinib and dasatinib, respectively (p=0.059). Multivariate analysis showed that nilotinib use (HR=3.6, 95% CI 1.0-13, p=0.047) and a history of diabetes mellitus, hypertension or other renal diseases (HR=3.8, 95% CI 1.3~11.6, p=0.019) were factors associated with incident of CKD. 3 of 13 (23%) patients with abnormal GFR or prior CKD before second- or third-line TKI-therapy developed ≥30% GFR reduction from baseline during nilotinib (n=1) or dasatinib (n=2) therapy.

Summary/Conclusions: Our study showed that nilotinib and dasatinib were associated with less chronic renal injury compared with imatinib as first-line TKI-therapy, while dasatinib was related to less loss of renal function compared with nilotinib as second- or third-line TKI-therapy after imatinib-failure in CML-CP patients.

Background: Quantification of BCR-ABL1 transcript by qPCR is mandatory to monitor the response to TKIs therapy in CML patients. The achievement of Major or Deep Molecular Response (MMR or DMR) with TKIs is crucial for long-term survival and for treatment free remission (TFR). Currently, up to 30-40% of CML patients treated with TKIs can achieve DMR, but 50-60% of deep responders who discontinue the treatment loose their DMR and re-challenge continuous TKIs therapy. qPCR has some intrinsic limitations and it does not appear to be an optimal assay to select the best candidates to TKIs discontinuation. Digital PCR (dPCR) can give an absolute quantification of target nucleic acids by partitioning the PCR reaction mix over a large number of wells, each containing a single copy or no copies of the target region.

Aims: The aim was to comparatively monitor the BCR-ABL1 transcript levels by dPCR and qPCR in 57 CML patients treated with TKIs and achieving MMR or DMR in at least 3 time points.

Methods: Using qPCR and dPCR (QS3D Digital PCR System by Life Technologies), we comparatively analyzed 228 peripheral blood samples from 57 CML patients with MMR (n°14) or DMR (n°43). qPCR analysis were performed according to the last International Guidelines while absolute quantification of BCR-ABL1 transcript were obtained by dPCR and results were expressed as number of BCR-ABL1copies/ul of reaction. Patients were divided into 3 groups corresponding to the MR classes at the first time point: MR3.0, MR4.0 and MR4.5-5.0 groups. dPCR Positive Predictive Value (PPV) was also preliminary evaluated in 14 patients undergoing TKI discontinuation.

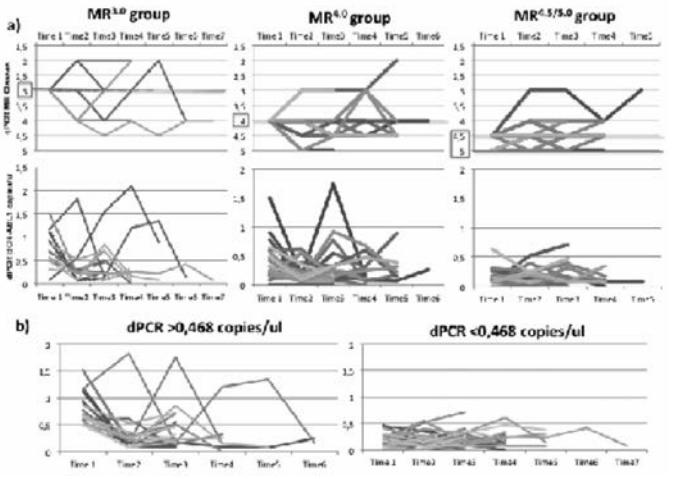

Figure 1.

Results: Analyzing comparatively the time course of MR in the patients of the three groups (MR3.0,MR4.0 and MR4.5-5.0) it was observed a similar trend, but the dPCR allowed to appreciate that, at the time of starting the monitoring the patients showed different levels of BCR-ABL1 copies/ml. Furthermore, those patients with MR4.5-5.0 undetectable by qPCR resulted with detectable BCR-ABL1 transcript levels when assessed by dPCR. Secondly, while MRD quantitations measured by qPCR appear to be more homogeneous, nearly due to a normalization effect of qPCR, the quantitations of MRD measured by dPCR appear to be more heterogeneous because of the high sensitivity and accuracy of dPCR. Therefore, dPCR values, reflecting the great heterogeneity of MRD level in patients belonging to the same MR group, suggest a higher accuracy in patients stratification (Figure 1a). dPCR value of 0,468 copies/ul, previously reported as value discriminating between major responders and deep responders, was used as threshold for dPCR data analysis. Patients with absolute value of BCR-ABL1 lower than 0,468copies/ul at the first time point presented more stable disease levels than the patients with absolute value of BCR-ABL1 higher than 0,468copies/ul (Figure 1b). In 14 CML patients who

discontinued TKIs, a preliminary analysis showed that 80% of patient with BCR-ABL1<0,468 copies/ul at discontinuation, maintained stable TFR (PPV of 80%).
Summary/Conclusions: This study suggests that dPCR is more precise and sensitive than qPCR when detecting levels of BCR-ABL1 transcript and that dPCR seems to be more robust and accurate for CML patients stratification. Larger and prospective studies are warranted to confirm the higher sensitivity and accuracy of dPCR and its usefulness to better select the candidates for TFR.

P608

OUTCOME OF BLAST PHASE CHRONIC MYELOID LEUKEMIA (CML-BP) IN THE TYROSINE KINASE INHIBITOR ERA

C. Talati[1,*], L. Isenalumhe[1], S. Shams[1], A. Kuykendall[1], J. Chavez[2], B. Shah[2], K. Sweet[2], J. Pinilla-Ibarz[2]
[1]Department of Malignant Hematology, University of South Florida/Moffitt Cancer Center, [2]Department of Malignant Hematology, Moffitt Cancer Center, Tampa, United States

Background: Primary goal of management in chronic myeloid leukemia (CML) is to prevent disease progression to blast phase CML (BP-CML). Current notion for management of BP-CML usually involves initiation of intensive chemotherapy regimen with addition of tyrosine kinase inhibitor (TKI). Despite treatment with intensive induction chemotherapy, outcome remains dismal.
Aims: We aimed to describe our experience with management of BP-CML and its outcome.
Methods: We included 58 patients from Moffitt Cancer Center from 2001 till 2016 with diagnosis of BP-CML and performed a retrospective chart review. Data elements including age, gender, peripheral blood and bone marrow parameters, phase of CML, treatment, cytogenetics and vital status were collected. Survival analysis using Kaplan-Meier method with log-rank test to determine significance by calculating two-sided p values was performed.

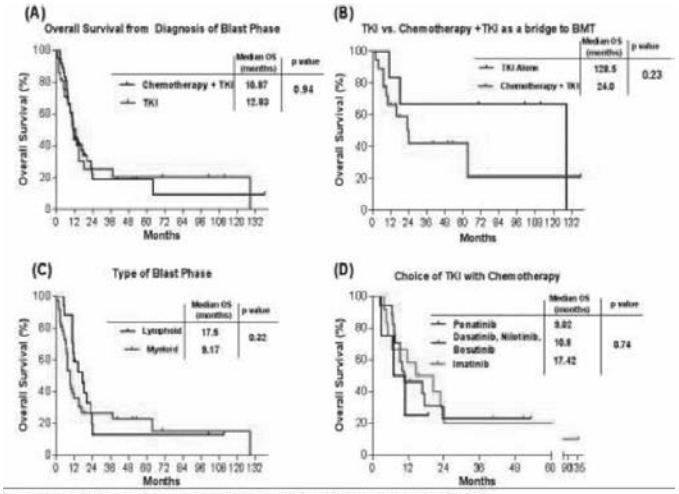

Figure 1: Overall survival in the era of TKI in management of Blast Phase CML.

Figure 1.

Results: The overall survival (OS) of our cohort was 31.87 months (mo). For patients with progression to BP-CML from previously known diagnosis of CML, median time to progression was 19.1 mo (range: 3.0-221.2 mo). The median OS from the diagnosis of BP-CML in this cohort was 10.8 mo, compared to *de novo* CML-BP cohort OS of 11.03 mo (p value=0.62). Myeloid blast phase CML had worse OS compared to lymphoid blast phase cohort but was not statistically significant (9.17 *vs* 17.5 mo, p=0.32). We further compared the treatment strategies of BP-CML including single agent TKI (n=21) and conventional chemotherapy regimens in combination with a TKI (n=36). The median OS of the cohort with single agent TKI was not statistically different from the combination with chemotherapy arm (12.83 mo *vs* 10.87 mo, p=0.73) as shown in Figure 1A. Additionally, combination of chemotherapy with TKI compared to single agent TKI did not have significant survival impact in either myeloid (9.17 *vs* 9.13 months, p=0.32) or lymphoid (14.47 *vs* 18.27 mo, p=0.24) BP-CML. Total of 26 patients (44.8%) proceeded to allogeneic bone marrow transplant, 26% (n=6) of which only received TKI prior to transplant compared to 76.9% (n=20) who received chemotherapy in combination with TKI. Use of single agent TKI rather than TKI in combination with chemotherapy prior to allogeneic transplant had a trend toward improved OS (128.5 *vs* 24 mo, p=0.23) (Fig 1B). Choice of TKI in combination with chemotherapy in treatment of BP-CML also did not identify any TKI combination resulting in superior survival (Figure 1D). Overall survival of the cohort stratified by presence of standard Philadelphia chromosome in comparison to additional cytogenetic aberrations did not detect difference in overall survival (10.87 *vs* 12.1 mo, p=0.51). Further evaluation of cytogenetic aberrations revealed monosomy 7 to be present in greater frequency in lymphoid blast phase compared to myeloid blast phase (35.71% *vs* 6.25%, p=0.02).
Summary/Conclusions: Our data suggest no survival difference when BP-CML is treated with a single agent TKI compared to a combination therapy, regardless of histology type. Therefore, single agent TKIs should be considered as an effective frontline therapy option for BP-CML, which may prevent the potential toxicity associated with chemotherapy. These findings need further validation in a larger prospective cohort.

P609

EFFICACY OF SWITCHING TO DASATINIB IN CHRONIC MYELOID PATIENTS WITH LATE WARNING RESPONSES TO IMATINIB. STUDY OF THE ASSOCIATION OF RESPONSE TO DASATINIB TO IMMUNOLOGIC STATUS

J.L. Steegmann[1,*], V. García-Gutiérrez[2], B. Colom[3], F. Sanchez-Guijo[4], R. Ayala[5], C. Boque[6], F. Casado[7], B. Xicoy[8], I. Montero[9], C. Soto[10], R. de Paz[11], A. Kreutzman[3], J. Martinez-Lopez[5], C. Muñoz[3]
[1]Servicio de Hematologia, Hospital Universitario de la Princesa/ IIS-IP Madrid, [2]Servicio de Hematologia, Hospital Universitario Ramón y Cajal, [3]Servicio de Inmunología, Hospital Universitario de la Princesa, Madrid, [4]Servicio de Hematologia, Hospital Universitario de Salamanca, Salamanca, [5]Servicio de Hematologia, Hospital Universitario 12 de Octubre, Madrid, [6]Servicio de Hematologia, Hospital Duran i Reynals., Barcelona, [7]Servicio de Hematologia, Hospital Virgen de la Salud, Toledo, [8]Servicio de Hematologia, Hospital Germans Trias i Pujol, Barcelona, [9]Servicio de Hematologia, Hospital Universitario Virgen del Rocio, Sevilla, [10]Servicio de Hematologia, Hospital Povisa, Vigo, [11]Servicio de Hematologia, Hospital Universitario La Paz, Madrid, Spain

Background: European LeukemiaNet (ELN) recommendations (2013) advised closely monitoring for patients with late warning response (patients with complete cytogenetic response without major molecular response after 12 months of treatment). Our trial, DASAPOST, has been the first one evaluating efficacy and safety of dasatinib in patients with late warning responses, and preliminary results have been reported (Garcia-Gutierrez et al, ASH 2016; P5450). Besides, many studies suggest that dasatinib may augment responses due to its immunomodulating effect. Although NK and CD8 cells seem to be involved, the specific mechanism remains to be clarified.
Aims: To evaluate the efficacy and safety of switching change to dasatinib in patients treated with imatinib first line during at least 18 months and having a late warning response, and to study the association between response to dasatinib and immune robustness, both baseline and during the therapy, and dasatinib-induced lymphocyte "mobilization".
Methods: Phase II, open, multicenter DASAPOST study (NCT01802450). Patients previously treated with imatinib after at least 18 months, with CCyR but without MMR, were included. All BCR-ABL/ABL (IS) measurements were centralized in a EUTOS laboratory. Patients not molecularly analyzed at a given time point were considered as non responders, Lymphocyte counts, subpopulations and migration studies were done at baseline (1st day of dasatinib), and every 3 months, and they were done both previous to the dose, and 2 hours after.

Table 1.

	Lymphocytes Baseline	CD8 Baseline	CD4 Baseline	NK Baseline
N (x 10^9/L)	1.78(0.83-3.24)	0.4(0.15-1.43)	0.68(0.43-1.59)	0,20(0.05-0.77)
Percentage	27.4(14.5-39.2)	32,2(15.4-64.8)	65.4(30.4-82.8)	14.1(2.9-40.3)

Results: From April 2013 to May 2015, 18 patients were enrolled in 12 centers. Median age was 59 years (39-77). The ratio of men to women was 13/5, and the Sokal risk groups were 48%, 30% and 22% for low, intermediate and high risk, respectively. Median time from diagnosis to switch to dasatinib was 2.6 years (1.6-23) and median time while on imatinib to achieve CCyR 1.4 years (0.2-12). Median exposure to imatinib was 2.4 years (1.6-14). Eight patients (44.4%) obtained MMR at 3 months, and 12 (66.7%) obtained MMR at 6 and 12 months. Of interest 9/18 patients (50%) achieved MR4 by 12 months. There were 3 study discontinuations because of toxicity (16%). Table 1 shows the median number of the most relevant lymphocyte populations in the pre-dose sample at baseline. Table 2 shows that the absolute number of CD8 cells was significantly superior at baseline in those patients having a MMR at 3 months, with a trend in the same direction of absolute lymphocyte count and percentage. There were no significant associations with response when considering CD4 T cells, NK cells, or the degree of mobilization after dasatinib dose either in total lymphocyte numbers or in subpopulations. Besides, lymphocyte number or proportions at 3 or 6 months were not associated with MMR at 6 or 12 months (data not shown).

Table 2.

	MMR 3m	No MMR 3m	p
Lymphocytes Baseline (x 10^9/L)	2.23	1.63	0.051
Lymphocytes Baseline (%)	30.4	23.3	0.053
CD8 Baseline (x 10^9/L)	0.62	0,29	0.037
CD8 3 monthd (x 10^9/L)	0,72	0,49	0.088

Summary/Conclusions: Our study shows that in patients treated with imatinib and with late warning responses, switching to Dasatinib induced MMR in 2 out every 3 patients, and MR4 in half of the patients, with a good safety profile. Contrarily to other group reports, we have not found any significant association between response and lymphocyte mobilization in any point studied. Interestingly, the absolute number of CD8 at baseline was significantly associated with the early obtention of MMR at 3 months, a finding which underscore the prognostic importance of baseline immune status, the relevance of CD8 cells in the antileukemic effect,and which suggest that this quite simple variable must be included in future studies with dasatinib in second line.

P610

GENETIC PREDICTION OF INSULIN RESISTANCE IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH NILOTINIB

G. Caocci[1,*], C. Mammì[2], C. Labate[2], S. Rodi[2], D. Ielo[3], M. Priolo[2], M. Postorino[4], G. Tripepi[5], F. Ronco[3], C. Laganà[2], B. Martino[3]
[1]Hematology, Department of Medical Sciences, University of Cagliari, Cagliari, [2]Operative Unit of Medical Genetics, [3]Operative Unit of Hematology, [4]Operative Unit of Nephrology, Grande Ospedale Metropolitano "Bianchi-Melacrino-Morelli", [5]Epidemiology Research Unit, CNR-IBIM, Reggio Calabria, Italy

Background: Impaired fasting glucose (IFG) and type 2 diabetes (T2D) represents adverse events in Chronic Myeloid Leukemia (CML) patients treated with the second-generation tyrosine kinase inhibitor (TKI) nilotinib. A genetic risk score (uGRS) for the prediction of insulin resistance, consisting of 10 multiple single-nucleotide polymorphisms (SNPs), has been proposed.
Aims: We evaluated the uGRS predictivity in 45 CML patients treated with nilotinib.
Methods: Patients were genotyped for IRS1, GRB14, ARL15, PPARG, PEPD, ANKRD55/MAP3K1, PDGFC, LYPLAL1, RSPO3, and FAM13A1 genes. The uGRS was based on the sum of the risk alleles within the set of selected SNPs.
Results: $MR^{3.0}$ and CMR were achieved in 91% and 84% of the patients, respectively.Before treatment, none of the patients had abnormal blood glucose. During treatment and subsequently follow-up of 84.4 months (range 1-298), 5 patients (11%) developed diabetes requiring oral treatment, after a median of 11 months (range 3-95) since nilotinib. Nine patients (20%) developed prediabetes. Prediabetes/diabetes-free survival was significantly higher in patients with an uGRS below 10 compared to higher scores (100% *vs* 18%, p=0.004) (Figure). Each increment of 1 unit on the uGRS caused a 42% increase in the prediabetes/diabetes risk (HR=1.42; CI: 1.04-1.94; p=0.026).

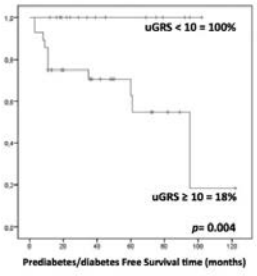

Figure 1.

Summary/Conclusions: Although nilotinib is not associated with a higher incidence of TD2 compared to a general population, it could be an early "highlighter" of genetic predisposition to the disorder. The presence of more than 10 allelic variants associated to insulin secretion, processing, sensitivity and clearance is predictive of prediabetes/diabetes developing. In clinical practice uGRS could help tailor the best TKI therapy.

P611

THE EUROPE AGAINST CANCER PROTOCOL FOR BCR-ABL P210 TRANSCRIPT MEASUREMENT MAY OVERESTIMATE RESULTS FOR E13A2 VARIANT

M. Gniot[1,*], M. Komarnicki[1], K. Lewandowski[1]
[1]Hematology, Poznan University of Medical Sciences, Poznań, Poland

Background: The quantitative PCR of *BCR-ABL* transcript has been the most useful technique for monitoring therapy in CML patients for over a decade. The numerous standardization projects have been undertaken in order to harmonize the molecular response results in laboratories all over the world. However, our data suggest that using the most common protocol may lead to overestimation of e13a2 transcript.
Aims: The goal of the study was to verify the observation that e14a2 transcript amplifies less efficiently than e13a2. The secondary goal was to validate the modification of Europe Against Cancer (EAC) protocol developed in 2011 which corrects observed artifacts.
Methods: The *BCR-ABL* measurements acquired using EAC and in-house modified EAC protocol have been compared with results from SA Pathology in Adelaide. The Adelaide protocol (Branford and Hughes 2006) consists of separate, optimized reactions for e13a2 and 14a2 transcripts, therefore it should be considered free of any PCR efficiency-related artifacts. The data originated from four independent sample batches exchanged between Poznan and Adelaide since 2009.
Results: The analysis of retrospective EAC protocol data showed that when e13a2 and e14a2 samples entered the exponential phase at the same time, the latter would cross the threshold approximately 2.2 cycles after the first one. Re-analysis of data from sample exchanges from 2009 revealed that after establishing a conversion factor (CF), all of the e14a2 measurements in Poznan were underestimated according to Adelaide. At the same time, almost all of e13a2 samples were overestimated (fig. 1). Still, the bias between methods was acceptable and a valid conversion factor (CF) was calculated. The method modification introduced 2011 eliminated this difference and increased concordance between laboratories. The last sample batch revealed significant difference between non-modified and modified EAC protocols in e13a2 measurements: 4,56 (+/- 0.96). Reanalysis of sample batch from 2009 (presented on fig.1) using 4.57 (2x2.28) factor (e13a2 results divided by 2.28, e14a2 results multiplied by 2.28) resulted in almost perfect data alignment. The results of modified EAC protocol, after CF recalculation, showed very good concordance with Adelaide (100% results of e14a2 and 88% of e13a2 within 2-fold of reference laboratory).

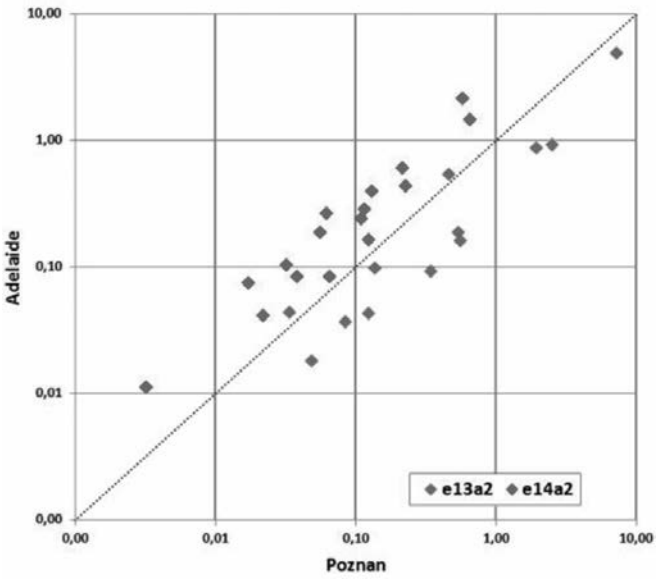

Figure 1.

Summary/Conclusions: In the EAC protocol, the e14a2 transcript amplifies less efficiently than e13a2. Since commonly used plasmids, including ERM-AD623, are based on e14a2, the standard curve is being shifted towards the latter cycles. It leads to overestimation of e13a2 by mean factor of 4.5 (over 0.5 log), which could be clinically significant. The reports of worse outcome of e13a2 patients are probably caused by this artifact, which can be easily eliminated by implementing an additional forward primer to EAC protocol. This overestimation cannot be detected in case of lab to lab validation when two centers are using EAC protocol. In case of method validation in Adelaide, those differences were not as obvious as well. The shift of 4.5 (fig. 1) means that results are 2.25 times different from the perfect concordance line and could easily fit into accepted 2-fold and 3-fold compartments. The CF calculated by Adelaide would depend on the percentage of each transcripts among the exchanged samples. The observed artifact should be also taken into consideration in clinical trials that rely on surrogate endpoints such as molecular response level at certain time points. Uneven transcript variant distribution between compared groups may lead to improper conclusions.

Enzymes and sickle cell disease

P612

ESTABLISHMENT OF IN VIVO AND IN VITRO MODEL OF X-LINKED SIDEROBLASTIC ANEMIA

K. Saito[1,*], T. Fujiwara[1], M. Morita[2], Y. Okitsu[1], N. Fukuhara[1], Y. Onishi[1], Y. Nakamura[3], R. Shimizu[4], H. Harigae[1]
[1]Hematology and Rheumatology, [2]Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, [3]Cell Engineering Division, RIKEN BioResource Center, Tsukuba, [4]Molecular Hematology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Congenital sideroblastic anemia (CSA) is an inherited microcytic anemia characterized by the presence of bone marrow ring sideroblasts, reflecting excess mitochondrial iron deposition. The most common form of CSA is X-linked sideroblastic anemia (XLSA), which is attributed to mutations in the X-linked gene erythroid-specific 5-aminolevulinate synthase (*ALAS2)*. *ALAS2* resides on chromosome X and encodes the enzyme that catalyzes the first and rate-limiting steps in the heme biosynthesis pathway in erythroid cells. This pathway converts glycine and acetyl-coenzyme A to 5-aminolevulinic acid (ALA), which requires pyridoxal 5'-phosphate (PLP) as a cofactor. Although PLP has been used for treating XLSA, a marked proportion of patients with XLSA remain refractory to treatment (Ohba *et al.* Ann Hematol 2013). Thus, there is a need to establish a model of XLSA to reveal the detailed molecular mechanism contributing to RS formation as well as to explore novel therapeutic strategy for XLSA.
Aims: We explored to establish a novel model of XLSA by CRISPR/Cas9-based genome editing.
Methods: We targeted the GATA-1-binding region of intron 1 of the human *ALAS2* gene based on both *in vivo* mice and human induced pluripotent stem cell-derived erythroid progenitor (HiDEP) cells (Kurita *et al*. PLoS One 2013). The mutation diminished the binding of transcription factor GATA-1, which would lead to decreased transcription of the *ALAS2* gene, thereby causing XLSA (Kaneko *et al*. Haematologica 2014). Western blotting and quantitative chromatin immunoprecipitation (ChIP) analysis were performed using antibodies against GATA-1 (D52H6, Cell Signaling Technologies) and TAL1 (C-21, Santa Cruz). For transcription profiling, Human Oligo chip 25K (Toray) was used. Gene ontology (GO) analysis was performed with Genecoids (http://genecodis2.dacya.ucm.es/).
Results: We first generated a founder female mouse lacking the intron 1 enhancer region of *Alas2*, including the GATA binding domain (*Alas2*$^{\Delta int1/X}$). Whereas the heterozygous *Alas2*$^{\Delta int1/X}$ mice were viable and did not show anemic phenotype, hemizygous deletion (*Alas2*$^{\Delta int1/Y}$) in male mice led to an embryonic lethality, suggesting that this sequence is indispensable in the context of mice. As an alternate approach, we established a clonal line with HiDEP cells, which harbored 19-bp deletion within the intron 1 enhancer region of *ALAS2*, including GATA binding domain. Whereas wild-type HiDEP cells exhibited red color, the XLSA clone appeared pink/pale color, which were accompanied by the significantly decreased intracellular heme concentration. Despite no obvious change in the expression of GATA-1 protein in the XLSA clone, quantitative ChIP analysis demonstrated that the chromatin occupancies of GATA-1 and its cofactor TAL1 were significantly abrogated by the deletion of the GATA binding motif at intron 1 enhancer of the *ALAS2* gene. Quantitative real-time–polymerase chain reaction (RT–PCR) analysis demonstrated significant downregulation of *ALAS2* as well as globin genes (*HBA*, *HBG*, and *HBB*) in the XLSA clone. Microarray analysis revealed >2-fold up- and down-regulation of 619 and 274 genes caused by the 19-bp deletion, respectively. The downregulated gene ensemble included globins (*HBZ*, *HBG*, *HBE*, *HBD*, *HBM*, and *HBQ*) as well as genes involved in iron/heme metabolism (*ALAS2*, transferrin receptor: *TFRC*, coproporphyrinogen oxidase: *CPOX*, and mitoferrin 1: *MFRN1*). GO analysis revealed significant enrichment of cellular iron ion homeostasis (p=0.018), regulation of transcription (p=0.0021), and innate immune response (p=0.0018), implying that heme was involved in various biological processes in erythroid cells. Interestingly, ALA treatment significantly improved compromised heme production as well as downregulation of globin genes observed in the XLSA clone, suggesting that ALA may represent a novel therapeutic option for PLP-refractory XLSA.
Summary/Conclusions: The XLSA model established from HiDEP cells can be used as an important tool for clarifying the molecular etiology of XLSA and to explore novel therapeutic strategies.

P613

BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY FOR COLD AGGLUTININ DISEASE: RESULTS OF A PROSPECTIVE NORDIC TRIAL

S. Berentsen[1,*], U. Randen[2], M. Oksman[3], H. Birgens[4], T.H.A. Tvedt[5], J. Dalgaard[6], E. Galteland[7], E. Haukås[8], A.M. Malecka[2], G.E. Tjønnfjord[9]
[1]Department of Research and Innovation, HAUGESUND HOSPITAL, Haugesund, [2]Department of Pathology, Oslo University Hospital, Oslo, Norway, [3]Department of Hematology and Stem Cell Transplantation, Turku University Hospital, Turku, Finland, [4]Department of Haematology, Herlev Hospital, University of Copenhagen, Herlev, Denmark, [5]Department of Mesdicine, Haukeland University Hospital, Bergen, [6]Medical Department, Drammen Hospital, Vestre Viken Trust, Drammen, [7]Department of Medicine, Akershus University Hospital, Nordbyhagen, [8]Department of Hematology and Oncology, Stavanger University Hospital, Stavanger, [9]Department of Hematology, Oslo University Hospital, Oslo, Norway

Background: Primary cold agglutinin disease (CAD) is an autoimmune hemolytic anemia in which a well-defined clonal lymphoproliferative bone marrow disorder (LPD) causes production of monoclonal cold agglutinins. Major clinical manifestations are anemia and, in most cases, cold-induced circulatory symptoms. Pharmacological therapy, although not indicated in patients with very mild disease, seems required in a majority of cases. Corticosteroids are ineffective. Rituximab monotherapy has resulted in approximately 50% response rate and 1-year median response duration. Fludarabine and rituximab combination therapy showed 70% response rate (20% complete responses) and very long response duration, but considerable toxicity.
Aims: We wanted to investigate whether bendamustine and rituximab combination therapy can result in favorable response rates and duration with an acceptable toxicity profile.
Methods: We conducted a prospective, uncontrolled multicenter trial with 16 participating hospitals from Norway, Finland and Denmark. Essential inclusion criteria were verified CAD with symptomatic anemia and/or severe cold-induced circulatory symptoms. Eligible patients received 4 cycles of rituximab 375mg/m^2 day 1 and bendamustine 90mg/m^2 day 1-2 with 28 days interval. Outcomes were classified into complete response (CR), partial responses (PR) and non-response (NR). The definition of CR included normalization of hemoglobin (Hb) levels with no hemolysis, complete histologic resolution of the bone marrow LPD and disappearance of monoclonal serum protein. The criteria for PR included increase in Hb levels by at least 2.0 g/dL or to the normal range, transfusion independence, at least 50% reduction of IgM and improvement of any circulatory symptoms.
Results: Forty-four patients (19 men and 25 women) were included, with a median age of 74 years (range, 48-86) and median disease duration 4 years (range, 0-18). Seventeen patients had received previous therapy. At baseline, median Hb level was 9.5g/dL (range, 4.5-14.8), bilirubin 45micromol/L, lactate dehydrogense (LDH) 468 U/L, haptoglobin undetectable, IgM 4.1g/L (1.0-27.2), CA titer 2048 (64-65536). Monoclonal IgM kappa was detected in 38 patients, IgG kappa in 1 and IgA kappa in 1. We observed CR in 16 patients (36%), PR in 15 (34%), while the remaining 13 (30%) were non-responders. Hb levels increased by a median of 4.0g/dL in the responders; 4.4g/dL in patients achieving CR and 3.9g/dL in those achieving PR. Median post-therapy Hb levels were 14.2g/dL (CR), 12.5g/dL (PR) and 10.5g/dL (NR). Acrocyanosis and Raynaud symptoms resolved completely in 16 patients and improved in 11 (47% and 32%, respectively, of those with such symptoms at baseline). Histologic regression of the LPD was complete in 17 patients (39%), partial in 5 (11%) and not evaluable in 18 (41%). Median time to response was 2 months (0.5-12). Only 3 responders experienced relapse; 2 after PR and 1 after CR. Median observed response duration was 32 months (range, 1-62) during median 32 months follow-up from response, consistent with a much longer expected response duration. Neutropenia grade >3 occurred in 14 patients (32%), of which 8 (18%) had grade 4. Three patients (7%) experienced 1-3 episodes of febrile neutropenia, which was readily manageable. Non-hematologic toxicity occurred in 17 patients (39%), mostly consisting of mild nausea or rash. Three non-neutropenic serious adverse events (SAE) were recorded; 1 was considered probably therapy related.
Summary/Conclusions: Bendamustine and rituximab combination therapy resulted in high response rates, a high rate of CR, long response duration and few relapses during the observation period, with a favorable safety profile. It might be considered in the first line for reasonably fit patients with CAD requiring therapy.

P614

EX VIVO TREATMENT OF RED BLOOD CELLS FROM 15 PYRUVATE KINASE (PK)-DEFICIENT PATIENTS WITH AG-348, AN ALLOSTERIC ACTIVATOR OF PK-R, INCREASES ENZYMATIC ACTIVITY, PROTEIN STABILITY AND ATP LEVELS.

B. van Oirschot[1], P.A. Kosinski[2], J. Hixon[3], K. Johnson[2], V. Chubukov[2], L. Dang[2], G. Pasterkamp[1], S. van Straaten[14], C. Kung[2], R. van Wijk[1,*]
[1]Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Agios Pharmaceuticals, Inc., [3]KSQ Therapeutics, Cambridge, MA, United States, [4]Van Creveldkliniek, University Medical Center Utrecht, Utrecht, Netherlands

Background: Pyruvate kinase (PK) deficiency is a rare hereditary disorder affecting red blood cell (RBC) glycolysis. It is caused by mutations in the *PKLR* gene. PK-deficient RBCs are characterized by changes in metabolism associated with defective glycolysis, including a build-up of the upstream metabolite 2,3-disphosphoglycerate, and deficiency in the PK product ATP. It is hypothesized that insufficient energy production affects red cell homeostasis, promoting

premature removal of PK-deficient RBCs from the circulation. Affected patients display chronic hemolytic anemia of variable severity. Treatment of PK-deficient patients is generally supportive, focusing on the anemia and iron overload state, and there are no approved drugs that directly target mutated PK. AG-348 is an allosteric activator of the RBC isoform of PK (PK-R) and in clinical development for the treatment of PK deficiency

Aims: To evaluate the *ex vivo* effect of AG-348 treatment on PK-R enzymatic function, RBC metabolism and deformability

Methods: Observational case-control study, approved by the Institutional Review Board. All patients gave informed consent. Enrolled patients (N=15) were adults, transfusion-independent and compound heterozygous or homozygous for mutations in *PKLR*. Baseline metabolic profiling was performed by LC-MS/MS. Purified RBCs from patients and healthy control subjects were incubated with AG-348 (up to 10 µM) for 24 hours at 37°C. After 6 and 24 hours PK-R activity, ATP levels and RBC deformability (by Lorrca) were measured. For determination of PK-R thermal stability, RBC lysates were incubated for 2 hours with 2 µM AG-348 (37°C) prior to testing. Baseline protein levels of PK-R were assessed using antibodies against PK-R

Results: Baseline patient characteristics show strongly reduced PK-R activity in all patient cells, in particular taking into account the degree of reticulocytosis (Table 1). Distinct metabolic changes were consistent with a block of glycolysis at the PK-R step. Treatment of PK-deficient RBCs with AG-348 resulted in increased enzymatic activity in all patient cells after 24 hours (mean increase 1.8-fold, range, 1.2-3.4). Similar increases were observed in control cells (mean fold increase 2.3, range, 1.2-7.1). ATP levels in PK-deficient cells increased upon AG-348 treatment (mean increase 1.5-fold, range: 1.0-2.2) similar to control cells (mean increase 1.6 fold, range, 1.4-1.8). Generally, PK-R thermal stability was strongly reduced in PK-deficient patient cells, illustrated by a mean loss of activity of 72% (19% for control cells) after incubation at 53 °C for 60 minutes. *Ex vivo* treatment with AG-348 prior to incubation resulted in residual activity 1.4 to >10-fold higher than residual activity of vehicle-treated samples. Baseline protein level analyses suggests that a certain level of PK-R protein is required for cells to respond to AG-348 treatment *ex-vivo*, as treatment effects were minimal in patient cells with very low or undetectable levels of PK-R. In approximately half of the patients, *ex vivo* treatment with AG-348 was associated with an increase in RBC deformability, although there doesn't appear to be a clear correlation with enzymatic or metabolic response.

Table 1.

Table 1. Baseline characteristics and genotypes of PK-deficient patients

AG060/M	c.1529G>A/c.1529G>A	R510Q/R510Q	12.8	40	1.6	2.8	0.6
		Reference	M: 13.8-17.2 F: 11.9-15.5	1-2	9.2-16.9	0.9-1.4	9.0-16.6

Summary/Conclusions: These data support the hypothesis that drug intervention with AG-348 effectively upregulates PK-R enzymatic activity and increases stability in PK-deficient RBCs over a broad range of *PKLR* genotypes. The concomitant increase in ATP levels suggests that glycolytic pathway activity may be restored. AG-348 treatment may represent an attractive way to correct the underlying pathologies of PK deficiency

P615

IDENTIFICATION OF NEW PATHOGENIC MUTATIONS IN PATIENTS WITH RED BLOOD CELL MEMBRANE DISORDERS USING NEXT-GENERATION SEQUENCING

M.D.M. Mañu Pereira[1,*], E. LLaudet Planas[1], V. Rizzuto[1], J. L. Vives Corrons[1]
[1]Red Blood Cell Pathology And Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: Red blood cell (RBC) membrane proteins deficiency or structural alterations lead to RBC membrane disorders such as hereditary spherocytosis, hereditary elliptocytosis or hereditary xerocytosis among others. Genetic analysis of these patients was not usually performed before next-generation sequencing due to the laborious task it consisted to sequence by Sanger the several membrane related genes, considering that they all contain a high number of coding regions.

Aims: The aim of this study is to perform the molecular diagnosis of the patients included in the study as well as to identify new pathogenic mutations leading to RBC membrane disorders.

Methods: 116 patients from 74 unrelated families were studied with a next generation sequencing (NGS) based panel that contained genes already described as disease causing for RBC membrane disorders (ANK1, EPB41, EPB42, SLC4A1, SPTA1, SPTB, PIEZO1, KCNN4, RHAG) as well as for enzymopathies (ADA, AK1, ALDOA, BPGM, CYB5A, G6PD, GCLC, GPI, GSR, GSS, HK1, NT5C3A, PFKM, PGK1, PKLR, TPI1), hemoglobinopathies (HBA1, HBA2, HBB) and congenital diseritrhopoietic anaemias (CDAN1, C15orf41, SEC23B, KLF1, GATA1, KIF23). The patients analysed were oriented as hereditary spherocytosis (63 patients), hereditary elliptocytosis or piropoikilocytosis (8 patients) and hereditary xerocytosis (3 patients). There were also 42 patients were the combination of phenotypic laboratory results was suggestive of membranopathy but it didn't suggest any specific RBC membrane pathology.

Results: A total of 74 pathogenic variants leading to RBC membrane disorders were identified, of which 14 had already been reported as disease causing. Of the remaining 60 variants, 42 had never been identified neither by 1000G or ExAC projects and therefore are novel mutations. Beta-spectrin, ankyrin and alpha-spectrin were the proteins that gathered most part of the mutations, we identified 23 variants in SPTB, 20 variants in ANK1 and 16 variants in SPTA. 48% (36/74) of the identified variants were missense changes, mostly from SPTB gene (11 variants), while a 38% (28/74) of the variants were nonsense changes or frame shifting mutations, mostly from ANK1 (12 variants) and SPTB (9 variants). Of special interest, only 2 variants were identified in more than one unrelated family: 1) SPTB c.647G>A, leading to spherocytosis, was identified in 8 patients of 2 unrelated families, 2) SPTA1 c460_462dupTTG, leading to ellyptocytosis, was identified in 6 patients from 5 different unrelated families. Finally, with the NGS panel results, the genetic diagnosis of 89% (103/116) of the included patients could be determined and only in 11% (13/116) the mutation was not identified or the variant correlation with disease was not clear. It is worthy to highlight that 10 of the 13 undiagnosed patients had been oriented as unclear membranopathy.

Summary/Conclusions: According to the results, there is a high genetic heterogeneity in patients with RBC membrane disorders, as almost each family carries a unique mutation that is not observed in any other no related family. The present study reveals the usefulness of NGS panel, which allows the molecular diagnosis of almost the 90% of the patients and it would avoid misdiagnosis that could lead to splenectomy in contraindicated cases such as in hereditary xerocytosis. Moreover, the 11% of undiagnosed patients will be analyzed through a second NGS gene panel including potential new genes leading to chronic haemolysis and/or sequenced by whole exome sequencing with the aim to identify new disease causing genes.

Eugenio, Roma, Roma, [8]Hematology, Azienda Ospedaliera Niguarda Ca' Granda - Milano, Milano, [9]Hematology, Università degli Studi di Napoli Federico II, Napoli, [10]Epidemiology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Milano, [11]Ematologia, Spedali Civili di Brescia, Brescia, [12]Hematology, Dipartimento di Medicina Traslazionale, Università del Piemonte Orientale Amedeo Avogadro, Novara, Novara, [13]Hematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Milano, Italy

Background: Autoimmune hemolytic anemia (AIHA) is greatly heterogeneous, from mild/compensated to life-threatening, due to autoantibody class/thermal amplitude, efficiency in activating complement, activity of the reticuloendothelial system, and efficacy of bone marrow compensatory response.

Aims: Here we analysed predictors of first relapse, complications, and fatality in a large AIHA series.

Methods: We retrospectively studied 378 patients (135m and 243 F, median age 61 yrs, range 19-100) from 10 sites, followed-up for 4.3 yrs (range 0.5-27). Patients were classified in warm (w)AIHA (DAT positive for IgG and IgG+C), cold agglutinin disease, CAD (C), mixed (IgG+C with high titer cold agglutinins) and atypical (DAT-, IgA+, wIgM). Cases were also grouped in very severe (Hb<6 g/dl), severe (Hb 6-8 g/dl), moderate (Hb 8-10 g/dl) and mild (Hb>10 g/dl). LDH was expressed as fold increase upper the limit of normality (ULN), and reticulocytes as absolute count and reticulocyte index. The following therapy lines were considered a) steroids +/-IvIg, b) rituximab c) splenectomy, d) immunosuppressive drugs (azathioprine, cyclophosphamyde, cyclosporin), and e) transfusions, plasma exchange, erythropoietin.

Results: Table 1 shows clinical and laboratory characteristics of AIHA cases at onset and distribution of thermal types. Hb values were significantly lower in IgG+C wAIHA and atypical cases (p<0.001), LDH higher in IgG+C wAIHA, mixed and atypical forms (p=0.01), and Hb and LDH values were negatively correlated (r= -0.25, p<0.001). Absolute reticulocytes were reduced in CAD, mixed and IgG+C wAIHA (p<0.001) together with inadequate reticulocytosis (p=0.01). Moreover, the reticulocyte index was lower in cases with Hb<6 g/dL (65 *vs* 98, p<0.001), along with more frequent inadequate reticulocytosis (87 *vs* 70%, p=0.01). First line therapy was administered in almost all cases but 25 CAD. A second therapy line was mostly required in IgG+C wAIHA, mixed, and to a lesser extent in CAD (p=0.005). The ultra-refractory cases requiring 4 or more lines of therapy were mainly mixed, atypical and CAD. Considering anemia severity, patients with Hb<8 g/dL more frequently required treatment after first-line (51 *vs* 33%, p=0.004; p=0.03), or even 3 or more therapy lines (52/71, 73% *vs* 19/71, 26%, p<0.001). The following hazard ratios (HR) emerged from multivariate Cox regression analysis: HR 3.2 (95% CI 1.4-7), 2.9 (1.4-6.2), 3.4 (1.6-7.5), for Hb <6, 6-8, and 8-10 g/dL compared to patients with Hb >10, respectivelyAs regards complications, infections were observed in 14% of cases, mostly mixed AIHA (p=0.02); thrombosis occurred in 10% and acute renal failure in 3% of patients, with no relationship with AIHA type/Hb values. Evans' syndrome was more frequent in mixed or atypical cases (p=0.04) and in severe forms (74% with Hb<8 g/dL *vs* 26%, p=0.005), and was associated with higher relapse risk (HR 2.3, 95% CI 1.4-3.9). Seventy patients died during the follow-up, and 12 because of AIHA-related acute complications. Higher mortality was observed for infections (HR 5.8, 95% CI), acute renal failure (HR 7.6, 95% CI) and Evans' syndrome (HR 8.3, 95% CI).

Table 1.

	WAIHA (n=193)		CAD (n=109)	Mixed AIHA (n=56)	Atypical AIHA (n=20)
	IgG (n=159)	IgG+C (n=34)			
Hb (g/dL) median (range)	7.3 (2.1-14)	5.8 (2-10.7)	8.2 (4-13.5)	7 (2.9-11.5)	6.2 (3-9)
LDH ULN median (range)	1.7 (0-27)	1.8 (1-5)	1.4 (0-12)	1.9 (1-10)	2 (1-18)

Anemia					
Very severe anemia (Hb<6 g/dL)	44 (28%)	20 (58%)	10 (9%)	18 (32%)	10 (50%)
Severe anemia (6<Hb<8 g/dL)	63 (40%)	10 (30%)	41 (38%)	21 (38%)	7 (35%)
Moderate anemia (8<Hb<10 g/dL)	37 (23%)	2 (6%)	34 (31%)	14 (25%)	3 (15%)
Mild anemia (Hb>10 g/dL)	15 (9%)	2 (6%)	24 (22%)	3 (5%)	0 (0%)
Therapy					
No therapy	8 (5%)	0 (0%)	25 (23%)	2 (3%)	1 (5%)
1 line of therpy (n of pts, %)	151 (95%)	34 (100%)	84 (77%)	55 (98%)	19 (95%)
2 lines of therpy (n of pts, %)	59 (37%)	19 (56%)	51 (47%)	36 (64%)	7 (35%)
3 lines of therpy (n of pts, %)	23 (15%)	6 (18%)	26 (24%)	15 (27%)	4 (20%)
4 or more lines of therpy (n of pts, %)	7 (4%)	0 (0%)	11 (10%)	5 (9%)	2 (10%)
Complications					
Infections (n of pts, %)	23 (14%)	5 (15%)	10 (9%)	14 (25%)	0 (0%)
Thrombosis (n of pts, %)	23 (14%)	7 (20%)	15 (14%)	11 (20%)	2 (10%)
Acute renal failure (n of pts, %)	5 (3%)	2 (6%)	2 (2%)	2 (4%)	0 (0%)
Evans' (n of pts, %)	11 (7%)	4 (12%)	1 (1%)	5 (9%)	2 (10%)
Death (n of pts, %)	31 (19%)	7 20%)	22 (20%)	6 (11%)	3 (15%)
Death for AIHA (n of pts, %)	5 (3%)	2 (6%)	2 (2%)	3 (5%)	0 (0%)

Summary/Conclusions: In conclusion, we found that severity of anemia at onset was the major determinant of relapse risk. The lowest Hb levels were observed in patients with IgG+C WAIHA and atypical cases along with higher LDH levels and inadequate reticulocytosis, advising strict clinical observation in these patients.

P617

HEME BINDS ANNEXIN-A5 DURING HEMOLYSIS AND PREVENTS ITS INTERACTION WITH CELL MEMBRANE PHOSPHATIDYLSERINE DURING SICKLE CELL DISEASE

S. Sadoudi[1], S. Le Jeune[2], D. Charue[1], L. Kiger[3], L. Roumenina[4], C. Boulanger[1], O. Blanc-Brude[1,*]
[1]INSERM UMRs970 ParCC, INSERM, Paris, [2]Hôpital Avicenne, Médecine Interne, Assistance Publique-Hôpitaux de Paris, Bobigny, [3]Institut Mondor de Recherche Biomédicale, Hôpital Henri Mondor, INSERM, Créteil, [4]Centre de Recherche des Cordeliers, INSERM, Paris, France

Background: Intravascular hemolysis, such as in sickle cell disease (SCD), is characterized by red blood cell damage, high levels of cell-free heme and extracellular vesicles in plasma, along with inflammation and tissue injury. Stressed leukocytes, platelets, endothelial and red blood cells shed microparticles (MP) that bear externalized phosphatidylserine (PS) at their surface and promote tissue injury. Conversely, intracellular annexin-A5 acts as an inhibitor of externalized PS at the surface of cells and MP. Annexin-A5 is thought to orchestrate vesicle trafficking, promote cell membrane repair, protect against PS-mediated effects and enforce anti-inflammatory and anti-thrombotic control.
Aims: We investigated a possible functional relationship between intravascular hemolysis and annexins. We hypothesized that annexins, and annexin-A5 activity in particular, is blocked by extracellular heme as it is released in plasma during intravascular hemolysis.
Methods: In order to test the heme-annexin-A5 relationship, we measured PS-, PS+, CD235a+ and annexin-A5+ circulating MP in adult SCD patient and matched control plasmas. We explored annexin-A5 expression in plasma and blood cells by Western blots and ELISA, and also quantified the PS-binding functionality of plasma annexin-A5 using a self-designed immunocapture assay and purified PS+ MP. Moreover, we investigated molecular interactions between purified heme and recombinant human annexin-A5 by surface plasmon resonance (BiaCore and Proteon), absorbance shift assay and protein autofluorescence quenching. Finally, we put forward a model of heme-annexin-A5 docking by 3D molecular rendering.
Results: Immunocapture of plasma annexin-A5 revealed an association with heme (Abs398 nm signature) during SCD, especially during acute hemolytic events. In SCD plasma, we found increased total annexin-A5, but virtually undetectable levels of functional annexin-A5, contrary to controls. This implied a greatly reduced ratio of functional annexin-A5/circulating PS+ MP. Moreover, purified heme bound readily to annexin-A5 with relatively high affinity in vitro, as demonstrated using absorbance shift, autofluorescence quenching and plasmon surface resonance assays, with human serum albumin and hemopexin in competition tests. Annexin-A5 autofluorescence was partly quenched by heme addition, which also produced a significant red-shift in heme absorbance wavelengths, implying that a tight and direct molecular interaction was possible. Hemoglobin and heme also triggered annexin-A5 aggregation in vitro, producing high molecular weight and heat-resistant multimers, observed by western blot. Surface plasmon resonance studies revealed that annexin-A5 contains several sites for heme binding, some with very low affinity, while others are estimated with a Kd in the 10-6m range, rather similar to that of albumin. Part of the heme bound to annexin-A5 remained in place, even in the subsequent addition of the high-affinity heme-scavenger hemopexin. 3D molecular docking rendering suggested that heme may bind to the PS-binding groove of annexin-A5, thereby preventing further interactions with PS. Finally, heme completely prevented the binding of exogenous annexin-A5 to purified PS+ MP and plasma MP, as well as their subsequent detection by flow cytometry.
Summary/Conclusions: Together, our data suggest that PS-neutralizing annexin-A5 is inhibited by cell-free heme. This heme-mediated inhibition of annexin-A5 may display physiopathological relevance, contribute to the accumulation of PS+ MP in plasma during intravascular hemolysis, and more specifically of RBC MP during SCD which can participate to the degradation of the vascular function.

P618

USE OF PEGYLATED-CARBOXYHEMOGLOBIN BOVINE FOR THE TREATMENT OF SICKLE CELL DISEASE ASSOCIATED LEG ULCERS: RESULTS FROM A PHASE 2 SAFETY STUDY

J. Valentino[1], H. Misra[1,*], L. Lopez[2], G.M. Paulino[3]
[1]Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States, [2]Hematology, Centro Hemato-Oncológico Paitilla, Royal Center, Panama, [3]Hematology, Hospital General Plaza de la Salud, Santo Domingo, Dominican Republic

Background: Leg ulcers are a common complication of sickle cell disease (SCD). The pathophysiology of SCD leg ulcer is complex and may include obstruction of blood vessels by sickled red cell, chronic anemia, depleted nitric oxide bioavailability (resulting in impaired endothelial function), infection, thrombosis and excessive vasoconstriction. These events lead to progressive peripheral de-vascularization and tissue necrosis, such that even minor lower-leg wounds can become persistent ulcers, with no tendency to heal after months of appropriate treatment. PEGylated-Carboxyhemoglobin bovine (PEG-COHb; SANGUINATE) is an oxygen carrying agent with anti-inflammatory activity. A study of safety and effectiveness was undertaken in SCD patients with chronic leg ulcers to determine the safety of this investigational drug administered in as a once weekly infusion for either 4 or 6 weeks.
Aims: To assess the safety and efficacy of repeated doses of PEG-COHb on SCD leg ulcers.
Methods: The study was an escalating, repeated-dose, open-label, Phase 2 study to test PEG-COHb at 320mg/kg (8 mL) in subjects suffering from leg ulceration associated with SCD. It was conducted in Panama and the Dominican Republic. All enrolled subjects underwent a 3-week Run-In Period, during which they received standard of care treatment for wound management. During the Treatment Period, subjects were assigned sequentially to Cohort 1 or Cohort 2. Cohort 1 received 4 once-weekly doses by 2-hour intravenous infusion of SANGUINATE. Following the completion of Cohort 1, the safety findings were reviewed prior to initiating Cohort 2. Cohort 2 received 6 once-weekly infusions. In addition to the study drug, subjects continued to receive standard of care during the Treatment Period. One week after the end of Treatment, subjects returned to the study center for a Final Visit. The following assessments were done: safety: Safety was assessed by recorded adverse events (AEs), laboratory assessments (hematology, chemistry, and urinalysis), vital signs, concomitant medications, and 12-lead electrocardiograms (ECGs), efficacy: Wound pain, wound appearance and condition, wound size, wound vascular status (Venous Clinical Severity Score; VSCC), quality of Life: Quality of life was assessed using the Short Form-12 v2 Health Survey (SF-12).
Results: The administration of once-weekly infusions of PEG-COHb was well tolerated. Treatment emergent adverse events (mild pyrexia, moderate wors-

ening anemia) considered related to study drug were report in 2/10 patients. Increases in mean arterial pressure were anticipated due to the oncotic effects of this colloidal drug, but with no consistent pattern to the changes. Changes in ECG intervals were seen in a few subjects, but those changes were not considered clinically meaningful. There were no clinically meaningful changes in laboratory values, physical examinations, or concomitant medications. There were no statistically significant changes from Baseline in leg ulcer pain and wound surface area for either Cohort. All of the wound assessments remained relatively consistent throughout the study. There were slight decreases in total VCSS at most time points, indicating slight improvement in vascular status. Results were similar for the individual scores.

Summary/Conclusions: The administration of 4 or 6 once-weekly infusions of PEG-COHb at a dose of 320mg/kg was generally well tolerated. Slight improvements in total and individual VCSS are promising and may warrant further study with prolonged repeated doses of PEG-COHb.

P619

NON-RENAL DETERMINANTS OF ENDOGENOUS ERYTHROPOIETIN LEVELS IN SICKLE CELL DISEASE

K. Gardner[1,2,*], C. Sharpe[3,4], M. Awogbade[1]
[1]Haematological Medicine, King's College Hospital, [2]Molecular Haematology, King's College London, [3]Renal Medicine, King's College Hospital, [4]Renal Medicine, King's College London, London, United Kingdom

Background: Sickle cell disease (SCD) is characterized by chronic hemolysis and inflammation. Elevated levels of erythropoietin (EPO) drive expansion of erythropoiesis to compensate for increased red cell destruction. EPO is produced in response to anemia and tissue hypoxia. Previous studies in SCD suggest that EPO is inappropriately low for the degree of anemia but the reasons are unclear.

Aims: To perform a retrospective analysis of data collected as part of routine clinical care to examine the relationship between serum EPO and degree of anemia, HbF levels, oxygenation status, hemolytic rate, alpha globin status, inflammation, serum ferritin and renal function.

Methods: King's College Hospital (London, UK) has a large SCD population. All patients with HbSS or HbSβ^0 thalassemia who had a serum EPO level measured between 2007 and 2013 were included. Sickle genotype, alpha genotype, "baseline" HbF (no hydroxycarbamide, transfusion or pregnancy) and demographic data were recorded. Other clinical variables were obtained from the same day as EPO levels (medications, laboratory values and oxygen saturation). Serum EPO was measured by chemiluminescence immunoassay (Siemens Immulite XPi). Exclusion criteria were: active vaso-occlusive crisis, transfusion within 8 weeks, chelation, erythropoiesis stimulating agent therapy, home oxygen, pregnancy and renal disease (eGFR<60mls/min or urine albumin creatinine ratio>30). Data analysis was performed in IBM SPSS Statistics 22. Skewed variables were log transformed and estimated GFR was calculated using the MDRD formula. Normalized variables were correlated with Ln EPO using Pearson's correlation, ordinal variables using one way ANOVA, and binary variables using independent samples 2-tailed t-test. Multivariate linear regression using Ln EPO as the outcome was performed.

Results: 245 adult (≥17 years) SCD patients (all of African or African-Caribbean origin) met the inclusion criteria. Of the 245, 241 had HbSS and 4 HbSβ^0, 100 were male and 145 female, and mean age was 31.2 +/- 11.6 years. 221 had known alpha globin status: 21 α-/α-, 81 αα/α-, 118 αα/αα, 1 αα/ααα. Univariate analysis revealed a weak/moderate negative association between Ln EPO and Hb (*r*=-0.383, p<0.001). Significant associations were also seen between Ln EPO and: negative correlation with PCV, oxygen saturations, Ln HbF; and positive correlation with Ln CRP, LDH, STFR, Ln uACR, cystatin C. One way ANOVA showed alpha globin status to be associated with EPO (higher EPO with more alpha chains). There was no significant association between EPO and: age, sex, eGFR, white cell count, and use of hydroxycarbamide. Multivariate linear regression (N=175) revealed alpha globin status, Hb, CRP and HbF remained independently associated with Ln EPO level, see table.

Table 1. Multivariate analysis of EPO.

	Beta (95% CI)	p-value
Alpha globin category	-.188 (-.311 to -.066)	.003
Hb	-.016 (-0.022 to -0.011)	.000
LnCRP	.115 (0.008 to 0.222)	.035
LnHbF	-.117 (-.209 to -.024)	.014

where alpha= 0 if aa/aa; 1 if aa/a-; 2 a-/a-

Summary/Conclusions: In our SCD cohort without renal dysfunction EPO was elevated. Unlike the non-sickle setting where Ln EPO is very strongly (negatively) correlated with Hb levels, in our SCD cohort we have found only a mild/moderate correlation. Instead, additional associations were seen between EPO and alpha globin status, CRP and HbF. Our findings suggest that in addition to Hb, other SCD severity markers influence EPO production. This may provide explanation for relative EPO deficiency, and have implications for considering therapeutic EPO in SCD.

P620

THE PHARMACOKINETICS (PK) OF GBT440 ARE SIMILAR IN ADOLESCENTS AND ADULTS WITH SICKLE CELL DISEASE (SCD)

C. Washington[1,*], R. Savic[2], A. Inati[3], J. Estepp[4], G. Woods[5], E. Fong[1], A. Hutchaleelaha[1], M. Tonda[1], G. Balaratnam[1], J. Lehrer-Graiwer[1]
[1]Global Blood Therapeutics, South San Francisco, [2]University of California, San Francisco, United States, [3]Rafic Hariri University Hospital, Beirut, Lebanon, [4]St. Jude Children's Research Hospital, Memphis, [5]Children's Mercy Hospital, Kansas City, United States

Background: Sickle cell disease (SCD) is caused by polymerization of Hemoglobin S (HbS), resulting in hemolysis and vaso-occlusion. Currently, no therapy achieving pancellular, direct inhibition of HbS polymerization is available for adults or children with SCD. GBT440 is a novel small molecular inhibitor which increases hemoglobin oxygen affinity, thereby preventing HbS polymerization and red blood cell sickling. This study represents the first evaluation of GBT440 in a pediatric population.

Aims: This study was designed to evaluate the safety and PK of GBT440 following a single and multiple doses in adolescents. In addition a population PK (PPK) model, based on data derived following single doses of GBT440, was developed to support the identification of future GBT440 dosing regimens for pediatric populations with SCD.

Methods: This is an ongoing, open-label, Phase 2a study in adolescents (12 to 17 years) with SCD (HbSS or HbS β^0thalassemia). Participants were enrolled after obtaining written informed consent/assent. This study is being conducted in 2 parts: Part A, single-dose, and Part B, multiple-dose for 24 weeks. The primary objective of Part A is PK and the primary objectives of Part B are safety and efficacy. PK samples to measure whole blood and plasma GBT440 concentrations were collected up to 15 days following single dose administration. Separate PPK models were developed to describe the concentration *versus* time profiles of GBT440 in whole blood and plasma using non-linear mixed effects modeling (NONMEM, version 7.3). The allometrically scaled adolescent PPK model was also used to estimate the appropriate single dose for subsequent evaluation in pediatric participants (6 to 12 years).

Results: Part A has been completed; 7 adolescents (3 males/4 females) received a single dose of GBT440 600mg. The median age of participants was 16 years (range 14 to 16 years) and the mean weight was 52.8 kg (range 44.6 to 65.8kg). GBT440 was well tolerated; there were no drug-related ≥Grade 3 adverse events (AE) or serious adverse events and the most common AE was Grade 1 nausea. A 2-compartment model with first order absorption best described the PK of GBT440 and is the same model structure as previously used for adults with SCD. GBT440 PK parameters (Table 1) are comparable to those derived in adults, suggesting that GBT440 PK in adolescents and adults are similar. Model validation confirmed this result with good agreement between the observed adolescent PK data and simulated profiles based on the adult GBT440 PK model.

Table 1.

Table 1 **Parameter Estimates from Whole Blood and Plasma GBT440 Population PK Models, Adults versus Adolescents Participants with SCD**

PK Parameters	GBT440 in Whole Blood Adults (RSE %)	GBT440 in Whole Blood Adolescents (RSE %)
CL (L/h)	0.43 (5)	0.37 (13)
V (L)	21.4 (6)	15 (17)
Ka (1/h)	0.34 (13)	0.19 (30)
	GBT440 in Plasma Adults (RSE %)	**GBT440 in Plasma Adolescents (RSE %)**
CL (L/h)	7.63 (5)	5.4 (6)
V (L)	373 (5)	329 (7)
Ka (1/h)	2.83 (14)	1.37

CL = apparent clearance, Ka = absorption rate constant, RSE = relative standard error, V = apparent volume of distribution; L= liters; h= hours

Summary/Conclusions: This is the first study used to develop a GBT440 PPK model in adolescent participants with SCD. Data suggests that similar GBT440 doses can be used in adolescents and adults. Part B has been initiated to evaluate multiple doses of GBT440 in adolescents. This PPK model can potentially be used to estimate individual PK parameters (*e.g.*, AUC) to support future GBT440 dose selection for evaluation in the pediatric population.

Gene therapy, cellular immunotherapy and vaccination

DEVELOPMENT OF TAX-REDIRECTED T-CELL IMMUNOTHERAPY FOR ADULT T CELL LEUKEMIA

K. Kawamura[1,*], Y. Tanaka[1,2], Y. Ishihara[1], H. Nakasone[1], S. Kako[1], S. Kobayashi[2], T. Ohmori[3], K. Uchimaru[4], S. Okamoto[5], J. Mineno[5], H. Shiku[6], S. Nishimura[7], Y. Kanda[18]
[1]Division of Hematology, Saitama Medical Center, Jichi Medical University, Saitama, [2]Division of Molecular Therapy, Institute of Medical Science, The University of Tokyo, Tokyo, [3]Department of Biochemistry, Jichi Medical University, Tochigi, [4]Department of Computational Biology and Medical Sciences, Graduate School of Frontier Sciences, The University of Tokyo, Tokyo, [5]Center for Cell and Gene Therapy, Takara Bio Inc, Shiga, [6]Department for Immuno-Gene Therapy, Mie University Graduate School of Medicine, Mie, [7]Center for Molecular Medicine, [8]Division of Hematology, Department of Medicine, Jichi Medical University, Tochigi, Japan

Background: Adult T cell leukemia/lymphoma (ATL) is an aggressive peripheral T-cell neoplasm caused by HTLV-1 virus infection and its prognosis remains very poor. Tax, which is the most important regulatory protein of HTLV-1, is associated with aggressive proliferation of host cells and is also a major target antigen for $CD8^+$ cytotoxic T-cells (CTLs). We previously analyzed the Tax-specific T-cell receptor (TCR) repertoire, phenotypes and functions of Tax-specific CTLs at the single-cell levels in HLA-$A24^+$ ATL patients who underwent allogeneic stem cell transplantation (allo-SCT). We found that a particular amino acid sequence motif (PDR) in the CDR3 region of TCR-ß was conserved in different patients and also within the same patient before and after allo-SCT, and the PDR(+) Tax-specific CTL clone selectively expanded in ATL long-term survivors as less-differentiated effector memory CTLs. Actually, the PDR(+) CTL showed not only strong binding activity for the Tax-tetramer but also strong killing activity against patients' HTLV-1-infected T-cells without any reaction against normal cells.
Aims: Currently, we are planning a redirected T-cell immunotherapy using the PDR(+) TCR genes for ATL. Therefore, we prepared donor-derived PDR(+) TCR-transduced T-cells and evaluated their cytotoxic efficiency against HTLV-1-infected T-cells and ATL-cells both *in vitro* and *in vivo* mouse model.
Methods: HLA-A24:02 restricted and Tax301-309-specific TCR-α/β genes were cloned from an established PDR(+) CTL clone and integrated into a retroviral siTCR vector (Tax-siTCR vector) encoding small-interfering RNAs (siRNAs) to knockdown endogenous TCR genes for the efficient expression of therapeutic TCRs. Then, $CD8^+$ T-cells of healthy volunteers were transfected with Tax-siTCR vector (Tax-siCTLs). First, cytotoxicity and cytokine production capability of the Tax-siCTLs against HTLV-1 infected T-cells or ATL-cells were evaluated using calcein-AM-based assay and flow-cytometric analysis, respectively. Next, to evaluate the *in vivo* anti-ATL effects by the Tax-siCTLs, the bioluminescence assay (*in vivo* imaging system) was performed. We generated a luciferase-gene transduced HLA-$A24^+$HTLV-1 infected cell-line, MT-2 (Luc-MT-2), and injected 1×10^6Luc-MT-2 cells into six-week-old NOD/Shi-scid,IL-2RγKO Jic (NOG) mice intraperitoneally. After the 3 weeks, 2×10^6Tax-siCTLs were administered via the tail vain weekly, for a total of 3 times. For comparison, non-integrated T-cells (Mock) were administered in the same way. These mice were monitored for tumor growth using IVIS system weekly.
Results: Tax-siCTLs showed specific and strong killing activity against both HTLV-1 infected T-cells and patients' ATL-cells without any reaction against control normal-cells. In addition, Tax-siCTLs produced a sufficient amount of cytokines such as IFN-γ, TNF-α, and IL-2 against HTLV-1 infected T-cells. In mice experiments, the bioluminescence of Luc-MT-2 in the mice treated with Tax-siCTLs had started to reduce gradually after 7 weeks, and finally became undetectable after 9 weeks. In addition, macroscopic anatomical findings in the treated mice were normal after 12 weeks. In contrast, the amount of bioluminescence in the mice treated with Mock or in the control mice without treatment had rapidly increased and all mice died by 9 weeks.
Summary/Conclusions: We confirmed that Tax-siCTLs could exert a strong anti-ATL effect without significant reaction against normal cells both *in vitro* and *in vivo*. The therapy using this PDR+ Tax-siCTLs has a potential to be a novel immunotherapy for ATL patients.

NHEJ-BASED GENE EDITING: A NOVEL GENE THERAPY APPROACH IN FANCONI ANEMIA HEMATOPOIETIC STEM AND PROGENITOR CELLS

F.J. Roman-Rodriguez[1,2,*], B. Diez[1,2], L. Alvarez[1,2], C. Risueño[1,2], R. Torres-Ruiz[3], M. Corton[2], C. Diaz de Heredia[4], J. Sevilla[5], C. Ayuso[2], J. Bueren[1,2], P. Rio[1,2]
[1]Division of Hematopoietic Innovative Therapies, CIEMAT/CIBERER, [2]Advanced Therapies Unit, IIS-Fundacion Jimenez Diaz (IIS-FJD, UAM), [3]Molecular Cytogenetics Group, Human Cancer Genetics Program, Centro Nacional de Investigaciones Oncologicas, Madrid, [4]Department of Haematology and Oncology, Hospital Universitario Vall d'Hebron, Barcelona, [5]Onco-Hematologia Pediatrica, Hospital del Niño Jesus, Madrid, Spain

Background: Allogenic transplantation of hematopoietic stem and progenitor cells (HSPCs) is the only current curative treatment for the bone marrow failure of patients with Fanconi Anemia (FA). However, the risks of GVHD and increased incidence of subsequent cancer, and the limited availability of matched donors hamper the application of this therapy in FA patients. For this reason correction of patients' HSPCs by gene therapy is considered a promising therapeutic alternative for these patients. In this context, gene editing constitutes a new step in the development of safe gene therapy approaches. Since non-homologous end joining (NHEJ) is the preferred DNA repair mechanism in HSPCs, and given that this mechanism has been reported to be enhanced in FA cells, we have tested the efficiency of a NHEJ-mediated gene editing approach to generate compensatory mutations that can restore the FANCA protein function in HSPCs from FA patients, mimicking reversions observed in mosaic patients.
Aims: To demonstrate the feasibility of using a NHEJ-based gene editing strategy to correct FA-A HSPCs as a result of the insertions and deletions (INDELs) generated in edited *FANCA* sequences in these cells.
Methods: Two different *FANCA* mutations from FA-A patient-derived lymphoblastic cell lines (LCLs) and primary HSPCs were targeted by the CRISPR/Cas9 system. INDELs generated as a consequence of the NHEJ repair were analyzed at different time points.
Results: Initial studies conducted in a FA-A LCLs carrying the biallelic c.295C>T point mutation that generates a premature stop codon (p.Q99X) showed targeting efficiencies around 20%. Next Generation Sequencing (NGS) not only revealed the generation of frame-restoring repair events, but also that these corrective NHEJ events conferred a marked *in vitro* proliferative advantage to the edited cells. Moreover reversion of the characteristic MMC hypersensitivity and restoration of the FANCD2 foci formation were observed in these cells. In addition, western-blot analysis confirmed the stable expression of FANCA protein. To further demonstrate the feasibility of the approach, a second *FANCA* associated mutation was targeted (c.3558insG, producing a frameshift and a premature stop codon -p.R1187EfsX28-) with even higher gene targeting efficiencies. Finally similar studies were conducted in three HSPCs samples from FA-A patients harboring the c.295C>T mutation, that showed targeting efficacies up to 36%. Moreover, NGS detected the presence of corrective NHEJ-repair events immediately after editing and evidenced up to 50-fold expansion of corrected cells after nine days in culture, confirming the functionality and proliferative advantage conferred by the frame restored alleles.
Summary/Conclusions: Our results demonstrate for the first time that NHEJ gene correction is feasible in FA HSPCs. The high efficacy of the NHEJ repair pathway in HSPCs together with the simplicity of the strategy, make this approach clinically relevant for the future treatment of the hematopoietic defects in FA patients.

P624

NOVEL, ENHANCED AND DUAL TARGETING CAR INVARIANT NKT CELL-BASED IMMUNOTHERAPY FOR CD1D+ B CELL MALIGNANCIES

A. Rotolo[1,*], O. Dubois[1], K. Goudevenou[1], K. Petevi[1], G.W. Cheung[2], M. Pule[2], J. Maher[3], A. Karadimitris[1]
[1]Medicine, Imperial College London, London, UK, [2]University College London, [3]King's College London, London, United Kingdom

Background: Anti-CD19 chimeric antigen receptor T cell (CART19) immunotherapy has shown promising clinical potential in relapsed/refractory mature B cell malignancies. However, only about half of patients benefit, highlighting the need for more effective CAR-based strategies. iNKT cells are rare but powerful immunoregulatory and cytotoxic T lymphocytes, playing a pivotal anti-tumor role. iNKT cells are restricted by CD1d, a non-polymorphic, phospho-/glycol-lipid-presenting HLA I-like molecule. We previously showed that CD1d, as well as on normal B cells, is also expressed on malignant CD19+ B cells in mantle cell lymphoma (MCL), marginal zone lymphoma (MZL) and chronic lymphocytic leukaemia (CLL).
Aims: We tested the hypothesis that bi-specific CAR*iNKT*19 cells, targeting simultaneously CD19 and CD1d via the CD19-specific CAR and their natural invariant TCR respectively, would be more effective than CART19 cells against CD19+CD1d+ B cell malignancies.
Methods: We optimized a novel protocol for manufacturing 2^{nd} (CAR2) and 3^{rd} (CAR3) iNKT cells expressing CAR19. Their *in vitro* reactivity was assessed in cytotoxicity (flow cytometry-based) and cytokine and cytotoxic granule release assays (intracellular staining and Luminex technology). *in vivo* reactivity was assessed in NSG xenograft assays, with monitoring of C1RCD1d tumour cell growth by bioluminescence imaging.
Results: Our optimised protocol for selection, lentiviral transduction and clinical scale expansion of CARiNKT cells within 3 weeks is suitable for frozen and fresh lymphocytes, derived from either healthy donors or cancer, including lym-

phoma patients. The manufacturing process consistently allows high CAR transduction efficiency of iNKT and T cells (75.31%±4.294 and 76.95%±14.76 respectively, n=8) and ensures the preservation of CD4− iNKT cells, which have been associated with a higher cytotoxic potential and anti-tumour activity. *In vitro* validation, using singly- or dual-positive CD1d and CD19 targets, demonstrated that CARiNKT19 cells are CD19-specific, retain their natural CD1d-restricted reactivity, and exert additive dual-specific cytotoxicity against CD1d+CD19+ targets. Additional functional dissection showed that activated CARiNKT19 cells, both fresh and cryopreserved, have the ability to produce cytotoxic granules and IFNγ faster and in larger amounts than same donor activated CART19 cells. Likewise, CAR2- and CAR3-iNKT cells are equally or more effective than their CART counterparts in killing CD19+CD1d+ lymphoid cell lines (B-lymphoblastoid C1RCD1d and lymphoma-derived Farage cells) and consistently more effective against primary MCL, MZL and CLL cells. Finally, in an *in vivo* NSG xenograft model of lymphoma, while survival of T- and NKT cell-treated animals was the same as that of untreated animals (P=0.23), both CART19 and CARiNKT19 cell-treated animals had significantly and comparably improved overall survival (P<0.001). However, compared to CART19, CARiNKT19 immunotherapy led to a better disease control, with earlier, more profound and sustained responses resulting in a significantly improved tumour free-survival (P=0.03).

Summary/Conclusions: In our pre-clinical *in vitro* and *in vivo* lymphoma models, CARiNKT19 are more effective than CART19 cells against CD19+CD1d+ B cell malignancies. Further, dual targeting by CARiNKT19 cells may mitigate against CD19-focused tumour escape after CAR immunotherapy, while the previously demonstrated role of donor iNKT cells in protection from aGVHD supports the development of CARNKT19 cells for 'off-the-shelf' use.

P625

A NOVEL CHIMERIC ANTIGEN RECEPTOR ENDOWS T CELLS WITH NK CELL-LIKE SPECIFICITY AND ATTACKS A WIDE RANGE OF HEMATOLOGICAL MALIGNANCIES AND CANCERS

Y. Kasahara[1,*], C. Shin[1], M. Imamura[1], N. Kubo[1], T. Takachi[1], H. Iwabuchi[1], S. Yoshida[1], A. Saitoh[1], C. Imai[1]
[1]Department of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

Background: Engineered T-cells expressing CD19-specific chimeric antigen receptors (CARs) have shown high response rates against relapsed and refractory B cell acute lymphoid leukemia (ALL). However, similar success has not yet been demonstrated in solid tumors, and the reasons for this are currently being investigated. One major obstacle is the difficulty in determining appropriate surface antigens that are effectively targeted by CAR-transduced immune cells. NKp44 is an activating receptor on human NK cells that is only expressed when the NK cells are activated, and which confers a marked increase in cytotoxicity against various tumors. Ligands for NKp44 have been reported to be expressed in various types of cancers, but not in healthy cells. Effective use of the ligand-binding domain of this receptor as an antigen recognition site of a CAR would thus allow a wide range of cancer cells to be attacked.

Aims: To determine the optimal CAR construct including the NKp44 immunoglobulin domain as a ligand-binding domain (NKp44-based CAR), with a view to developing effective CAR-T therapy against hematological malignancies and solid cancers.

Methods: We created several NKp44-based CAR constructs. Human T cells from healthy donors were stimulated with anti-CD3/CD28 beads and recombinant interleukin-2. Human NK cells were stimulated using K562-mb15-41BBL feeder cells, as previously reported (Imai C, 2005). Activated T cells or NK cells were then subjected to retroviral transduction with the CAR gene and the phenotypic and functional characteristics of CAR-T cells engrafted with the various NKp44-based CARs were compared. We determined if NKp44-ligands were present on the cell surface of various types of malignant cell lines using recombinant human NKp44 Fc chimeric protein.

Results: Surface expression of ligands for NKp44 was confirmed in a wide range of tumor cell lines including acute myeloid leukemia (AML; KG-1, THP-1, U937, K562, Kasumi-1, Kasumi-6), T-cell ALL (MOLT-4, HSB2, Peer, Jurkat), B-cell ALL (OP-1), Burkitt's lymphoma (Raji), osteosarcoma (NOS-10, NOS-1, NOS-2, SaOS-2, U2OS,mg-63), rhabdomyosarcoma (RMS-YM, Rh28), and neuroblastoma (NB1, NB16, IMR-32, SK-N-SH). Different expression levels of CAR were observed among the NKp44-based CARs created in this study, in which the major CAR domains, except for the ligand-binding domain, were derived from various components including NKp44, CD8α, CD28, or CD3ζ. A combination of the hinge domain from NKp44, transmembrane domain from CD28, and intracellular signaling domain from CD3ζ yielded the highest surface expression of CAR on both T cells and NK cells. T cells transduced with this CAR showed enhanced cytotoxicity against various target cells including AML, T-cell ALL, and B-cell ALL, but did not attack normal T cells. CAR-T cells also showed increased production of interferon-gamma and granzyme B. The hinge domain of NKp44 has been suggested to play a role in ligand binding (Koch J, 2013), but the details are poorly understood. Intriguingly, replacement of the hinge domain from NKp44 significantly reduced cytotoxic function, though CAR expression levels remained similar.

Summary/Conclusions: T cells transduced with NKp44-based CARs show enhanced activities against various tumor cells. The extracellular hinge region of NKp44 appears to play an important role in ligand binding and/or recognition. NKp44-based CARs may represent a promising candidate for novel immune therapies targeting a wide range of cancers.

P626

NKP30-CAR REDIRECTED HUMAN T LYMPHOCYTES INDUCE POTENT ANTITUMOR IMMUNITY TO LEUKEMIA CELL LINES AND PATIENT-DERIVED ACUTE MYELOID LEUKEMIA IN NSG XENOGRAFT MODELS

P. Ploch[1], S.A. Khan[1], M. Theobald[1], U. Hartwig[1,*]
[1]III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR)-redirected T cells has evolved as a highly effective individualized immunotherapy for leukemia and solid cancer. In particular, clinical trials using CD19 CAR expressing T lymphocytes to combat CD19$^+$ lymphomas have revealed compelling results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as *e.g.* CD33 and CD123 CAR expressing T cells induce potent immune responses not only to AML blasts but also recognize normal hematopoietic stem cells (HSC). In contrast, B7H6, a member of the B7 family, is frequently expressed on various tumor cells including AML blasts while not detectable on normal tissues, and is recognized by the natural killer (NK) cell activating receptor NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-associated transcript 3, a nuclear factor that is secreted and translocated to the cell surface in stressed and transformed cells.

Aims: In the current study, we thus explored the use of human T cells redirected to express a NKp30-CAR for inducing effective antileukemic immunity *in vitro* and in vivo to the erythrogenic leukemia line K562 and primary AML blasts in NSG xenograft mouse models following ACT.

Methods: PBMCs or MACS® purified human T cells were polyclonally stimulated and reprogrammed with a CAR composed of the extracellular region of the NKp30 receptor fused to the CD3ζ chain signaling domain (kindly provided by Dr. S. Klobuch, Dept. of Internal Medicine 3, Medical University Regensburg, Germany) by retroviral gene transfer. Transduced T cells were further selectively expanded utilizing puromycin resistance present on the retroviral backbone, and NKp30 expression was determined by flow cytometry. IFN-γ ELISPOT analyses and cytotoxicity assays were performed to assess antileukemic responses to leukemia lines and primary AML blasts *in vitro* and *in vivo* using NSG xenografts and adoptive transfer of redirected T cells. Expression of B7H6 in target cells was confirmed by RNA-based RT PCR.

Results: Following transduction and puromycin selection ≥90% of CD3$^+$ T cells expressed the NKp30 CAR. In addition, most T cells displayed an effector-memory phenotype. Upon coculture with the B7H6 expressing targets such as K562 and HL-60 (myelogenous leukemia cell lines), NALM 16 (pre-B-ALL) and patient-derived AML samples (*e.g.* MZ506 and MZ987) NKp30-redirected T cells elicited potent IFN –γ release and exhibited cytolytic activity to both leukemia lines and primary AML blasts in vitro. These responses were specific as *e.g.* no reactivity to the B7H6 negative myeloma line U266 was observed. We then evaluated antitumoral responses of NKp30-redirected T cells in vivo. Upon adoptive transfer of NKp30-CAR T cells into NSG mice engrafted with K562 significant reduction of tumor burden was observed. Moreover, injection of 1 - 5x10^6 HLA-matched, NKp30-CAR redirected CD3$^+$ T cells into NSG mice showing up to 5% engraftment of patient derived AML blasts and thus resembling a clinically relevant minimal residual disease status at time of ACT resulted in clear leukemia regression. Further experiments *e.g.* to elaborate to what extent CD4$^+$ and CD8$^+$ T cells contribute to this antileukemic immunity are in progress.

Summary/Conclusions: These studies demonstrate that human T lymphocytes can be successfully redirected to acute leukemia by NK cell activating receptor based CARs such as the NKp30-CAR. As its ligand B7H6 has not been reported to be expressed on CD34$^+$ HSC, this antigen might be an interesting target for adoptive immunotherapy to AML.

P627

PRECLINICAL TESTING OF ADOPTIVE T-CELL RECEPTOR GENE TRANSFER IN COMBINATION WITH CHECKPOINT INHIBITORS AS A NOVEL THERAPY FOR MULTIPLE MYELOMA

H. Echchannaoui[1,2,*], E. Amann[1,2], E. Antunes[1], M. Theobald[1,2,3]
[1]Third Department of Medicine (Hematology, Oncology and Pneumology), University Medical Center Mainz, Mainz, [2]German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, German Cancer Research Center (DKFZ), Heidelberg, [3]Research Center for Immunotherapy (FZI), University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) based on T-cell receptors (TCR) or chimeric antigen receptor (CAR)-engineered T cells has achieved tremendous success in the treatment of cancer, especially B-cell malignancies. The

impressive therapeutic results recently obtained with checkpoint inhibitors have opened a new era in the field of cancer immunotherapy. Yet, clinical responses are still often observed either transiently or in a minority of patients. This underscores the need for an improved understanding of underlying factors limiting the efficacy of T cell-based immunotherapy and its wide application.
Aims: We explored an immunotherapeutic combination strategy to unleash the full anti-tumor response of adoptively transferred antigen-specific T cells. We propose to target multiple myeloma (MM) tumor cells in our established xenograft *in vivo* adoptive cell therapy model by T cells equipped with two optimized TCRs specific for HLA-A2.1-restricted MDM2 and p53 epitopes in combination with checkpoint inhibitors.
Methods: Human T cells from healthy donors were retrovirally transduced with MDM2- and p53-specific TCRs and expression levels were analyzed by flow cytometry. MDM2 and p53 protein expression in MM cell lines was determined by Western blot. The therapeutic efficacy of adoptive TCR transfer was evaluated in NOD-scid IL2R gamma chain^{null}(NSG) mice engrafted (s.c) with HLA-A2.1-expressing NCI-H929 MM cell line. In the combination checkpoint inhibitor approach, mice were treated (i.p) with anti-PD-1 (Nivolumab). Tumor growth was monitored and intratumoral alterations (in particular expression of relevant tumor and T cell antigens) in ex-vivo tumors were analyzed by flow cytometry. Tumor-infiltrating lymphocytes (TILs) were also characterized by flow cytometry.
Results: Adoptive transfer of dual MDM2/p53-specific TCR equipped T cells showed a superior anti-tumor response *in vivo* compared to single TCR treatment, demonstrating the need to target multiple MM antigens to circumvent tumor escape mechanisms associated with down-regulation of antigen. Yet, we observed a strong up-regulation of PD-L1 expression in tumor cells *in vivo* and enhanced PD-1 expression in TILs which may limit the efficacy of antigen-specific TILs. Accordingly, *in vivo* ACT experiments combined with anti-PD-1 inhibitor, demonstrated the synergistic therapeutic potential of this approach as compared to single agent. Yet, it does not result in complete tumor eradication suggesting that targeting one single immune checkpoint receptor is not sufficient to drive a full anti-tumor response.
Summary/Conclusions: Combination checkpoint inhibitor approach has demonstrated synergistic potential in our ACT experimental MM model and forms the basis for a novel multi-modal immunotherapeutic combination treatment for multiple myeloma.

P628

ENGINEERED T CELLS TOWARDS BAFF RECEPTOR: A NOVEL STRATEGY TO EFFICIENTLY TARGET B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

N. Turazzi[1,*], G. Fazio[1], V. Rossi[1], A. Rolink[2], G. Cazzaniga[1], A. Biondi[3], C.F. Magnani[1], E. Biagi[1]
[1]M. Tettamanti Reserach Center, Department of pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy, [2]Department of Biomedicine, University of Basel, Basel, Switzerland, [3]M. Tettamanti Reserach Center, Department od pediatrics, University of Milano Bicocca S.Gerardo Hospital/Fondazione MBBM, Monza, Italy

Background: B-cell Acute Lymphoblastic Leukemia (B-ALL) is most common in children (80%), but it has also a peak of incidence in adult age. Immunotherapeutic approaches targeting the CD19 molecule paved the way for the treatment of relapsed and refractory lymphoblastic leukemia, which remains a major therapeutic challenge. Recently, the emergence of relapses with CD19-epitope loss in 10-30% of treated patients has been reported[1]. This newly identified escape mechanism has been recently shown to be related to the combination of deleterious mutations and emergence of alternatively spliced RNA isoforms, as effect of selective pressure[2]. B-cell Activating Factor (BAFF) Receptor is a transmembrane protein which is fundamental for B-cell maturation and survival. Moreover, the expression of this receptor is restricted to mature B cells and, interestingly, is not present on bone marrow B-cell precursors[3]. Recent studies reported the over-expression of BAFF Receptor (BAFF-R) in various B-cell malignancies such as B-ALL, B lymphoma, chronic lymphocytic leukemia and myeloma[4,5]. In the context of B-ALL leukemic cells express both BAFF and BAFF-R suggesting the presence of an autocrine signalling loop[6]. BAFF is also expressed in bone marrow microenvironment by endothelial cells which support the proliferation and the survival of primary B-ALL blasts[4].
Aims: In the current study, we aimed to develop a chimeric antigen receptor (CAR)- mediated immunotherapeutic approach targeting the BAFF-R molecule.
Methods: We characterized the expression of BAFF-R in B-ALL primary samples. As immunotherapeutic approach to target BAFF-R molecule, we developed six anti-BAFFR.CARs that differ for the inversion of the VH and VL and the length of the spacer domain (herein long, intermediate and short according to the presence of entire CH2CH3 domain, of CH3 only or complete absence). Cytokine-induced Killer (CIK) cells, an heterogeneous populations of CD3+ effector lymphocytes with acquired NK-like cytotoxicity enriched in highly efficient cytotoxic CD3+CD56+ cells, were engineered using an improved *Sleeping Beauty* (SB) transposon platform and used as effector population.
Results: Here we showed that BAFF-R is highly expressed in B-ALL primary samples at the onset and relapse. In order to develop a chimeric antigen receptor (CAR) approach targeting BAFF-R molecule, six anti-BAFFR CAR genes that differ for the inversion of the VH and VL and the length of the spacer domain have been generated. Cytokine-induced Killer (CIK) cells, engineered using an improved *Sleeping Beauty* (SB) transposon system, stably expressed anti-BAFFR.CARs, and maintained their characteristic phenotype. Among the newly constructed CARs, the shortest VHVL anti-BAFFR.CAR exerted the highest anti-leukemic activity towards target cells, such as NALM-6, with an *in vitro* killing activity of 60%. We also evaluated later effector functions in terms of cytokine release by intracellular staining (8,9±2% of IFN-γ and 16,4±5,5% of IL-2 producing cells). Importantly, we also detected a specific cytotoxic activity towards primary B-ALL blasts (average 65,6±4,5%, n=9). Combining the INVsh.CAR with CD19.CAR we detected a superior antitumor activity towards ALL targets (78,1±6,9% and 72,2±2,9% of tumor lysis respectively *vs* NALM6 and primary B-ALL blasts) compared to single population *per se*. Furthermore, by using a sample collected from a patient relapsed with CD19 negative disease, we demonstrated the ability of the INVsh.CAR to lysate CD19-negative blasts.
Summary/Conclusions: Taken together, these findings make this receptor a safe and attractive target for a second line B-ALL immunotherapy in case of relapse after CD19-targeting therapies or for a double targeted approach. Being restricted to mature B cells, but absent on precursors and plasmablasts, our strategy could have an inferior toxicity concerning the emergence of B-cell aplasia observed in patients treated with anti-CD19 CAR-modified T cells.

P629

EXPLORING HUMAN TCR- AND CAR-REDIRECTED INKT CELLS FOR ADOPTIVE CELLULAR THERAPY

B. Mir[1], S. Khan[1], M. Theobald[1], U. Hartwig[1,*]
[1]III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: T cell receptor (TCR) - or chimeric antigen receptor (CAR) redirected T cells have substantially improved adoptive cellular therapy (ACT) for acute leukemias and show great promise for solid cancer. However, functional heterogeneity and advanced differentiation of *ex vivo* expanded redirected lymphocytes limits their therapeutic potential and consistent efficacy. Invariant (type I) natural killer T (iNKT) cells have been demonstrated not only to promote effector functions of dendritic cells (DC), natural killer (NK) cells and T cells but also to localize to tumors and have inherent antitumor properties. Moreover, as these cells are further restricted to the monomorphic, HLA class I-like CD1 molecule expressed only on a few cell types with limited alloreactive potential, all these features make iNKT cells as attractive alternative carriers for redirected immunotherapy.
Aims: In the current proof of concept study we therefore explored human, AML-reactive TCR- and CD19 CAR-redirected iNKT cells for their potential to induce antitumoral responses to leukemia cell lines as well as patient derived, primary AML blasts.
Methods: iNKT cells expressing the invariant TCR composed of the Vα24Jα18/Vβ11 chains were immuno-magnetically isolated from PBMC derived from adult healthy donors using Vβ11-Ab (6B11)-conjugated, anti-iNKT microbeads (Miltenyi Biotec) and expanded *in vitro* upon coculture with autologous, α-galactosyceramide (α-GalCer) loaded DC in the presence of low amounts of interleukin (IL)-2. iNKT cells were retrovirally transduced on day 6 after stimulation and selected for TCR or CAR expression utilizing a virally transduced puromycin resistance. While phenotypic analyses on iNKT markers and on the percentage of redirected cells were performed by flow cytometry functional assays such as IFN-γ ELISPOT and cytotoxicity assays were carried out using CD19$^+$ NALM-16 (pre B-ALL) and primary AML (MZ653) cells as targets.
Results: Following isolation of 0.7 - 0.8 x 10^6Vα24/Vβ11$^+$ iNKT cells from PBMC we achieved on average a 120-fold expansion 21-28 days after stimulation with GalCer loaded, irradiated autologous DC and 25 U IL-2. Additional use of lenalidomide to promote expansion as described previously had no effect. Expanded iNKT cells were mainly CD4$^+$(83%) and about 80% of cells expressed the natural killer receptor CD161 described as iNKT maturation marker but showed limited or virtually no expression of typical NK markers such as CD56 and CD16. Following retroviral transduction and selection for 6 days >80% of TCR (5B2)- and CD19 CAR-redirected iNKT cells were obtained. Subsequent functional analyses revealed that both iNKT cells expressing the AML-reactive TCR 5B2 as well as CD19-CAR iNKT cells demonstrated substantial release of IFN-γ and elicited potent antileukemic responses to AML MZ653 and NALM-16 in vitro. Studies to examine their cytotoxic potential potential *in vivo* using NSG xenograft models are currently in progress.
Summary/Conclusions: These studies demonstrate that purified human Vα24/Vββ11$^+$ iNKT cells expanded from PBMC can be successfully redirected to acute leukemia both by TCR and CAR expression. Engineered iNKT cells might therefore be promising alternative carriers for redirected ACT or beeing used in combination with redirected T cells as combined immunotherapy.

P630

SPECIFIC TARGETING OF ACUTE MYELOID LEUKEMIA BY THE USE OF ENGINEERED CIK (CYTOKINE-INDUCED KILLER) CELLS EXPRESSING THE ANTI-CD33 CHIMERIC ANTIGEN RECEPTOR (CAR)

M.C. Rotiroti[1,*], S. Arcangeli[1], C.F. Magnani[1], C. Cappuzzello[1], A. Biondi[1], S. Tettamanti[1], E. Biagi[1]

[1]Department of Pediatrics, University of Milano-Bicocca, San Gerardo Hospital/Fondazione MBBM, Tettamanti Research Center, Monza, Italy

Background: Acute Myeloid Leukemia (AML) is an aggressive malignancy still associated with high relapse rates when treated with conventional chemotherapeutic and hematopoietic transplantation regimens. In search for alternative strategies, great interest has been posed on antigen-specific immunotherapies and in particular on T cells redirected with Chimeric Antigen Receptors (CARs) that have shown exciting results in cancer therapy, especially in the context of B-cell malignancies. CD33 is the only validated target in AML so far and represents a suitable antigen to be targeted with CAR-T cells, being broadly expressed on AML blasts.
Aims: The aim of the present study is to preclinically evaluate the efficacy and safety profiles of CD33 CAR redirected Cytokine Induced Killer (CIK) cells alone and in combination with standard chemotherapeutic agents.
Methods: Here we proved the feasibility of harnessing Cytokine Induced Killer (CIK) effector cells with a third generation anti-CD33.CAR through the non viral Sleeping-Beauty transposon system, starting from fresh and frozen healthy mononuclear cells (PBMCs) and also from frozen primary AML samples. The *in vitro* anti-AML activity of CD33.CAR-CIK cells is assessed by means of cytotoxicity, proliferation and cytokine production assays upon challenge with AML cell lines and primary samples. The *in vivo* efficacy of CD33.CAR CIK cells is evaluated in NSG mice transplanted with AML cell lines (MA9-NRas cells) and primary samples. Moreover, to investigate the potential benefit of CD33.CAR CIK cell immunotherapy in combination with standard-of-care treatments, xenograft chemotherapy models is exploited, by using standard AML induction therapy drugs (Ara-C and doxorubicin).
Results: CD33.CAR-CIK cells were able to induce a potent anti-leukemic activity as compared to unmanipulated CIK cells, in terms of specific killing (up to 70%), proliferation (up to 40% of $Ki67^+$CAR-CIK cells) and cytokine production (up to 30% for both IL-2 and IFN-gamma producing CAR-CIK cells) when challenged with both AML cell lines and primary leukemic cells. By treating MA9-NRas cell grafted mice with the already established "5+3" induction chemotherapy protocol, we confirmed that chemotherapy is able to significantly reduce the leukemic burden from around 20% to 0.1% in the bone marrow. Since the AML disease is not totally eradicated, this model will be therefore suitable to further investigate the efficacy of the CD33.CAR-CIK cells immunotherapy on the chemotherapy resistant/residual AML cells.
Summary/Conclusions: Having demonstrated the significant *in vitro* anti-leukemic activity of SB-modified CD33.CAR-CIK cells we next aim to assess their efficacy *in vivo*, particularly against the resistant/residual AML cells that were not eradicated by standard chemotherapy treatment. Moreover, envisaging a safer clinical translation of this immunotherapeutic approach, a transient CAR expression, by using CD33.CAR coding mRNA, is under investigation, in order to limit the potential myelotoxicity due to the long-term off-target effect on normal hematopoietic stem/myeloid progenitor cells. Finally, if successful, our results will provide the preclinical validation of CD33.CAR-CIK cell immunotherapy, supporting its development to the clinic.

P631

UPDATE ON THE FIRST PATIENTS WITH SEVERE HEMOGLOBINOPATHIES TREATED WITH LENTIGLOBIN GENE THERAPY

J.-A. Ribeil[1], S. Hacein-Bey-Abina[1], E. Payen[2], E. Magrin[1], A. Magnani[1], M. Semeraro[3], L. Caccavelli[1], F. Touzot[1], F. Lefrere[1], F. Suarez[1], O. Hermine[1], V. Brousse[1], C. Sandler[8], M. de Montalembert[1], S. Blanche[1], P. Leboulch[2], M. Cavazzana[1,*]
[1]Necker Hospital, Paris, [2]Institute of Emerging Diseases and Innovative Therapies (iMETI), CEA & University of Paris-Sud, Fontenay-aux-Roses, [3]Université Paris Descartes, [4]Hôpital Saint Louis, [5]Université Paris Diderot, [6]Hôpital Henri Mondor, [7]Hôpital Cochin Saint Vincent de Paul, Paris, France, [8]bluebird bio, Cambridge, United States

Background: Insertion of an anti-sickling β-globin gene variant into hematopoietic stem cells (HSCs) could reduce or eliminate symptoms of severe sickle cell disease (SCD) and transfusion requirements in transfusion-dependent β-thalassemia (TDT). LentiGlobin Drug Product (DP) contains autologous CD34+ cells transduced with the BB305 lentiviral vector, which encodes a human β-globin gene containing a single point mutation (A^{T87Q}) designed to confer anti-sickling properties similar to γ-globin. We recently (ASH 2016) reported 23 months of follow-up for a patient with SCD, and 12−34 months of follow-up for 4 patients with TDT.
Aims: To evaluate the safety and efficacy of LentiGlobin gene therapy for severe hemoglobinopathies.
Methods: Patients 5-35 years old with severe SCD (*e.g.*, ≥2 acute chest syndrome episodes or ≥2 vaso-occlusive crises [VOC] in the preceding year) or TDT (≥100 mL/kg of packed red blood cells [RBCs] per year) were enrolled. After informed consent, autologous CD34+ cells were collected and transduced with the BB305 vector. Patients underwent myeloablative conditioning with busulfan prior to infusion of transduced cells. Patients were then monitored for hematologic engraftment, vector copy number (VCN), genetically engineered hemoglobin (HbA^{T87Q}) levels, and adverse events (AEs). Disease-specific assessments included transfusion requirements for TDT, or VOCs and hospitalizations for SCD.
Results: As of 9 September 2016, 1 patient with severe SCD (male; 13 years old) and 4 patients with TDT (2 male, 2 female; 16−19 years old) have received LentiGlobin DP in Study HGB-205. The median DP cell dose was 8.9 (range 5.6-13.6) $x10^6$ CD34+ cells/kg with a DP VCN of 1.2 (range 0.8−2.1) vector copies/diploid genome. Median post-infusion follow-up was 22.9 months (range 11.6-33.5). All subjects engrafted successfully with median time to neutrophil engraftment of 17 (range 14-38) days. Within patients, VCN in peripheral blood remained generally consistent from Month 3 (range 0.3−3.3 at last measurement). The toxicity profile was consistent with myeloablative conditioning with single-agent busulfan, with no ≥Grade 3 DP-related AEs or serious AEs and no evidence of clonal dominance reported to date. The patient with severe SCD who, prior to study enrollment, received regular RBC transfusions, experienced no clinical symptoms or complications of SCD in the 21 months since treatment. At Month 21, his total Hb was 13.1 g/dL, with 6.2 g/dL HbA^{T87Q} (48%) and 6.5 g/dL sickle Hb (HbS: 50%); in addition, their unconjugated bilirubin, lactate dehydrogenase and reticulocyte count had dropped by 56%, 58%, 26%, respectively, compared to screening. Of the 4 patients with TDT, 3 have β^0/β^E genotypes and 1 is homozygous for a severe β^+ mutation (IVS1 nt 110 G>A). Two of the β^0/β^E patients have completed their 2-year primary follow-up and entered a long-term follow-up study. They have been without RBC transfusions for 33 and 30 months, with total Hb of 10.9 and 13.5 g/dL, and HbA^{T87Q} of 7.7 and 10.1 g/dL, respectively. The third patient with a β^0/β^E genotype has 12 months follow-up and has not required transfusions since 4 days post-LentiGlobin DP infusion, with total Hb 11.3 g/dL and HbA^{T87Q} of 8.6 g/dL. The patient with the IVS1 genotype has 15 months of follow-up and has been free of transfusions for 11.6 months, with total Hb 8.3 g/dL and HbA^{T87Q} of 6.7 g/dL. Since September 2016, 2 more patients with severe SCD have received LentiGlobin DP.
Summary/Conclusions: Data to date from this ongoing Phase 1/2 clinical study suggest that treatment with LentiGlobin DP elicits sustained HbA^{T87Q} levels, which alleviate the clinical and biochemical effects of severe SCD and TDT, with safety consistent with myeloablative conditioning. Follow-up data on the 5 previously reported patients and early results from the 2 recently treated patients will be presented.

Indolent Non-Hodgkin lymphoma - Clinical

P632

A SINGLE INSTITUTIONAL EXPERIENCE OF 261 PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA

M. Van den Bergh[1,*], L. Isenalumhe[1], E. Wang[2], B. Schaible[1], Z. Ma[1], L. Zhang[1], L. Sokol[1]
[1]H. Lee Moffitt Cancer Center & Research Institute, [2]University of South Florida, Tampa, United States

Background: Large granular lymphocytic leukemia (LGLL) is a rare clonal lymphoproliferative disorder of post-thymic T-cell or natural killer (NK)-cell lineage associated with cytopenias, splenomegaly, autoimmune disorders, and recurrent mucocutaneous infections. Treatment is dictated by the presence of these manifestations and consists of immunosuppressive therapy.
Aims: The main aim of this study is to evaluate clinical features, hematological parameters, and survival data of patients with LGLL. The secondary aim is to assess response rates and duration of response to various first line immunosuppressive therapies in LGLL.
Methods: This is a retrospective analysis of clinical and laboratory features, treatment modalities, and outcomes of LGLL patients evaluated at Moffitt Cancer Center between January 1, 1995 and May 1, 2016. Continuous and categorical variables were tested via Kruskal-Wallis ANOVA and Fisher's Exact Test, respectively. Kaplan-Meier curves were used for overall survival (OS). P-values were two-sided with significance set at <0.05.
Results: We identified 261 patients with LGLL (91.6% T-cell, 8.4% NK-cell). Median age was 66 years [21-90] and M:F ratio was 1.2:1. Median follow up was 3.07 years [0-21.88]. 42.9% of LGLL patients presented with anemia, 37.1% with neutropenia, 30.7% with thrombocytopenia, 29.1% with bicytopenia and 6.9% with pancytopenia. Transfusion dependence was noted in 20.3%, splenomegaly in 27.2% and bone marrow involvement in 69.3%. 24.9% had autoimmune diseases and 9.2% had autoimmune cytopenias. 45.6% were observed while the remainder required at least one line of therapy. 5-year and 10-year OS were 75.0% and 63.1%, respectively. There was no statistically significant difference in OS, complete response rate or duration of response based on first line agent (methotrexate, cyclophosphamide, cyclosporine A). However, there was a statistically significant improved partial response with methotrexate *versus* other therapies (p=0.01). A marginally significant association between severe anemia/transfusion dependence and poor overall response rate (p=0.075) to any immunosuppressive therapy was noted. There was no statistically significant difference in OS based on absolute LGL count. Mean number of therapies was 1.08 (range 0-6) and was higher in patients with LGL count <0.5 k/μL (p=0.0078), bone marrow involvement (p<0.0001), and splenomegaly (p<0.0001).
Summary/Conclusions: In this large retrospective study, we described the frequency of LGLL-associated manifestations and their impact on the course of LGLL. Severe anemia/transfusion dependence, lower LGL counts, bone marrow involvement, and splenomegaly were suggestive of more aggressive disease. We confirmed that there is no difference in overall survival among first line immunosuppressive therapies.

P633

ONGOING PHASE 1/2 STUDY OF INCB050465, A SELECTIVE PI3K-DELTA INHIBITOR, FOR THE TREATMENT OF PATIENTS WITH RELAPSED/REFRACTORY B-CELL MALIGNANCIES (CITADEL-101)

A. Forero-Torres[1,*], L.P. Akard[2], M.S. Wertheim[3], T.J. Phillips[4], M.E. Gutierrez[5], J.W. Edenfield[6], P. Caimi[7], J. Call[8], D.O. Persky[9], D.J. DeMarini[10], L. Zhou[10], S. Yeleswaram[11], R. Ramchandren[12]
[1]University of Alabama Birmingham, Birmingham, AL, [2]Indiana Blood & Marrow Transplantation, LLC, Indianapolis, IN, [3]Hematology/Oncology Associates of Treasure Coast, Port St Lucie, FL, [4]University of Michigan, Ann Arbor, MI, [5]Hackensack University Medical Center, Hackensack, NJ, [6]Greenville Health System Cancer Institute, Greenville, SC, [7]Department of Medicine-Gastroenterology, Cleveland, OH, [8]Utah Cancer Specialists-Network, Salt Lake City, UT, [9]University of Arizona Cancer Center, Tucson, AZ, [10]Incyte Corporation, Wilmington, DE, [11]Incyte Corporation, Wilmington, [12]Karmanos Cancer Center, Detroit, MI, United States

Background: Signaling networks mediated by PI3Kδ have been implicated in proliferation, migration, and functioning of B-cells. INCB050465 is a novel, potent, and selective inhibitor of PI3Kδ (≥19,000-fold more selective for PI3Kδ *vs* other isoforms). INCB050465 demonstrated linear pharmacokinetics (PK) and achieved exposure levels several-fold greater than the IC_{90} for PI3Kδ inhibition at the recommended phase 2 dose (ASH 2016; Abstract 4195).
Aims: To evaluate INCB050465 in patients with relapsed or refractory B-cell malignancies enrolled in an ongoing phase 1/2 study (NCT02018861)
Methods: In this phase 1/2 study, eligible patients (≥18 years of age) had relapsed/refractory lymphoid B-cell malignancies (excluding Burkitt's lymphoma and precursor B-cell lymphoblastic leukemia/lymphoma), Eastern Cooperative Oncology Group performance status score ≤2 (≤1 during dose escalation), normal liver and kidney function, and had not received autologous hematopoietic stem-cell transplant (HSCT) within 3 months or allogeneic HSCT within 6 months of screening. The protocol was initiated with a single-patient cohort, treated with oral INCB050465 5mg QD. Subsequent cohorts used a 3+3 design and evaluated doses of 10–45mg QD. Based on PK/pharmacodynamics, the 20 and 30mg QD cohorts were expanded. Responses were assessed every 9 weeks using the Lugano Classification or International Working Group on Chronic Lymphocytic Lymphoma (CLL) criteria.
Results: As of the data cutoff (Nov 1, 2016), 52 patients were treated (median age, 65 years [range, 30–88]). Baseline disease subtypes included diffuse large B-cell lymphoma (DLBCL; n=14), follicular lymphoma (FL; n=10), Hodgkin lymphoma (HL; n=9), marginal zone lymphoma (MZL; n=8), CLL (n=6), and mantle cell lymphoma (MCL; n=5). Sixty-two percent (n=32) of patients had ≥3 prior systemic regimens; 31% (n=16) had prior HSCT. Median duration of therapy was 3.3 months (range, 0.6–13.4); no DLTs were identified. Sixty-seven percent of patients discontinued therapy, most commonly due to disease progression (31%) and AEs (25%). Thirty-three percent of patients had dose interruption and 4% had dose reduction. Most common nonhematologic AEs (all grade; grade ≥3) were nausea (38%; 0%), diarrhea (31%; 6%), and vomiting (25%; 0%). Grade ≥3 hematologic AEs included neutropenia (21%), lymphopenia (17%), thrombocytopenia (10%), and anemia (4%). Forty-percent of patients had serious AEs (SAEs), most frequently colitis, diarrhea, and hypotension (all n=3). One patient had grade 3 pneumonitis; none had *Pneumocystis jirovecii* pneumonia (PJP) or grade ≥2 elevated transaminase. Objective responses occurred at all doses (**Table 1**), except 5mg QD; 90% of the objective responses were observed at the 9-week disease assessment.

Table 1.

	N[a]	Objective Response, n (%)	Complete Response,[b] n	Partial Response,[b] n
NHL	31	19 (61)	10	9
DLBCL	14	5 (36)	3	2
FL	9	7 (78)	2	5
MZL	4	4 (100)	2	2
MCL	4[c]	3 (75)	3	0
CLL	6[c]	2 (33)	0	2
HL	8	1 (13)	0	1

[a]7 patients were not evaluable for response because they had not reached a postbaseline assessment as of the data cutoff date.
[b]Radiologic/metabolic.
[c]1 patient with MCL and 3 with CLL had previously received ibrutinib; among these 4 patients, 1 objective response (partial response in CLL) was observed in this study.

Summary/Conclusions: In patients with relapsed/refractory B-cell malignancies, INCB050465 demonstrated manageable toxicities with no clinically meaningful transaminitis or PJP. Objective response rates were generally high and most responses (90%) were observed at the 9-week disease assessment. Different dosing regimens/schedules, long-term safety, and disease-specific cohorts are being evaluated.

PHASE IIIB RANDOMIZED STUDY OF LENALIDOMIDE PLUS RITUXIMAB (R2) FOLLOWED BY LENALIDOMIDE VS. RITUXIMAB MAINTENANCE IN PATIENTS WITH RELAPSED/REFRACTORY NHL: ANALYSIS OF FOLLICULAR LYMPHOMA PATIENTS

J.M. Burke[1,2,*], D.J. Andorsky[2,3], A. Yacoub[4], J. Melear[2,5], M. Coleman[6], K. Kolibaba[2,7], H. Brooks[2,8], J. Bitran[9], S. Fanning[10], F. Lansigan[11], J.L. Ricker[12], K. Foon[12], M. Llorente[12], J. Li[12], J. Sharman[2,13]
[1]Rocky Mountain Cancer Centers, Aurora, CO, [2]The US Oncology Network, The Woodlands, TX, [3]Rocky Mountain Cancer Centers, US Oncology Research, Boulder, CO, [4]University of Kansas Cancer Center, Westwood, KS, [5]Texas Oncology, Austin, TX, [6]Weill Cornell Medicine, New York, NY, [7]Northwest Cancer Specialists PC, Vancouver, WA, [8]Oncology and Hematology Associates, US Oncology Research, Roanoke, VA, [9]Oncology Specialists, SC, Park Ridge, IL, [10]Greenville Health System, Greenville, SC, [11]Dartmouth Hitchcock Medical Center, Lebanon, NH, [12]Celgene Corporation, Summit, NJ, [13]Willamette Valley Cancer Institute and Research Center, US Oncology Research, Springfield, OR, United States

Background: Lenalidomide is an immunomodulatory agent with direct and immune-mediated mechanisms of action, and clinical activity in indolent non-Hodgkin lymphoma (NHL). Recent studies in frontline and relapsed/refractory (R/R) iNHL show tolerability and high activity for the combination of lenalidomide plus rituximab (R^2) and support further study of R^2.
Aims: The current study evaluates the efficacy and safety of R^2 induction in patients with R/R follicular lymphoma (FL).
Methods: MAGNIFY (NCT01996865) is a Phase IIIb, multicenter, open-label study of R/R NHL patients, including grades 1-3b and transformed follicular

lymphoma (tFL). Upon informed consent, patients receive 12 cycles of R^2 induction (lenalidomide 20mg/d, 21 of 28 d; rituximab 375mg/m^2 weekly cycle 1 [d1, 8, 15, 22], then d1 of odd cycles). Responders to induction (≥SD) are randomized 1:1 to maintenance with either R^2 or rituximab alone (18 cycles); following R^2 maintenance, optional single-agent lenalidomide (10mg/d, 21 of 28 d) can be given until PD. The primary endpoint is progression-free survival (PFS).

Results: As of April 14, 2016, 106 patients with R/R FL have been enrolled, including 103 with grade 1-3a FL, 2 with tFL, and 1 unknown grade. Median age of patients with FL was 66 y (range, 41-91); most had ECOG PS of 0-1 (99%) and stage III/IV disease at study entry (80%). Patients received a median of 2 prior therapies (>2, 30%); 103 (97%) patients had received prior rituximab-containing treatment, of which 35% were rituximab refractory (defined as best response of SD/PD to rituximab/rituximab-containing regimen or a CR/PR of <6 mo after the last rituximab dose). The most common prior regimens were rituximab alone (40%), R-CHOP/R-CHOP–like (38%), and bendamustine plus rituximab (35%). Premature discontinuation of lenalidomide and/or rituximab occurred in 39 (37%) patients during the induction period, mainly due to AEs (n=20); the most common treatment-related AE leading to early discontinuation in the induction period was neutropenia in 6 patients. Four (4%) patients discontinued the study. Common grade 3/4 treatment-emergent AEs during induction in the FL safety population (n=104) were 27% neutropenia, 7% leukopenia, and 6% fatigue. At a median induction duration of 23 weeks (range, 0.4-51), 83 FL patients were evaluable for response with an overall response rate (ORR) of 65%; those who were not rituximab refractory had improved ORR compared to rituximab-refractory patients (70% *vs* 55%; Table 1). The median time to response during induction was 2.8 mo. Twenty patients have completed 12 cycles of induction and 16 proceeded to maintenance (n=6 R^2, n=10 rituximab alone). Enrollment is ongoing.

Table 1.

Table 1. Best response during R^2 induction in evaluable patients with R/R NHL

Response status, n (%)	FL* (n=83)	Not Rituximab-Refractory (n=54)	Rituximab Refractory (n=29)
ORR	54 (65)	38 (70)	16 (55)
95% CI	54%-75%	56%-82%	36%-74%
CR/CRu	31 (37)	21 (39)	10 (34)
PR	23 (28)	17 (31)	6 (21)
SD	22 (27)	13 (24)	9 (31)
PD†	7 (8)	3 (6)	4 (14)

*Includes 1 patient with tFL. †PD or death prior to completion of response evaluation.

Summary/Conclusions: R^2 induction therapy shows favorable activity and a tolerable safety profile in patients with advanced-stage, R/R FL. The study is ongoing to determine the effect of R^2 *vs* rituximab maintenance in FL patients, and updated results will be presented.

P635

A DOUBLE-BLIND, RANDOMIZED PHASE 3 STUDY TO COMPARE EFFICACY AND SAFETY OF CT-P10 TO INNOVATOR RITUXIMAB IN COMBINATION WITH CVP IN PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED FOLLICULAR LYMPHOMA

Blokhin Russian Cancer Research Center, Moscow, Russian Federation, [15]Celltrion Inc., Incheon, Korea, Republic Of

Background: CT-P10 is the first biosimilar of innovator rituximab (RTX), approved for all indications by the European Medicines Agency. CT-P10 has demonstrated pharmacokinetics (PK) and efficacy equivalence in patients with rheumatoid arthritis (Yoo, ACR 2016) and PK equivalence in patients with advanced follicular lymphoma (AFL) (Coiffier, ASH 2016).

Aims: This study aimed to demonstrate non-inferiority (NI) of efficacy and PK equivalence between CT-P10 and RTX in patients with newly diagnosed advanced follicular lymphoma (AFL) (NCT02162771).

Methods: A total of 140 patients were randomized in a 1:1 ratio to receive CT-P10 or RTX (375mg/m^2 intravenous) plus CVP (cyclophosphamide, vincristine, and prednisone) therapy every 3 weeks over 8 cycles. Overall response rate (ORR) based on best overall response over 24 weeks was assessed by the independent review committee, according to the 1999 International Working Group criteria.

Results: Therapeutic NI of CT-P10 to RTX has been demonstrated in terms of ORR over 8 cycles (Table 1). The ORR difference between two treatment groups was 4.3% in per-protocol (PP) population and 5.7% in intent-to-treat (ITT) population. Considering the statistical Non-Inferiority test using confidence interval (CI) approach with the exact binomial CI for the difference of ORR between two treatment groups, the lower bound of 95% CI lies on the positive side of -7% NI margin (-4.25% in PP population and -3.41% in ITT population). The pre-defined non-inferiority criterion has been met with the descriptive point estimate difference approach and the formal statistical NI test with a 5% significance level. Median number of B-cells decreased to the lower limit of quantification (LLoQ) after the 1st infusion and remained at the LLoQ over 8 cycles in both groups. Overall safety profile of CT-P10 was consistent with that of RTX (Table 2). No progressive multifocal leukoencephalopathy or Hepatitis B virus reactivation were reported in either groups. The proportion of patients with positive anti-drug antibody were similar between both groups (4.3% and 2.9%) over 24 weeks in the induction period.

Table 1. Summary of Efficacy [Number (%) of patients].

PP population	CT-P10 (N=66)	RTX (N=68)	Difference* [lower bound of 95% CI]
ORR (CR+CRu+PR)	64 (97.0)	63 (92.6)	4.3% [-4.25%]
Complete response (CR)	20 (30.3)	15 (22.1)	
Unconfirmed CR (CRu)	6 (9.1)	8 (11.8)	
Partial response (PR)	38 (57.6)	40 (58.8)	

** Difference was calculated using percentages not the round off values.*

Table 2. Summary of Treatment-emergent adverse event (TEAE) related to the study drug [Number (%) of patients].

Safety population	CT-P10 (N=70)	RTX (N=70)	P-value (Fisher's exact test)
TEAE	37 (52.9)	34 (48.6)	0.7354
Serious TEAE	6 (8.6)	4 (5.7)	0.7447
Infusion-related reaction	15 (21.4)	17 (24.3)	0.8407
Infection	6 (8.6)	9 (12.9)	0.5861

Summary/Conclusions: This study demonstrates therapeutic non-inferiority of CT-P10 to RTX combined with CVP therapy in previously untreated AFL. CT-P10 was well-tolerated and the safety profile including immunogenicity of CT-P10 was comparable to that of RTX over 8 cycles in induction period.

P636

DURABLE DISEASE CONTROL OF EARLY MYCOSIS FUNGOIDES PATIENTS TREATED WITH LOW-DOSE INTERFERON-ALPHA2B AND PUVA

S. Rupoli[1,*], G. Goteri[2], G. Micucci[1], I. Federici[1], L. Canafoglia[1], F. Giantomassi[2], I. Cataldi[3], A. Giacchetti[4], G. Tucci[4], L. Morresi[4], A. Bettacchi[5], M. Nicolini[6], A. Cellini[3], G. Lemme[3], A.M. Offidani[3], P. Leoni[1]
[1]Clinica di Ematologia, [2]Istituto di Anatomia Patologica, [3]Clinica di Dermatologia, Ospedali Riuniti Umberto I- Salesi-Lancisi di Ancona, [4]Clinica di Dermatologia, I.N.R.C.A. Ancona, ancona, [5]Clinica di Dermatologia, Ospedale di Macerata, Macerata, [6]Clinica di Dermatologia, Ospedale di Jesi, Jesi, Italy

Background: Early stage Mycosis Fungoides (MF) has an indolent, relapsing course, with patients frequently undergoing multiple therapies. Current guidelines consider the utility of combination therapies (skin-directed therapies plus systemic biologic response modifiers) to increase the therapeutic efficacy. Recently, time to next treatment (TTNT) was applied as a new relevant measure of the durability of response of PUVA, interferon-alpha (IFN-α) and retinoids as monotherapies in early MF (Hughes et al, *Blood 2015*; Hanel et al, *AJH 2016*), but it has not been yet investigated in combination therapies.

Aims: We aimed to evaluate TTNT together with the usual time-to-event measures (OS and EFS) in the series of 89 early MF patients treated for 14 months with low-dose IFN-α2b (6-18 MU weekly) and PUVA, which was first reported in 2005 (Rupoli et al, *EJH 2005*). The follow-up was prolonged up to October 2016, in order to evaluate prospectively the regimen activity and influence on the further course of the disease.

Methods: The design, rationale, safety and efficacy results for this protocol were previously published. Clinical stages IA-IIA patients who had received no previous treatment, or had been submitted to a 4-month wash-out after systemic therapy or a 4-week wash-out after topical therapy, were included in the study. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

Results: Eighty-nine patients (56 men and 33 women) with a median age of 60 years (range, 17-80) were recruited. Disease stage was IA in 22 patients, IB in 55, IIA in 11, and IIB in 1 patient. The majority of patients had generalized skin disease (75% T2 *vs* 25% T1). The protocol proved to be highly effective, well tolerated and able to induce complete clearing of skin lesions in 84% of patients and an overall response in 98%. The median follow-up time was 175 months (range 4-259). Updated data showed that the median overall survival (OS) was not reached, whilst the median event-free survival (EFS) was 142 months (95% C.I. 130-153). Estimated OS rates at 1, 2, 5, 10, 15 and 20 years

were 99%, 98%, 92%, 89%, 78% and 51%; at 1, 2, 5, 10, 15 and 20 years 98%, 97%, 88%, 67%, 19%, 0%, were free from events. Median TTNT was not reached thus indicating clinical benefit with IFN-α and PUVA. Kaplan-Meier estimated rates of 97% at 1 year, and 91% at 2 years, respectively whereas 5-, 10-, 20-year TTNT remained almost unchanged with 62% of patients that still had not required further treatment.

Summary/Conclusions: There has been an ongoing debate about whether patients would benefit from adding PUVA to IFN-α in the treatment of early stage MF. We chose to initiate the combination treatment of MF as early as possible in the course of the disease to induce a permanent remission or even a *cure*. In our experience, this regimen set the realistic goal of achieve high rates of complete clearing and durable responses (median TTNT not reached) with only 38% of patients requiring a subsequent systemic treatment within 20 years. Here, we suggest a synergistic or additive effect between PUVA and IFN-α compared with either agent alone. With respect to Hughes et al, (*Blood 2015*), our combination treatment provide a longer TTNT than PUVA or IFN-α monotherapy (36.3 months and 8.7 months respectively). At 2 years, 91% of patients receiving PUVA plus IFN-α were free from further treatment as compared to 54.2% and 29.1% treated with PUVA or IFN-α monotherapy, respectively.

Feliciano[13], Y. Wang[13], M.C. Palanca-Wessels[13], A. Gautam[1], Y. Zhu[1], H.-M. Lin[1], Y. Liu[1], M. Little[1], M.R. Dalal[1,*]
[1]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, [2]The University of Melbourne, Victoria, Australia, [3]Guys and St Thomas NHS Foundation Trust, London, United Kingdom, [4]Memorial Sloan Kettering Cancer Center, New York, [5]The University of Texas MD Anderson Cancer Center, Houston, [6]Stanford University School of Medicine and Stanford Cancer Institute, California, United States, [7]University Hospital Zürich, Zürich, Switzerland, [8]University Hospital Birmingham, Birmingham, United Kingdom, [9]University of Turin, Turin, [10]University of Bologna, Bologna, Italy, [11]University Hospitals Leuven, Leuven, Belgium, [12]Columbia University, New York, [13]Seattle Genetics, Inc., Bothell, United States

Background: CTCL is a generally incurable, relapsing disease associated with a significant symptom burden, including disfiguring lesions, debilitating pruritus and frequent skin infections. ALCANZA is a Phase 3 study of BV *vs* PC (MTX or Bex) for the treatment of CD30-positive (CD30+) CTCL (NCT01578499). BV was associated with significantly improved rate of objective response lasting ≥4 months (ORR4; 56% *vs* 13%; p<0.0001), longer median progression-free survival (PFS; 16.7 *vs* 3.5 months; p<0.0001), and decreased symptom burden measured by Skindex-29 (27.96 *vs* -8.62; p<0.0001), compared with PC. BV's safety profile was consistent with previous reports, with all-grade and grade 3 peripheral neuropathy of 67% and 9%, respectively. Number needed to treat (NNT), defined as the number of patients (pts) that need to be treated to prevent one outcome event relative to the comparator therapy, is an effective method to assess the benefit-risk of BV in a clinically relevant manner. NNT values of 3–28 have been previously reported, at various time points, in hematologic malignancies (multiple myeloma, B-cell non-Hodgkin lymphoma) to prevent one disease progression event or death. Data from the Phase 3 AETHERA study demonstrated that, at various time points, and dependent on risk group, one in 3–8 Hodgkin lymphoma pts treated with BV consolidation therapy post-autologous stem cell transplant will benefit by avoiding disease progression/death, compared with placebo.

Aims: To determine the NNT with BV to avoid one additional event of disease progression or death compared with PC in the ALCANZA trial.

Methods: The NNT with BV was calculated as the inverse of the absolute risk reduction (ARR); ARR was the PFS event rate per independent review facility (IRF) assessment in the PC arm minus the event rate in the BV arm. PFS was defined as the time from randomization until progressive disease/death due to any cause, counting all events despite two or more missed visits or starting of subsequent anticancer therapy (European Medicines Agency [EMA] criteria). ALCANZA recruited adults (≥18 years) with previously treated CD30+ mycosis fungoides or primary cutaneous anaplastic large cell lymphoma. Pts were randomized 1:1 to receive BV 1.8mg/kg IV, once every 3 weeks, for up to 16 three-week cycles, or PC of MTX 5–50mg PO, once weekly, or Bex 300mg/m² (target dose) PO, once daily, for up to 48 weeks. All pts gave informed consent.

Results: The intent-to-treat (ITT) population comprised 128 pts (median age 60 yrs [range 22–83]; 55% male) who received BV (n=64) or PC (n=64). Fewer PFS events per IRF assessment per EMA criteria were experienced by pts in the BV arm *vs* PC arm (Table). The NNT with BV to prevent a disease progression/death ranged from 2.00 (95% CI 1.59, 3) to 3.76 pts (95% CI 2.5, 8.44) over 24 months (Table). At 24 months, the NNT to prevent a disease progression/death was 3.37 pts (95% CI 2.26, 7.67).

Table 1. NNT analysis per IRF assessment of PFS in the ALCANZA ITT population.

Month	Number of PFS events per IRF analysis		NNT	95% CI
	BV (n=64)	PC (n=64)		
3	7	24	3.76	2.5, 8.44
6	11	42	2.06	1.63, 3.13
9	15	47	2.00	1.59, 3
12	19	47	2.29	1.75, 3.73
15	21	47	2.46	1.84, 4.24
18	29	47	3.56	2.33, 8.99
21	29	48	3.37	2.25, 7.83
24	31	50	3.37	2.26, 7.67

Summary/Conclusions: ALCANZA data suggest that, at various time points, one in every 2–4 pts treated with BV will benefit by avoiding disease progression/death. This further demonstrates BV's clinical benefit in CD30+ CTCL pts requiring systemic therapy. This is, to our knowledge, the first report of an NNT analysis for a treatment in the CTCL setting.

P638

PRIMARY OCULAR ADNEXAL LYMPHOMA OF ALL HISTOLOGIC SUBTYPES: SURVIVAL OUTCOMES AND RISK FACTORS IN LARGE COHORT OF PATIENTS AND LONG-TERM FOLLOW-UP

Y.-W. Jeon[1,*], S.-S. Park[1], J.-H. Yoon[1], S.-E. Lee[1], K.-S. Eom[1], Y.-J. Kim[1], H.-J. Kim[1], S. Lee[1], C.-K. Min[1], J.-W. Lee[1], W.-S. Min[1], S.-G. Cho[1]
[1]Department of Hematology, St.Mary Hospital,Seoul, Catholic Medical Center, Seoul, Korea, Republic Of

Background: Although the recent reports show that interest in ocular adnexal lymphomas (OAL) and their biologic and clinical characteristics have been increased, the most OAL-related clinical study is still limited in the small number with insufficient follow-up period, result in retrospective studies with non-reproducible. Moreover, because the majority of OAL were in the low-grade histologic subtypes as primary ocular adnexal MALT (mucosa-associated lymphoid tissue) lymphoma, there is few comparative analysis study of all histologic subtypes in OAL patients especially for non-MALT type OAL in large cohort OAL.

Aims: So our purposes of this study were to identify a correlation between histopathological diagnosis and significant parameters associated with clinical outcomes of patients with OAL in patients with diverse histologic subtypes.

Methods: We evaluated the consecutive 207 primary OAL patients who diagnosed at Catholic University Lymphoma Group (CULG) of Catholic Bone Marrow Center, Seoul between January 2004 to April 2015. Clinical information and parameters were gathered from the electronic medical records such as geographic status, complete blood count (CBC) with blood chemistry, the status of BM involvement, primary therapeutic modalities, response to initial therapy, and treatment-related complications with survival outcomes.

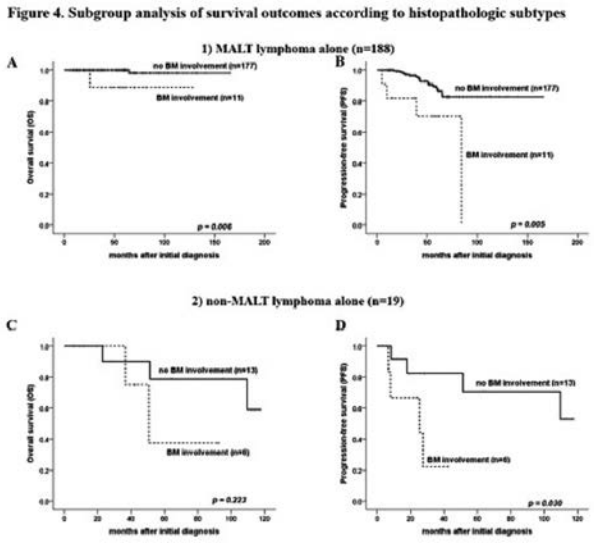

Figure 1.

Results: In OAL of all histologic subtypes, 10-year lymphoma-specific OS and PFS were 89.3% and 71.0% respectively. 182 patients achieved CR (87.9%). CR rate according to primary therapy was 90.4% (n=103) in T1N0M0, 95.2% (n=40) in T2N0M0, 100% (n=7) in T3N0M0, 83.3% (n=5) in T4N0M0, and 71.1% (n=27) in TxN1-4M0/ TxNxM1. Multivariate analysis in OAL of all histologic subtypes showed that the risk factors-associated PFS were positivity of BM involvement and non-MALT lymphoma subtype (hazard ratio; HR=5.98, *p* <0.001 and HR=2.96, *p*=0.025, respectively), the risk factors-related OS was only non-MALT lymphoma subtype (HR=9.18, *p*=0.013). Then, subgroup analysis

according to histopathologic subtypes, BM involvement alone was regarded as a statistically significant factor in the group of MALT lymphoma (HR=3.99, *p*=0.013) and there were no statistically significant factors in the group of non-MALT lymphoma. Although there were no risk factors with statistical significance, the BM involvement and advanced TNM stage showed a trend toward statistical significance about affecting to the failure of PFS (BM involvement of HR 5.19, *p*=0.054 and advanced TNM stage of HR 3.06, *p*=0.056). The median time-to-progression (TTP) was from 3 to 3.5 years after initial therapy in relapse or dead patients (range from 4.6 to 109.6 months).
Summary/Conclusions: Our study confirmed that OAL of all histologic subtypes also represented the indolent nature and localized behavior with favorable survival outcomes. Although BM involved OAL consisted of a small number, it was associated with poor survival outcomes. Also, relapse and lymphoma-related mortality had long-term delayed TTP, so we suggested that BM biopsy might be a necessary study for initial staging at least in all OAL and long-term follow-up is required for patients with all histologic type of OAL.

P639

CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CBL-MZ): A PROSPECTIVE REGISTRATIONAL STUDY ON 96 CASES

C. Kalpadakis[1,*], G. Pangalis[2], T. Vassilakopoulos[3], S. Sachanas[2], M. Moschogiannis[2], X. Yiakoumis[2], M.-C. Kyrtsonis[4], P. Tsirkinidis[2], A. Dimitrakopoulou[5], P. Korkolopoulou[6], F. Kontopidou[7], E. Koulieris[2], C. Pontikoglou[1], M. Ximeri[1], M. Roumelioti[4], D. Rontogianni[8], H. Papadaki[1], P. Panagiotidis[4], M. Angelopoulou[3]
[1]Department of Haematology, University Hospital, University of Crete, Heraklion, [2]Department of Haematology, Athens Medical Center-Psychikon Branch, [3]Department of Haematology, [4]1st Department of Propedeutics, University of Athens, Laikon General Hospital, [5]Immunology Laboratory, Laikon General Hospital, [6]Department of Pathology, [7]2nd Department of Internal Medicine, University of Athens, [8]Department of Anatomic Pathology, Evangelismos General Hospital, University of Athens, Athens, Greece

Background: Clonal B-cell lymphocytosis of marginal zone origin (CBL-MZ) has been recognized as a provisional entity in the WHO classification. Despite diagnostic similarities with SMZL, the exact relation between them has not been established yet. AIM: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.
Aims: To describe the main features of CBL-MZ and to further elucidate its relation to SMZL.
Methods: 96 CBL-MZ were analyzed. Staging at diagnosis included CBCs, blood morphology and immunophenotype, biochemistry, viral test for hepatitis C and B, serum immunoglobulin levels and immunofixation as well as whole body CT scan. BM biopsies were available in 78 cases which were studied with the following panel of moAbs: CD20, DBA44, CD23, CD5, CD25, CD38, CD27, s/cIgM/D, TCL-1, MNDA, T-bet and IRTA-1. Gastroscopy with multiple biopsies was performed in 56 cases. FISH analysis for del7q was done in 13 pts, and detection for *MYD88* mutation in 60.

Table 1.

Table. Main disease features of 96 CBL-MZ pts

Parameter	# of cases	%
Age (median)(range)	70 (38-87)	
Male sex	47	49
ALC (median)	5098/μL	
Circulating Clonal B-cells (median)	2880/μL	
Paraproteinemia	41/87	47
Del7q	1/13	8
MYD-88	11/60	18
% BM infiltration (median)(range)	30(10-85)	
Clinical course in 90 pts		
Stable	55	61
ALC increase	18	20
Splenomegaly	5	6
Increase of paraproteinemia	6	7
Cytopenias due to extensive BM infiltration	5	6
Lymphadenopathy	1	1
Autoimmune thrombocytopenia	1	1
Regression of lymphocytosis	2	2
2ry neoplasm	4	4
Treatment due to disease progression	9	10
Outcome	2	2
• Toxic death	1	1
• Death from 2ry neo	1	1

Results: A synoptic presentation of the main characteristics of CBL-MZ is given in the table. The median age was 70 y without sex predilection. By definition, no case presented with cytopenia, lymphadenopathy, splenomegaly or any other organ involvement. Median ALC and clonal B-cell counts were 5098/μL and 2880/μL, respectively. 47% had paraproteinemia, mainly of the IgM type. H.pylori (+) gastritis was evident in 30%. Hp eradication had no influence on the lymphocyte counts. The percentage of BM infiltration was highly variable, ranging from 10% to 85%, with an intrasinusoidal pattern in 31%. TCL-1, T-bet, IRTA-1, and MNDA were invariably negative. *MYD-88* mutation was detected in 18% and was significantly associated with IgM paraproteinemia. 6 cases were lost to follow-up. At a median follow-up time of 41 months, the majority of the cases had no disease progression (90%): 61% had stable CBCs, 20% solely an increase in ALCs and 7% an increase in paraproteinemia only, while in 2% lymphocytosis regressed. A total of 9 (10%) pts progressed and required treatment: 5/9 due to cytopenias caused by extensive BM infiltration without splenomegaly, 1 due to bulky splenomegaly,1 due to lymphadenopathy,1 developed autoimmune thrombocytopenia, while in one due to high IgM levels in a MYD-88(-) case. A total of 5 (6%) pts developed splenomegaly after a median time of 78 mos (48-151).
Summary/Conclusions: After a median follow up time of 4y we demonstrated that CBL-MZ, although displaying many diagnostic similarities with SMZL, it rarely evolves to it. Most cases remain stable, while few develop cytopenias due to an extensive BM infiltration. These latter cases apparently represent a distinct MZL category which requires further investigation.

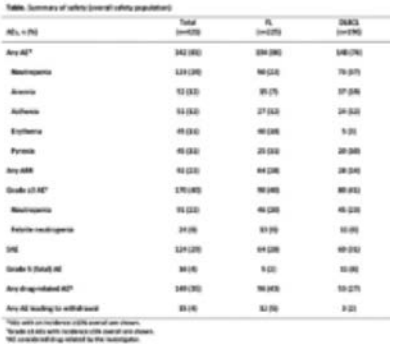
P640

SAFETY OF SUBCUTANEOUS ADMINISTRATION OF RITUXIMAB DURING THE FIRST-LINE TREATMENT OF PATIENTS WITH NON-HODGKIN LYMPHOMA: THE MABRELLA STUDY

C. Panizo[1,*], M.A. Bekadja[2], B. Meddeb[3], O. Meier[4], R. Smith[4], M. Truman[5], C. Baratè[6]
[1]Clínica Universidad de Navarra, Pamplona, Spain, [2]University Hospital Establishment, Oran, Algeria, [3]Aziza Othmana University Hospital, Tunis, Tunisia, [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [5]F. Hoffmann-La Roche Ltd, Dee Why, Australia, [6]University of Pisa, Pisa, Italy

Background: Intravenous (IV) rituximab is the mainstay of treatment for CD20+ B-cell non-Hodgkin lymphoma (NHL). A subcutaneous (SC) formulation of rituximab has been approved in Europe and other countries that reduces healthcare resource burden and improves patient (pt) satisfaction and convenience compared with rituximab IV. MabRella is a global umbrella study comprising three local open-label, single-arm, Phase IIIb studies of rituximab SC, which share a core protocol and primary endpoint but have flexibility for exploratory endpoints (NCT01889069; NCT01987505; NCT02406092). Data from participating countries are pooled for predefined global analyses.
Aims: To evaluate the safety of first-line (1L) rituximab SC in follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL) with a focus on administration-related reactions (ARRs).
Methods: Eligible pts were aged 18–80 years with grade 1–3a FL/DLBCL and ECOG performance status ≤3. All pts had received ≥1 full dose of rituximab IV as 1L induction/maintenance before study entry, and were expected to receive ≥4 additional induction cycles (FL/DLBCL) or ≥6 additional maintenance cycles (FL). Informed consent was obtained. For induction, pts received rituximab SC 1400mg every cycle (14, 21 or 28 days) for 4–7 cycles, plus standard chemotherapy. FL pts undergoing maintenance treatment received single-agent rituximab SC 1400mg every 2 months for 6–12 cycles. The primary endpoint was incidence of ARRs, *i.e.* all adverse events (AEs) occurring within 24 hours of administration, considered related to study drug by the investigator. Secondary endpoints included grade ≥3 AEs and serious AEs (SAEs). The safety analysis included all pts who received ≥1 dose of study treatment. Safety data were not collected for rituximab IV, as pts entered the trial after switching to SC. Updated data are presented (data cut-off February 7, 2017).

Table 1.



Results: The safety population comprised 421 pts: 160 Italy; 140 Spain; 121 North Africa (Tunisia, Morocco and Algeria). Median age was 58 years (range 19–80); 49% of pts were male; 225 pts had FL and 196 had DLBCL. Of the pts with FL, 97 completed ≥1 cycle of rituximab SC induction (45 completed 7 cycles) and 204 completed ≥1 cycle of maintenance (175 completed 6 cycles;

73 completed 12 cycles). Among DLBCL pts, 99 completed 7 cycles of induction. Overall, 342 pts (81%) experienced an AE during treatment (Table). Common AEs (≥10% of pts) were neutropenia, anemia, asthenia, erythema and pyrexia. ARRs were observed in 92 pts (22%); the most common (≥2% of pts) were erythema (10%), injection-site erythema (4%), neutropenia (3%) and leukopenia (2%). Grade ≥3 AEs occurring in ≥5% of pts were neutropenia (22%) and febrile neutropenia (6%). Grade ≥3 ARRs were observed in 4 pts (1%). SAEs were reported in 29% of pts (7% drug-related). Of 16 grade 5 (fatal) AEs, 2 were considered related to treatment (*Klebsiella* infection and sepsis). The safety profile of rituximab SC was generally comparable between FL and DLBCL, although neutropenia and anemia (any grade) were more prevalent in DLBCL pts, and erythema (any grade) was more common in FL pts. The AE profile in FL pts was similar during induction and maintenance, but the intensity and seriousness of events was lower during maintenance.
Summary/Conclusions: In line with previous reports, rituximab SC is well tolerated during the 1L treatment of pts with NHL. The safety profile of 1L rituximab SC is similar to reports for IV administration, with the exception of an expected increase in ARRs, the majority of which are mild or moderate in intensity, and resolve spontaneously.

P641

REAL-WORLD EXPERIENCE WITH RITUXIMAB-FLUDARABINE (RF) AND DEXAMETHASONE, RITUXIMAB, CYCLOPHOSPHAMIDE (DRC) IN WALDENSTROM MACROGLOBULINEMIA : A RETROSPECTIVE STUDY FROM 163 PATIENTS

C. Protin[1,*], L. Oberic[1], P. Bories[2], G. Laurent[1], F. Despas[3], L. Ysebaert[1]
[1]Hematology, [2]Oncomip regional cancer network, IUC Toulouse-Oncopole, [3]Clinical Pharmacology, University of Toulouse, Toulouse, France

Background: symptomatic Waldenstrom macroglobulinemia (WM) may be managed with various regimens. After the 8th IWWM congress, experts recommended the use of rituximab-based regimens. Two phase II trials supported DRC (n=72, 1L) and RF (n=43, one-third having received chlorambucil alone, +/- steroids/rituximab before), with published long-term follow up of 95 and 40 months, respectively. Mature data from larger cohorts confirming trials' results in real-life practice are lacking.
Aims: Mature data from larger cohorts confirming trials' results in real-life practice are lacking. Indeed, outside clinical trials, patients are older and experience potentially more long term side effects.
Methods: We report data from a retrospective study in 163 symptomatic WM treated as first-line treatment (or second-line after chlorambucil, n=47) with RF (n=56) or DRC (n=108) between January 01, 2005 and december 31, 2015.
Results: Median follow up for the entire cohort is 5 years, median age at diagnosis 68.6y and at therapy 71.2y, 75% being above 65y at treatment. Significant differences between DRC/RF cohorts were: median age 74/64y, high IPSS score 63%/26%, B2M>3mg/l 74%/56%. *DRC cohort:* median PFS/Time To Next Therapy and Overall Survival were 33mo, 45.8mo and 78% at 5 years, respectively. Dose reductions>20% had no impact on these outcomes, but age>65y and anemia<11.5g/dl decreased PFS. Previous CLB therapy increased the risk for delayed toxicities (infections 39% *vs* 16%, myelodysplasia 13% *vs* 3.8%), but not second cancers including Richter transformation. IPSS scoring system predicted PFS and OS with good accuracy. *RF cohort:* median PFS/Time To Next Therapy and Overall Survival were 53mo, 65mo and 90% at 5 years, respectively. Previous CLB had no impact on outcomes, but dose reductions>20% adversely impacted TTNT. IPSS scoring system did not improve prognostication. Long-term follow-up: 22% of patients had second solid cancers. RF significantly increased the risk of Richter, and CLB exposure the risk of myelodysplasia. Second PFS upon salvage (PFS2) was available in 72 patients: 47 DRC (PFS2 47mo), and 25 RF (PFS2 66mo), not significantly different. Only two parameters decreased the duration of PFS2 with immunochemotherapy: anemia and B2M>3mg/l, suggesting future trials should focus on this subgroup to challenge standard R-based regimens with ibrutinib.
Summary/Conclusions: We conclude that clinical trials results of DRC and RF are reproduced in our real-life cohort despite older ages, and high IPSS scores. Long-term toxicities are also seen, at similar rates and second cancers monitoring should be part of physician's practice in these WM patients.

Infectious diseases, supportive care

MICAFUNGIN *VERSUS* LIPOSOMAL AMPHOTERICIN B FOR EMPIRICAL ANTIFUNGAL THERAPY IN FEBRILE NEUTROPENIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A RANDOMIZED CONTROLLED TRIAL

T. Oyake[1,*], N. Sugawara[1,2], Y. Fujisawa[1,3], R. Sasaki[2,3], W. Izumida[1,4], T. Mine[5], M. Asahi[1], Y. Suzuki[1], Y. Okano[1], Y. Fujishima[1], Y. Tsukushi[1,3], Y. Aoki[1], S. Kowata[1], I. Hanamura[6], K. Murai[7], S. Ito[8], Y. Ishida[1]
[1]Department of Hematology and Oncology, Internal Medicine, Iwate Medical University School of Medicine, Morioka, [2]Division of Hematology, Department of Internal Medicine, Iwate Prefectural Chubu Hospital, Kitakami, [3]Division of Hematology, Department of Internal Medicine, Hachinohe Red Cross Hospital, Hachinohe, [4]Division of Hematology, Department of Internal Medicine, Iwate Prefectural Ohfunato Hospital, Ohfunato, [5]Division of Hematology, Department of Internal Medicine, Morioka Red Cross Hospital, Morioka, [6]Division of Hematology, Department of Internal Medicine, Aichi Medical University School of Medicine, Nagakute, [7]Division of Hematology, Department of Internal Medicine, Iwate Prefectural Central Hospital, [8]Department of Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: Invasive fungal infections (IFIs) incur significant morbidity and mortality in neutropenic patients with hematological malignancies (HEM) after chemotherapy. The risk for these infections is related to the intensity and duration of neutropenia, and varies from 2% to 40%. Mortality rates associated with documented IFIs are considerable, reportedly ranging from 30% to 60%. Empirical antifungal therapy is the standard care for neutropenic patients with HEM, who remain febrile despite broad-spectrum antibacterial treatment. Several antifungal agents including voriconazole (VRCZ) or liposomal amphotericin B (L-AMB) have been studied as empirical therapy for febrile neutropenia (FN). However, limited data are available concerning the efficacy and safety of micafungin (MCFG) in FN patients with HEM.
Aims: We conducted a randomized, cooperative group, open-label trial comparing MCFG (150mg once daily) with L- AMB (2.5mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of HEM.
Methods: 138 hospitalized FN patients with persistent fever of HEM (AML 78, APL 4, ALL 13, MDS (RAEB) 7, NHL 28, MM 5, other hematological malignancy 3 cases) were randomized to each drug group (MCFG, 72; L-AMB, 66). The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).
Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 13.8 and 16.4 days, respectively. The efficacy rates of MCFG and L-AMB were not significantly different (38/72 cases (52.8%) *vs* 26/66 cases (39.4%), p=0.115*), evaluated based on: (1) successful treatment of baseline fungal infection (3/4 cases (75.0%) *vs* 0/1 case (0%), p=0.170*), (2) absence of breakthrough fungal infection (65/72 cases (90.3%) *vs* 65/66 cases (98.5%), p=0.112*), (3) survival for ≥7 days after study completion (66/72 cases (91.7%) *vs* 59/66cases (89.4%), p=0.855*), (4) absence of premature study drug discontinuation due to poor efficacy or drug-related adverse events (54/72 cases (75.0%) *vs* 47/66 cases (71.2%), p=0.615*), and (5) resolution of fever during neutropenia (45/72 cases (62.5%) *vs* 33/66 cases (50.0%), p=0.258*). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (1/72 cases (1.4%) *vs* 9/66 cases (13.6%), p=0.006*). In safety evaluation, adverse events of creatinine increase and hypokalemia were less often in the MCFG group than in the L-AMB group (6/72 cases (8.3%) *vs* 19/66 cases (28.8%), P=0.001*, 14/72 cases (19.4%) *vs* 34/66 cases (51.5%), P=0.0001*). *: Chi square test.
Summary/Conclusions: MCFG was as effective as L-AMB, and better tolerated than L-AMB as an empirical antifungal therapy in FN patients with HEM.

P643

ANTIFUNGAL DRUGS INFLUENCE NEUTROPHIL EFFECTOR FUNCTIONS IN VITRO AND MODULATE PULMONARY DAMAGE IN INVASIVE ASPERGILLOSIS

F. Ries[1], A. Hasibeder[1], P. Aranda Lopez[1], M. Theobald[1], H. Schild[2], M. Radsak[1], D. Teschner[1,*]
[1]Department of Hematology, Medical Oncology, & Pneumology, [2]Institute of Immunology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany

Background: Antifungal agents like azoles, echinocandins or polyenes substantially contribute to reduced morbidity and improved survival of high risk patients in hematology. However, besides their well-known antifungal activity there is a growing body of evidence for immunomodulatory side effects on different effector cells of the immune system.

Aims: The aim of our study is to clarify the immunomodulatory capacity of different antifungal drugs on the effector functions of polymorphonuclear neutrophils (PMN) and on the clinical course of invasive pulmonary aspergillosis (IPA).
Methods: Firstly, isolated PMN from healthy donors were preincubated with different antifungals *in vitro*. Here, we used the azoles fluconazole (FLU), voriconazole (VOR), posaconazole (POS), and isavuconazole (ISA), as well as the echinocandins caspofungin (CAS) and micafungin (MIC), and the polyenes amphotericin b (AmB) and liposomal amphotericin b (LAmB). Furthermore, PMN were simultaneously stimulated with lipopolysaccharides (LPS) or zymosan. Afterwards, PMN were analyzed by flow cytometry regarding activation, degranulation, and phagocytosis. Additionally, a dichlorofluorescein assay was used to detect reactive oxygen species (ROS). IL-8 synthesis was measured by enzyme-linked immunosorbent assay (ELISA). Secondly, a murine model was used to investigate the influence of MIC and POS on the clinical course of IPA *in vivo*. Therefore, mice were treated with antifungals and inoculated intratracheally with A. fumigatus conidia. Afterwards, mice were analyzed concerning fungal burden and pulmonary damage (albumin ELISA) with neutropenic animals serving as controls.
Results: *In vitro*, pretreatment with POS lead to enhanced activation (CD62L: 44% +/- 8 *vs* 13 +/- 2, *; mean +/- SEM; p value ≤0.05 considered to be significant [*]), increased degranulation, and intensified generation of ROS (26880 rfu +/- 2834 *vs* 8528 +/- 161, *), whereas zymosan triggered IL-8 synthesis was reduced by trend. In contrast, ISA pretreated PMN showed decreased expression of activation markers. Moreover, ISA impaired degranulation and LPS triggered generation of ROS (6980 rfu +/- 1338 *vs* 28730 +/- 6893, *). FLU and VOR did not show a significant influence on PMN effector functions *in vitro*. MIC pretreatment resulted in enhanced expression of activation marker CD62L but reduced expression of CD11b, and decreased degranulation. Additionally, phagocytosis (27% +/- 4 *vs* 44 +/- 1, LPS, *) as well as generation of ROS (22660 rfu +/- 3286 *vs* 41190 +/- 2584, zymosan, *), and IL-8 synthesis were substantially impaired. CAS showed an increased phagocytosis (75% +/- 6 *vs* 44 +/- 5, LPS, *), whereas degranulation and LPS triggered generation of ROS were reduced by trend. Pretreatment with conventional AmB resulted in activation of almost all effector functions besides impaired phagocytosis (43% +/- 3 *vs* 59 +/- 3, LPS, *). In contrast, LAmB did not significantly alter any effector functions. Regarding IPA, treatment with POS resulted in reduced fungal burden as expected but lead to reduced albumin concentration in BAL (111 ng/ml +/- 46 *vs* 380 +/- 31, *) indicating a decreased pulmonary damage. Despite significant influence on PMN effector functions *in vitro*, MIC did not affect clinical course IPA *in vivo*.
Summary/Conclusions: AmB and POS induce PMN activation, whereas ISA and MIC inhibit PMN effector functions *in vitro.* CAS shows variable modification on PMN. Possibly independent from its antifungal effects, POS reduces pulmonary damage in mice suffering from IPA *in vivo*. Further studies are needed to distinguish the obviously multidimensional immunomodulatory effects of different antifungal agents and to clarify their relevance in clinical practice.

P644

CHARACTERISTICS AND OUTCOME OF PULMONARY INFILTRATES IN ACUTE LEUKEMIA CLASSIFIED ACCORDING TO EORTC/MSG CRITERIA OF INVASIVE FUNGAL INFECTION: A PROSPECTIVE STUDY BY THE RETE EMATOLOGICA LOMBARDA

C. Cattaneo[1,*], C. Pagani[1], V. Mancini[2], P. Zappasodi[3], A. Ferrario[4], F. Pavesi[5], E. Todisco[6], N.S. Fracchiolla[7], V. Saccà[8], L. Verga[9], M. Petullà[1], A. Nosari[2], G. Rossi[1]
[1]Hematology, Spedali Civili, Brescia, [2]Hematology, Ospedale Niguarda, Milan, [3]Fondazione IRCCS Policlinico S. Matteo, Pavia, [4]Hematology, Ospedale di Circolo e Fondazione Macchi, Varese, [5]San Raffaele Scientific Institute of Milan, Milan, [6]Humanitas Cancer Center, Rozzano-Milano, [7]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, [8]Hematology, Ospedale Valduce, Como, [9]Hematology, San Gerardo Hospital, Monza, Italy

Background: In acute leukemia (AL) patients (pts) pulmonary infections may be severe and worsen the final outcome of AL. They have been recently shown to adversely affect the outcome of bloodstream infections (BSI) in AL pts (Cattaneo et al, 2016). The radiologic characteristics of PI belong, according to the EORTC/MSG Study Group, to the diagnostic criteria of a pulmonary invasive fungal infection (IFI).
Aims: In order to better define the clinical and prognostic significance of PI in AL pts in a real-life setting, we have analyzed all PI diagnosed during consecutive febrile/infectious episodes developing over a 26 months period in pts admitted to 9 hematological institutions within the Rete Ematologica Lombarda (REL) network.
Methods: From Dec-12 to Jan-14, all febrile/infectious episodes were recorded and data concerning PI extracted. PI were classified as *specific* and *aspecific* for IFI according to radiologic criteria.
Results: During 1086 episodes, 256 PI were diagnosed in 195 AL pts (M/F 124/71; median age 60y; AML/ALL 163/32). PI incidence was similar during induction and relapse (28.8% and 29%, respectively), but significantly lower in complete remission (14.2%, p<0.0001). Overall, PI were detected in 57% of cases during AML induction/reinduction and in 44.5% during posaconazole prophylaxis. Posaconazole was not responsible for a decreased sensitivity of serum galactomannan (GM), which was positive in 18.4% and in 18.6% pts with *specific* PI receiving posaconazole or not, respectively. *Aspecific* PI were observed in 157 cases (61.3%). In the remaining 99 cases (38.3%) the *specific* radiologic criteria for suspecting IFI were met, but in 70 of them (27.3%) just in the context of a diagnosis of possible (poss) IFI. Probable/proven (prob/prov) IFI criteria were met in 29 PI (11.3%). The characteristics of the three subgroups of PI are listed in Tab 1. Prob/prov IFI PI were associated with lack of posaconazole prophylaxis in comparison with poss IFI (72.4% *vs* 57.1%, p=0.0074). *Aspecific* PI did not differ from poss IFI except for their lower frequency during neutropenia, particularly if ≥15d (80.3% *vs* 92.9%, p=0.0164, and 56.1% *vs* 80%, p=0.0005, respectively), and higher frequency in patients on Fluoroquinolone (Fq) prophylaxis (57.3% *vs* 22.9%, p<0.0001). Multivariate analysis confirmed that *aspecific* PI were less frequent during prolonged neutropenia (HR 0.382, IC 0.189-0.772), and poss IFI during Fq prophylaxis (0.344, 0.159-0.742). All but two *specific* PI were treated with systemic antimold therapy. Thirty-day mortality was observed in 41 cases (16%). It was similar for *aspecific* and poss IFI (15.9% and 10%), but significantly higher in prob/prov IFI (31.3%, p=0.0192). Multivariate analysis confirmed a prob/prov IFI (3.277, 1.243-8.644) predictive for death, as well as relapsed/refractory AL (2.45,1.092-5.498) and BSI (2.383, 1.056-5.377).

Table 1.

	ASPECIFIC PI	POSS IFI	PROB/PROV IFI
	157 (%)	70 (%)	29 (%)
AML	85,3	84,3	79,3
Age>60	50,3	41,4	58,6
M sex	61,8	60	79,3
Induction	45,9	45,7	51,7
CR	24,8	15,7	20,7
Rel/Refr	29,3	38,5	27,6
PMN<500	80,3	92,9	89,7
Npenia≥15g	56,1	80	72,4
Fq Y	57,3	22,9	44,8
Posaconazole N	51,5	57,1	72,4
BSI Y	31,8	42,8	41,4
Death	15,9	10	31

Summary/Conclusions: Among PI occurring in AL patients IFI could be suspected according to EORTC/MSG Study Group criteria in nearly 40% of cases but only 11% of PI met the criteria for prob/prov IFI. Posaconazole did not affect serum GM sensitivity and was protective against prob/prov PI, which had a higher risk of death. On the other hand, PI associated with a diagnosis of poss IFI had a similar outcome compared to aspecific PI, although they occurred more frequently during neutropenia and outside from Fq prophylaxis. These findings may be relevant in the context of a reevaluation of the criteria for suspecting IFI in AL patients with PI as well as for a more appropriate antimicrobial stewardship.

P645

ANTIFUNGAL PROPHYLAXIS WITH CD101 IN IMMUNOSUPPRESSED MOUSE MODELS OF CANDIDIASIS, ASPERGILLOSIS, AND PNEUMOCYSTIS PNEUMONIA (PCP)

V. Ong[1,*], K. Bartizal[1], M. Cushion[2], L. Miesel[3], S.R. Lopez[4]
[1]Cidara Therapeutics, Inc., San Diego, [2]Cincinnati VAMC; Univ of Cincinnati Coll of Med, Cincinnati, United States, [3]Eurofins Panlabs, Taipei, Taiwan, Republic of China, [4]TransPharm Preclinical Solutions, Jackson, United States

Background: Fungal infections continue to carry high morbidity and mortality. Disease- and treatment-related immunosuppression in patients with hematological diseases increase the risk of opportunistic infection caused by *Candida* spp., *Aspergillus* spp., and *Pneumocystis* spp., and antifungal prophylaxis is an important consideration. Agents currently used for prophylaxis, voriconazole and TMP/SMX, carry safety and tolerability concerns. CD101 is a novel echinocandin in phase 2 clinical development that has demonstrated preclinical efficacy in treatment of invasive fungal infections and has physical and pharmacokinetic attributes that enable once-weekly IV dosing and subcutaneous (SC) administration.
Aims: To evaluate CD101 as antifungal prophylaxis in neutropenic mouse models of candidiasis, aspergillosis, or PCP.
Methods: Candidiasis model: ICR mice (5/grp) were rendered neutropenic by cyclophosphamide (cpm) on day -4 (150mg/kg) and day -1 (100mg/kg) and challenged (day 0) with *Candida albicans* ATCC SC5314 (IV, 100 µL, 10^5 CFU/mouse). One dose of CD101 5, 10, or 20mg/kg SC was given prior to challenge on day -5, -3, or -1. Kidneys were removed for CFU enumeration 24 h postchallenge. **Aspergillosis model**: ICR mice (6/grp) were rendered neutropenic by cpm on days -3 (6mg/mouse), +1 and +4 (2mg/mouse) and then challenged (day 0) with *Aspergillus fumigatus* ATCC 13073 (IV, 100µL, 10^4 CFU/mouse). One dose of CD101 5, 10, or 20mg/kg SC was given prior to

challenge on day -5, -3, or -1. Survival was monitored for 14 days. **PCP model**: C3H/HeN mice (10/grp) were immunosuppressed by dexamethasone (4mg/L) in acidified drinking water and inoculated with *Pneumocystis murina* (intranasally, 2 x 10^6/50 µL). CD101 0.2, 2, or 20mg/kg intraperitoneally was given at the time of inoculation and 1x or 3x/wk for 6 wks. TMP/SMX 50/250mg/kg/3x/wk was used as positive control. At 6 wks, lungs were processed for quantification of trophic and asci (cyst) forms of *P. murina*.
Results: Candidiasis: Kidney CFU decreased with higher doses of CD101 and shorter times between prophylaxis and challenge. At 20mg/kg, there was complete clearance of CFU burden regardless of treatment day in all animals except one (prophylaxis on day -3). There was complete clearance in all animals given 10mg/kg on days -3 and -1 and significant decreases in CFU in those given 5mg/kg on days -3 and -1. **Aspergillosis**: Survival rates significantly increased following CD101 5, 10, and 20mg/kg prophylaxis on day -5, -3 or -1 compared with vehicle. Prophylaxis closer to challenge increased the rate of survival in the 5mg/kg group. All animals given higher doses survived regardless of day of prophylaxis. **PCP**: Trophic nuclei counts were significantly reduced *versus* untreated controls in all CD101 groups except 0.2mg/kg/1x/wk, and efficacy in 3 different CD101 groups was comparable to TMP/SMX (no nuclei observed microscopically). Asci counts also were significantly reduced in all CD101 groups *versus* untreated controls. There was no difference in efficacy between TMP/SMX and CD101 in all but the lowest dose group (0.2mg/kg/1x/wk), with no asci observed microscopically.
Summary/Conclusions: CD101, a novel echinocandin, was protective against fungal challenge in immunosuppressed mouse models of candidiasis, aspergillosis, and PCP. These data suggest that CD101 may provide benefit as antifungal prophylaxis in patients with hematological diseases at risk for infection. The efficacy of SC-administered CD101 demonstrated in the candidiasis and aspergillosis models suggests potential utility in the outpatient setting for treatment or prophylaxis.

P646

SURGICAL MANAGEMENT OF INVASIVE FUNGAL INFECTIONS IN ADULT LEUKAEMIA PATIENTS–EXPERIENCE FROM A LARGE TERTIARY CENTRE IN SOUTH-EAST ASIA

C. Nagarajan[1,*], Y.C. Tan[1], T.T. Tan[2], W. Hwang[1], Y.C. Linn[1], A. Ho Yew Leng[1], A.L. Ang[1], R. Yiu Cheung[1], N.F. Grigoropoulos[1], B.H. Tan[2], G.C. Wong[1]
[1]Department of Haematology, [2]Department of Infectious Diseases, Singapore General Hospital, Singapore, Singapore

Background: Invasive fungal infections (IFI) are a major cause of morbidity and mortality in patients undergoing chemotherapy or stem cell transplantation for acute leukaemias. Though optimised antifungal therapy might be effective, in selected patients, surgical interventions might be an useful tool both for diagnostic and therapeutic reasons. However due to the nature of the disease and circumstances, prospective data of Surgical interventions in these situations is very difficult and the evidence is usually from small cohorts often from single centers.
Aims: The purpose of this study is to report our single center experience of surgical interventions for IFI in acute leukaemia patients.

Table 1.

Number of surgical procedures	20 (in 19 patients)
Organs involved	11 isolated pulmonary/pleural, 3 disseminated, 2 Sino-nasal, 2 cardio-pulmonary and 1multiple organ (lung and spleen) involvement
Types of Surgery	2 – Thoracotomy with decortication 5 – VATS (4 upper lobe and 1 lower lobe wedge resection) 6 – Open thoracotomies - 1 middle and upper lobe and 2 upper lobe wedge resections, 1 each upper and lower lobectomies, 1 pericardial window 4 – Endoscopic sinus surgeries(FESS) 1 – Splenectomy 1 – Abscess drainage and debridement 1 – Multiple procedures (arthrotomy for pus drainage and radial reaming) – also had FESS
Proven IFI	Aspergillus –5, Fusarium –2, Mucor –1, Unknown Molds –5 Candida – 1, Dual – Mold in Lung and Candida in blood – 1
Confirmation of Diagnosis	Histology alone – 7 Histology and culture – 5 Culture alone – 2 1 – Aspergillus PCR
Complications	Pleural effusions – 2 Pneumothorax – 4 (1patient with extensive subcutaneous emphysema) Hydropneumothorax - 1
Antifungal Treatment	Monotherapy – 10 (1 Caspofungin,6 Liposomal amphotericin, 3 Azoles) Combination therapy – 4 (2 Liposomal amphotericin + azoles, 1 Caspofungin + Voriconazole, 1 Anidulafungin + Voriconazole) Tandem therapies – 3 (Caspofungin → Liposomal amphotericin, Caspofungin → Voriconazole, Liposomal amphotericin → Voriconazole) Info not available – 2 patients

Methods: A retrospective review of our Hospital's Leukaemia database (IRB approved) was made for clinical characteristics and outcomes in surgically managed IFI patients diagnosed between Jan 2005 and Dec 2015. IFI was defined by EORTC/MSG 2008 criteria.
Results: Among 795 acute leukaemia patients diagnosed during this period, we found 19 patients with IFI who had undergone surgical interventions (15 proven, 1 probable and 3 possible IFI). The details of the IFI, surgical interventions, antifungal treatments and perioperative complications are summarized in Table 1. Most commonly performed surgical intervention was either open thoracotomy or video assisted thoracoscopic surgery for wedge resection or lobectomy. Nine of the 15 proven IFI patients had overall benefit from the procedure through optimization of antifungal therapy with MIC/sensitivities, arrest of aspergilloma related massive bleeding and/or complete resolution of the IFI allowing further chemotherapy or transplantation. Of these, 7 patients were alive and well at the time of data collection and 2 had died. Among the survivors, the mean duration of the survival post-surgery was 57.7months (range 9–118.3 months). The 2 patients who died also had benefitted from the procedure and had survived for 6.5 and 47 months post-surgery but both succumbed to septic events unrelated to the IFI during subsequent chemotherapy. Of the remaining 6 patients (out of the 15 proven IFI), 3 had temporary clinical and/or radiological improvement only but succumbed 2 to 6 months post-surgery due to unrelated septic events, 2 died due to progression of the IFI despite treatment and 1 lacked information to draw any conclusions. The patient with probable IFI diagnosed during induction was able to proceed with further chemotherapy post-surgery but succumbed to CNS relapse of leukaemia 8 months later. Of the 3 patients with possible IFI, 2 were able to proceed with transplantation and 1 with chemotherapy post-surgery, but all the 3 patients succumbed to leukaemia and/or unrelated septic events.
Summary/Conclusions: Major surgical interventions are feasible in selected leukaemia patients with IFI. In carefully selected patients they can yield valuable information to guide anti-fungal therapy or enable therapeutic outcomes allowing patients to proceed with curative chemotherapy and stem cell transplantation.

Background: The outcome of patients with multiple myeloma (MM) has improved dramatically in the past years, mainly due to a better control of the disease. However, it is not clear what influence this has on treatment- or disease-related complications like infections. Recent data even suggested an increased rate of infections in patients with MM, possibly associated with the use of novel drugs.
Aims: To determine the rate and the type of infections in MM patients undergoing treatment and to evaluate possible disease- or treatment-related risk-factors.
Methods: All patients with MM treated at our institution between 2003 and 2014 were included in this retrospective analysis after approval by the institutional review board. Data on age, sex, diagnosis, comorbidities, treatment modalities, and infectious complications were recorded. Each type of therapy (*e.g.* high-dose therapy *versus* conventional therapy) defined a patient-case (duration per patient-case: beginning of therapy until the beginning of another type of therapy) and infections were recorded per case. To determine risk-factors, generalized estimating equations comparing cases were used.
Results: Four-hundred seventy-nine patients (male: 272, 57%) accounted for 1690 cases (median number of cases per patient 3, range 1-15). At presentation in our institution, median age was 62 (35-89) years, and most patients had advanced disease (Stage III according to Salmon-Durie classification in 364 patients, 76%) and an IgG-paraprotein (255 patients, 53%). Type of therapy given were as follows: 534 (32%) conventional long-term chemotherapy, 514 (30%) induction-type chemotherapy, 237 (14%) chemotherapy for stem-cell mobilisation, 310 (18%) high-dose melphalan with stem-cell transplantation and 95 (6%) supportive care only. One-hundred sixty-six patients (35%) with 295 patient cases never experienced an infection including 25 cases with high-dose melphalan. However, the majority of patients experienced at least one episode of infection throughout their treatment, accounting for 773 infections in 627 patient cases (37% of all patient cases). Most (559, 72%) infections were of bacterial origin including 156 cases with pneumonia (9% of all patient cases). Herpes zoster was noted in 37 patient cases. Relapse (OR 1.9, 95% CI 1.5-2.5, $p<0.001$) and high-dose chemotherapy (OR 11.3, 95% CI 8.4-15.3, $p<0.001$) were associated with a higher risk of infection whereas time of treatment (2003-2008 *versus* 2009-2014) or use of novel drugs did not influence the rate of infection.
Summary/Conclusions: More than 60% of MM patients experience at least one episode of infection during their course of treatment. These infections are mostly of bacterial origin and strongly associated with high-dose chemotherapy or relapse. Novel drugs do not seem to influence the rate of infection. Unfortu-

nately, despite the general improvement in the care of patients with MM, no difference in the rate of infections could be detected in recent years.

P648

HUMAN L-FICOLIN POLYMORPHISMS CONTRIBUTE TO SUSCEPTIBILITY TO INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

U. Schnetzke[1,*], M. Fischer[1], A. Hochhaus[1], S. Scholl[1]
[1]Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: In neutropenic patients with acute myeloid leukemia (AML) bacterial infections and sepsis are a leading cause of mortality. Several studies propose a contribution of individual single nucleotide polymorphisms (SNPs) of the innate immune system to the course of infections. Human ficolins represent recognition molecules of the lectin complement pathway whereas especially ficolin-2 (L-ficolin) is emerging as an important component of the lectin pathway in the circulation. Ficolins share structural and functional characteristics with C1q from the classical pathway of the complement that acts with Pentraxin 3 (PTX3) that helps the innate immune system targeting pathogens like bacteria or viruses. In the context of hematopoietic stem cell transplantation polymorphisms of PTX3 have been identified as an individual risk factor for developing pulmonary aspergillosis.
Aims: We sought to investigate the impact of L-ficolin and PTX3 SNPs on the occurrence of infectious events such as sepsis and pneumonia, including invasive fungal disease (IFD), in 186 adult patients with newly diagnosed AML following anthracycline-based induction chemotherapy. In addition to our studies on membrane receptors**,** this work represents an important extension on soluble molecules of the innate immune system and their potential implication on infections.
Methods: Genotyping of L-ficolin and PTX3 SNPs (rs17514136, rs17549193, rs1800450 and rs3816527, rs2305619, rs1840680) was performed by TaqMan assay. Multiple logistic regression analyses were applied to evaluate the association between the polymorphisms and the occurrence of infectious events.
Results: Two L-ficolins SNPs were identified as risk factors for developing sepsis and/or pneumonia. Patients harboring $rs17514136_{GG/AG\ or\ GG}$ (n=100 or 22) revealed a significantly higher risk for developing sepsis (odds ratio (OR): 1.88; 95% confidence interval (CI): 1.01–3.37, p=0.039) or pneumonia (OR: 2.79; 95% CI: 1.1–6.9, p=0.033). A similar risk profile could be demonstrated for patients carrying $rs17549193_{TT/CT\ or\ TT}$. No association was found between SNPs of the PTX3 gene and the analysed infectious events.
Summary/Conclusions: To our best knowledge, this study represents the first analysis demonstrating that polymorphisms of human L-ficolin (rs7309123, rs17549193) represent an independent risk factor of developing sepsis and/or pneumonia in patients with AML undergoing induction chemotherapy. Interestingly, no association of PTX3 SNPs and infectious events such as IFD was found in this non-transplant setting. In conlusion, a genetic risk profile based on membrane bound and soluble molecules of the innate immune system might be helpful in identifying patients prone for infectious events.

PREDICTIVE FACTORS OF RESPONSE TO EPOETIN THETA IN CHEMOTHERAPY-INDUCED ANEMIA: A FRENCH MULTICENTER OBSERVATIONAL STUDY (PIVOINE)

P. Rodon[1,*], B. Bareau[2], K. Benabed[3], V. Boulanger[4], J. Dauba[5], M. El Demery6, J.-L. Labourey[7], F. Maloisel[8], A. Mercier Blas[9], T. Nakry[10], M. Rotarski[11], H.H. Saadoun[12], F. Monchecourt[13]
[1]Hôpital De Jour, Ch De Perigueux, Perigueux, [2]Hopital Prive Cesson Sevigne, Cesson Sevigne, [3]Hématologie Clinique, Hopital Cote De Nacre, Caen, [4]Ch De Carcassonne, Carcassonne, [5]Médecine Ambulatoire, Hopital Layne, Mont De Marsan, [6]Hôpital De Jour Chimiothérapie, Clinique Du Cap D'or, La Seyne Sur Mer, [7]Oncologie, Ch Antoine Gayraud, Carcassonne, [8]Centre De Radiotherapie, Strasbourg, [9]Centre De Radiotherapie St Vincent, St Gregoire, [10]Hématologie - Oncologie, Ch De Beziers, Beziers, [11]Centre Oncologie Du Pays Basque, Bayonne, [12]Hospitalisation Oncologie, Hopital Saint Jean, Perpignan, [13]Affaires Médicales, Teva Santé, La Défense, France

Background: Whereas erythropoiesis stimulating agents (ESA) are indicated in the management of chemotherapy-induced anemia (CIA), their use in clinical practice is a matter of controversy with regards to some meta-analyses, opinions released by regulatory institutions and available international guidelines. However, supportive care is an area of high importance in onco-hematology thus justifying to study the use of ESA in cancer patients in the real-life setting.
Aims: The PIVOINE study aims to provide a better knowledge about the use of epoetin theta for the treatment of CIA in onco-hematology in the real-life setting and to identify predictive factors of response to ESA.
Methods: Multicenter, observational, prospective study conducted with 136 oncologists or onco-hematologists on adult patients suffering from non-myeloid malignant tumors, treated with chemotherapy and initiating epoetin theta treatment according to standard medical practice.
Results: From November 2014 to October 2015, 1379 evaluable patients were followed in the study (mean age 68.3 ± 11.3 years, 47.2% men). Overall, 21.8% of patients presented with hematological malignancies, 19.9% with digestive tumors, 18.2% with lung cancer and 40.1% with other solid tumors. The majority had a good performance status (75.2% ECOG 0-1). More than 90% of patients had never received ESA prior to enrolment in this study and 45.2% benefited from first-line chemotherapy. Median Hb level at inclusion was 9.7 g/dL. Epoetin theta was initiated at a weekly dose of 20 000 IU for 76.1% of patients and 12.3% of patients benefited from dose adaptation during follow-up, mainly dose increase (90.5%). Overall, 18.5% of patients received blood transfusion during the study. Five-hundred and sixty-three patients (45.2%) achieved complete response (CR) (i.e. Hb level increased by at least 2 g/dL) within 12 weeks after epoetin theta initiation. According to Kaplan-Meier analysis, the probability of CR was 12.7% at 4 weeks, 35.8% at 8 weeks and 52.4% at 12 weeks. Multivariate analysis showed that the lower the Hb level at baseline, the greater the chance of complete response (OR 0.4 IC95% [0.335;0.478]). Moreover, good performance status (ECOG 0 or 1), hematological malignancies (vs. solid tumor) and the absence of blood transfusion are independent predictive factors for complete response (OR 1.577 IC95% [1.186;2.098], OR 1.946 IC95% [1.459;2.597], OR 1. 969 IC95% [1.411;2.747] respectively). Overall, only 27 patients (2%) experienced treatment-related adverse events, 2 of them (0.1%) presenting with a serious one (non fatal pulmonary embolism).
Summary/Conclusions: The PIVOINE study confirms that the response rate to epoetin theta varies considerably among patients treated similarly. This observational study conducted on a large population could help targeting the patients that could positively benefit from such treatment to prevent CIA, mainly patients with hematological malignancy, with good performance status and with low initial Hb level. The safety results confirmed the safety profile of epoetin theta.

P650

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER PRIMARY CHEMOTHERAPY: EXPLORATORY ANALYSIS OF AN EXPANDED-ACCESS PROTOCOL

N. Kernan[1], P. Richardson[2,*], B. Triplett[3], S. Grupp[4], J. Antin[5], W. Liang[6], R. Hume[6], W. Tappe[6], R. Soiffer[7]
[1]Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, [2]Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [3]Bone Marrow Transplantation and Cellular Therapy, St. Jude Children's Research Hospital, Memphis, [4]Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, [5]Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, [6]Jazz Pharmaceuticals, Inc., Palo Alto, [7]Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT); however, VOD/SOS can occur after chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States.
Aims: To perform an exploratory *post hoc* analysis of the impact of timing of initiation of defibrotide after VOD/SOS diagnosis in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).
Methods: In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25mg/kg/d (4 divided doses of 6.25mg/kg) was given a recommended ≥21 days after patients provided informed consent. In this post-chemotherapy subgroup, survival was analyzed *post hoc* from the day VOD/SOS was diagnosed (days 0–30 after start of chemotherapy) through follow-up, which was collected for 100 days post-chemotherapy. For these exploratory analyses, survival rates in the post-chemotherapy subgroup were examined by time from VOD/SOS diagnosis to start of defibrotide for (1) all patients before/after days 1, 2, 3, 4, 7, and 14, using Fisher's exact test and (2) patients starting defibrotide on a particular day: 0, 1, 2, 3, 4, 5, 6, 7, 8–14, and ≥15, by Cochran-Armitage test for trend across days. Causes of treatment delay were not assessed.
Results: In the final dataset, 137 patients developed VOD/SOS after primary chemotherapy. Of these, 87 patients (41 with MOD) developed VOD/SOS by day 30 after the start of chemotherapy. In the latter group, 79.3% (69/87) were aged ≤16 years. In 26.4% (23/87) of post-chemotherapy patients, defibrotide was started the day of diagnosis; in 89.7% (78/87), by Day 7. In the population-wide analysis of initiation before/after days 1, 2, 3, 4, 7, and 14 post-diagnosis in both the overall group and MOD subgroup (**Figure**), earlier initiation was associated with higher Day +100 survival rates for all days, which was significant at a number of timepoints. The trend test for particular initiation days

also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall group and MOD subgroup (P<.05). In the overall post-chemotherapy population, adverse events (AEs) and serious AEs occurred in 66% and 40% of patients, respectively. Aside from multi-organ failure, the most common AE of any severity was hypotension (9.5%). Possibly related AEs lead to discontinuation in 7.3%; most common was gastric hemorrhage (3.7%).

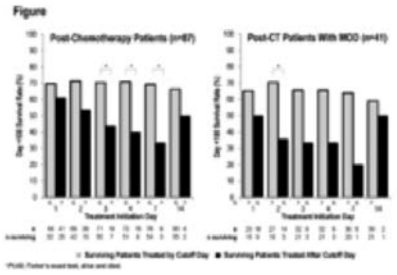

Figure 1.

Summary/Conclusions: In this exploratory analysis of final study data in the subgroup of patients developing VOD/SOS after chemotherapy, earlier defibrotide initiation post-VOD/SOS diagnosis was associated with improved Day +100 survival, confirmed by the Cochran-Armitage test (P<.05), even in the small MOD subgroup. This time-dependent relationship was consistent with that found in the HSCT subgroup from this study. No specific day appears to provide a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

ADAMTS-13 REGULATES NEUTROPHIL RECRUITMENT IN A MOUSE MODEL OF INVASIVE PULMONARY ASPERGILLOSIS

A. Hasibeder[1,*], S. Prüfer[2], K. Ebner[3], S. Reuter[1], P. Aranda Lopez[1], I. Scharrer[1], F. Banno[4], M. Stassen[2], H. Schild[2], K. Jurk[3], M. Bosmann[3], H. Beckert[1], M. Radsak[1]

[1]IIIrd Dept. of Medicine, [2]Institute for Immunology, [3]Center for Thrombosis and Hemostasis, Johannes Gutenberg-Universitiy Medical Center, Mainz, Germany, [4]Department of Molecular Pathogenesis, National Cerebral and Cardiovascular Center, Suita, Japan

Background: Von Willebrand factor (VWF) is produced as multimers of various sizes and is secreted as an acute phase protein during inflammation. The main mechanism regulating the size and prothrombotic activity of VWF is the specific proteolytic activity of ADAMTS-13 (a disintegrin and metalloprotease with ThromboSpondin type 1 repeats-13) which is diminished under several pathological conditions.
Aims: To determine the relevance of this regulatory pathway for the innate inflammatory response by polymorphonuclear neutrophils (PMN), we employed a mouse model of invasive pulmonary aspergillosis (IPA) where PMN functionality is crucial for fungal clearance and survival.
Methods: IPA was induced by intratracheal application of *Aspergillus fumigatus* (*A. f.*) conidia in wildtype (129/Sv/Pas) or ADAMTS-13 deficient (*Adamts13*$^{-/-}$) mice, and VWF deficient (*Vwf*$^{-/-}$) mice or respective controls (B6). Some mice were sacrificed 24 h after infection. Fungal load was assessed as colony forming units (CFU) after plating and culturing lung homogenates on Sabouraud agar plates. For histological analysis paraffin sections of the lungs were stained with H&E, mouse complement component C3d and VWF antibody. Broncho alveolar lavage fluid (BALF) was analyzed for cell count (bead-based by flow cytometry or by an animal blood counter), ELISA was performed for albumin amount and cytokines were analyzed by a multiplex assay. Bone marrow-derived PMN were isolated by magnetic cell sorting using biotin labeled Ly6G/C specific antibody. PMN functions were analyzed for degranulation, oxidative burst activity and CD62L shedding by flow cytometry. Fungal killing of PMN *in vitro* was assessed by a XTT assay. Chemotactic properties of *A.f.*-activated and control serum from wildtype and knock-out mice was evaluated by migration of purified human PMN, isolated by dextran sedimentation and Histopaque® centrifugation, in a transwell assay.
Results: While infected neutropenic mice developed lethal IPA, all wildtype mice survived the infection. Interestingly, *Adamts13*$^{-/-}$ mice displayed more severe signs of disease with a lethal course in about 24% of the animals. Examination of the lungs revealed a higher fungal burden along with increased signs of acute lung injury and levels of pro-inflammatory cytokines in ADAMTS-13 deficiency. Histology sections demonstrated a more pronounced perivascular leukocyte infiltration in support of a dysregulated inflammatory response in *Adamts13*$^{-/-}$ mice. Importantly, we observed no general defect in the activation of neutrophil effector functions in response to conidia or hyphae *in vitro*. Furthermore, innate inflammatory response to IPA was not altered in VWF deficient (*Vwf*$^{-/-}$) mice compared to wildtype (B6) control.
Summary/Conclusions: Therefore, we conclude that the proteolytic regulation of VWF by ADAMTS-13 or ADAMTS-13 by itself is an important mechanism to control PMN recruitment in acute inflammatory processes, such as fungal pneumonias.

Myelodysplastic syndromes - Biology

P652

IDENTIFICATION OF THE SPECIFIC HEMATOPOIETIC STEM CELL POPULATIONS RESPONSIBLE FOR FAILURE TO HYPOMETHYLATING AGENTS IN MYELODYSPLASTIC SYNDROMES

I. Gañán-Gómez[1,*], A. Alfonso[1], Y. Ogoti[1], H. Yang[1], G. Montalban-Bravo[1], A.C. Yu[2], S. Silver[2], K. Clise-Dwyer[3], G. Garcia-Manero[1], S. Colla[1]
[1]Leukemia, The University of Texas MD Anderson Cancer Center, [2]McGovern Medical School, The University of Texas Health Science Center, [3]Stem Cell Transplantation & Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Myelodysplastic syndromes (MDS) are hematopoietic disorders characterized by the ineffective production of mature blood cells of one or more lineages and by the risk of evolution to acute myeloid leukemia. The current standard of care for MDS patients is the treatment with hypomethylating agents (HMA); however, response to drugs from this family occurs in just about half of the patients and is accompanied by high rates of therapy failure. Failure to HMA in MDS is a poorly understood process associated to increased risk of disease progression and to a dismal prognosis and cannot be, thus far, predicted or prevented.
Aims: Given that MDS are stem cell disorders, our aim was the identification and molecular characterization of the specific hematopoietic stem/progenitor cell (HSPC) population in which the relapse-driver clones arise. This is an essential step for the development of effective monitoring and early intervention protocols for HMA failure.

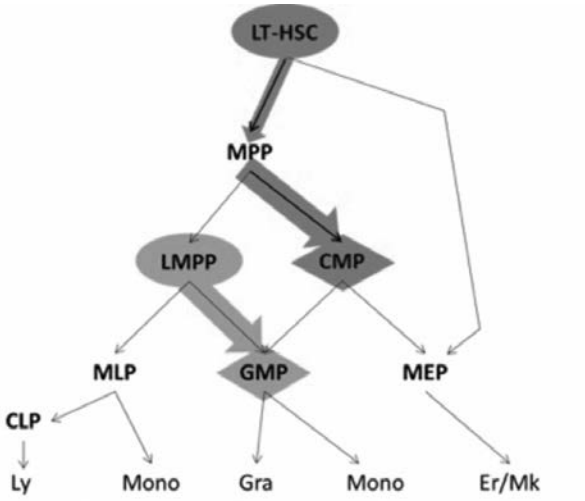

Figure 1. Working model of hematopoietic abnormalities in MDS. Colored arrows indicate differentiation steps that seem to be favored at the expense of others in each MDS subtype. Red represents CMP pattern MDS; blue represents GMP pattern MDS. Diamonds indicate the myeloid progenitor population that is predominant in each subtype. Ellipses indicate the populations that expand during HMA failure with blast progression.

Figure 1.

Methods: Using flow cytometry immunophenotyping, we quantitatively analyzed the different cell subpopulations within the $CD34^+CD38^-$ and $CD34^+CD38^+$ HSPC compartments in 122 sequential MDS bone marrow samples obtained from 93 patients at different stages of HMA treatment.
Results: In line with earlier reports suggesting the presence of alterations in myeloid progenitor frequencies in MDS, our flow cytometry data stratified untreated patient samples in two groups representative of two abnormal differentiation patterns, which were independent of the IPSS risk classification. The "CMP pattern" group (12 samples, 34%) was characterized by an increased frequency of the common myeloid progenitors (CMP) (2.6-fold; $p<10^{-4}$), whereas the "GMP pattern" group (23 samples, 66%) was characterized by the increased frequency of the granulo-monocytic progenitors (GMP) (1.7-fold; $p<10^{-3}$) within the HPC compartment, when compared to those from healthy individuals. Importantly, these two patterns were not caused by the expansion of the aforementioned populations, but by the depletion of other progenitors within the same compartment, which points to the existence of selective differentiation defects in upstream HSC or multipotent progenitors (MPP). For instance, decreased numbers of long-term (LT)-HSC (-5.1-fold, p=0.001) and increased counts of the GMP precursors, lymphoid-primed multipotent progenitors (LMPP) (4.7-fold, p=0.016), were observed in GMP pattern patients but not in CMP pattern patients. These data suggest that each abnormal differentiation pattern arises from defects in different HSC populations and has a differential impact in the number and functionality of downstream progenitor cells (Figure 1). In agreement, a deeper immunophenotypic analysis of recently defined HPC functional fractions showed decreased erythroid and megakaryocytic potential in CMP (-2-fold each, $p<0.05$) and megakaryocytic-erythroid progenitor (MEP) populations (-3.8-fold erythroid, -7.6-fold megakaryocytic; p=0.07, p=0.04, respectively) from CMP pattern patients but not in GMP pattern patients. HSPC frequency-monitoring of 69 samples collected from 36 patients throughout therapy showed persistence of both abnormal differentiation patterns even during clinical remission. Furthermore, specific HSC populations were differentially expanded upon HMA failure with leukemic progression in the two groups of patients. In CMP pattern MDS, LT-HSC frequency significantly increased after relapse (10.4-fold; $p<10^{-4}$), whereas the LMPP frequency sharply increased (8-fold; $p<10^{-4}$) in GMP pattern patients. The fact that a proliferative switch occurred in different HSC subpopulations confirmed that the two subgroups are distinct entities with different hierarchical origins.
Summary/Conclusions: Overall, our data provide evidence of the existence of biologically different MDS subtypes which are caused by separate differentiation defects and progress through the expansion of characteristic HSC populations.

P653

FUNCTIONAL STUDY ON THE COOPERATION OF ASXL1 AND RUNX1 MUTATIONS FOR LEUKEMIC TRANSFORMATION

R. Bera[1,*], D.-C. Liang[2], M.-C. Chiu[1], Y.-J. Huang[1], L.-Y. Shih[3]
[1]Chang Gung Memorial Hospital, Taoyuan, [2]Mackay Memorial Hospital, Taipei, [3]Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan, Republic of China

Background: Our previous studies showed that *RUNX1* and *ASXL1* mutations were frequently co-existed in chronic myelomonocytic leukemia (CMML) (EHA 2015) and clonal evolution of *RUNX1* and/or *ASXL1* occurred most frequently in chronic myeloid leukemia (CML) with myeloid blastic crisis (EHA 2016). The molecular pathogenesis of cooperation of *RUNX1* and *ASXL1* mutations has not been reported yet.
Aims: We aimed to determine the functional role of collaborative association of *RUNX1* and *ASXL1* mutations for secondary acute myeloid leukemia (sAML) transformation.
Methods: For *in vitro* study, we overexpressed *RUNX1*-WT/MT (R135T) in K562 cells which harboring *ASXL1*-MT (Y591X) and co-expressed with *ASXL1*-WT/MT (R693X) in murine 32D cells. After stable expression, functional properties were examined by using immunoblot, co-immunoprecipitation, quantitative RT-PCR, flow cytometry, cell proliferation, colony formation and gene expression microarray analyses. C57BL/6 mice were used for bone marrow transplantation (BMT) experiments for *in vivo* study.
Results: We found that *RUNX1*-MT augmented cell proliferation, colony formation, *HOXA* gene expression and inhibited megakaryocytic differentiation in *ASXL1*-MT K562 cells compared to *RUNX1*-WT or empty vector control. The cooperation of *RUNX1* and *ASXL1* mutations or the knocked down of *ASXL1* cooperating with *RUNX1*-MT inhibited apoptosis and impaired differentiation in 32D cells. Nine months post BMT mice with the combined *RUNX1* and *ASXL1* mutations, but not *RUNX1*-MT or *ASXL1*-MT alone, developed disease characterized by marked splenomegaly, hepatomegaly, and leukocytosis with a shorter latency. We found that RUNX1-MT stabilized hypoxia-inducible factor 1α (HIF1-α) and increased its target gene expression such as *ID1* (inhibitor of DNA binding 1). Clinical samples analyses showed that *ID1* expression increased in both *RUNX1*-MT and *ASXL1*-MT or the combined mutations of *RUNX1* and *ASXL1* compared to control samples. We also examined the impact of *RUNX1* and *ASXL1* mutations on sAML-free survival of 104 Patients with CMML in whom 11 had co-occurrence of *RUNX1* and *ASXL*1, 39 had either mutated *ASXL1* or *RUNX1* and 54 patients were negative for both mutations. We found that patients carrying co-existed mutations had a shorter sAML-free-survival (median 16.1 months, 95% CI 0.0-60.1 months) than those carrying either mutated gene alone (median 23.0 months, 95% CI 17.8-28.2 months) or negative for both mutated genes (median not reached, 59.2% ± 8.8%% at 5 years) (*P*=0.023).
Summary/Conclusions: The present study demonstrated that clinical and functional evidence for a collaborative association of RUNX1-MT and ASXL1-MT for sAML transformation. We identified HIF-1α targeting a new pathway which may be critical for leukemic progression of *RUNX1*/*ASXL1*-mutated myeloid malignancies.

P654

A NOVEL MASS SPECTROMETRY METHOD REVEALS THE INTRACELLULAR PHARMACOKINETICS OF AZACYTIDINE THERAPY IN VIVO

A. Unnikrishnan[1,*], A.V. Ngoc Quynh[1], R. Pickford[2], A. Nunez[1], L. Hesson[1], J. Pimanda[13]
[1]Prince of Wales Clinical School & Lowy Cancer Research Centre, [2]Bioanalytical Mass Spectrometry Facility, UNSW Sydney, [3]Haematology Department, Prince of Wales Hospital, Sydney, Australia

Background: The cytidine analog 5'-Azacitidine (AZA, Fig. A), a DNA demethylating agent, is the primary drug for the treatment of high-risk Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMML), and response is associated with improved survival benefits. However, only ~50% of treated patients will ever respond to AZA and the molecular basis for poor response is poorly understood. It is unclear whether non-responders to therapy have different rates of AZA uptake into their cells and/or AZA incorporation into nucleic acids compared to AZA responders, nor whether these might relate to DNA methylation *in vivo*.
Aims: We aimed to develop an analytical method capable of simultaneously detecting all the subcellular fractions of AZA (Fig B) within the bone marrows of patients undergoing AZA therapy, while also assessing DNA and RNA methylation levels. This would provide the most comprehensive snapshot of the intracellular pharmacokinetics of AZA therapy *in vivo* as a first step towards better understanding AZA resistance.
Methods: We have developed a new method utilising mass spectrometry to accurately quantify all the different subcellular fractions of AZA within the same sample (Fig C). Using an Orbitrap mass spectrometer with very high mass resolution, we have achieved the first mass separation of DAC and AZA from all naturally occurring isotopes of deoxycytidine and cytidine respectively (a difference of less than 1 Da), thus enabling accurate quantification. We utilised subcellular fractionation to obtain purified quantities of DNA- and RNA-incorporated nucleotides, as well as free unincorporated nucleotides present in the cytoplasm. We developed a reduction reaction to reduce the spontaneous hydrolysis of AZA and DAC, thereby greatly improving the sensitivity of detection.
Results: Using our new method, we report for the first time direct simultaneous quantification of: (1.) DNA-incorporated DAC, (2.) intracellular, free DAC, (3.) methyl deoxycytidine in DNA, (4.) RNA-incorporated AZA, (5.) intracellular, free AZA, and (6.) methyl cytidine in RNA within the same sample. We demonstrate an inverse correlation between the amount of DAC incorporated into DNA and DNA methylation. However, no such correlation was observed between AZA incorporation and RNA demethylation (Fig D). The sensitivity and resolution of our method also enabled, for the first time, a comprehensive survey of the total intracellular pharmacokinetics of AZA *in vivo* in patients undergoing a standard cycle of treatment. We discovered that the bone marrow cells of AZA responders (n=4) incorporated more DAC into DNA compared to non-responders (n=4). DAC incorporation was also inversely proportional to DNA methylation levels, with greater DNA demethylation observed in the responders compared to non-responders. Furthermore, we observed two patterns in AZA non-responders, with DAC-incorporation and DNA demethylation occurring in some individuals (n=2), while other non-responders (n=2) showed low or no DAC incorporation and no DNA demethylation (Fig E). Our method also enabled us to directly prove that low DAC incorporation was not a result insufficient AZA accumulation intracellularly, as cytoplasmic measurements of unincorporated AZA and DAC were highest in the non-responders with the lowest levels of DNA-incorporated DAC. Additionally, in these non-responders, there was also concomitant increase in AZA incorporation into RNA.

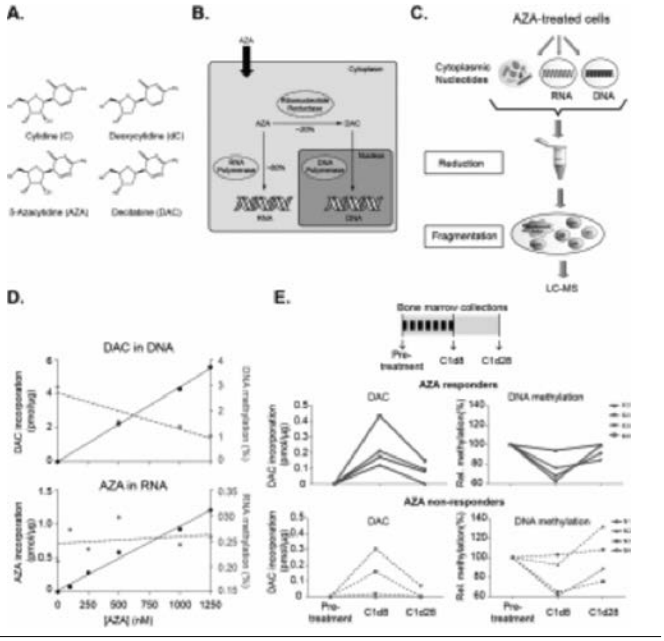

Figure 1.

Summary/Conclusions: We have developed a new method that has enabled the first comprehensive analysis of the intracellular pharmacokinetics of AZA therapy *in vivo*. Our results have revealed that while AZA responders incorporated AZA efficiently into DNA, leading to DNA demethylation, there were two modes of primary AZA resistance: in some non-responders, low levels of AZA incorporation into DNA likely derives from cell cycle quiescence, resulting in low amounts of DNA demethylation. However, in other non-responders who showed DAC incorporation into DNA and demethyltion, resistance arises from as-yet-unknown mechanisms not connected with AZA metabolism.

P655

CLONAL EVOLUTION OF STAG2 AND NRAS DURING PROGRESSION FROM MDS TO SAML ASSESSED BY WHOLE-EXOME AND TARGETED-DEEP SEQUENCING

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematological disorders at high risk of progression to acute myeloid leukemia (sAML). Due to recent high-throughput sequencing studies, the mutational dynamics and clonal evolution underlying disease progression have just begun to be understood. However, large longitudinal sequencing genomic studies are still required.
Aims: To analyze the relationship between the dynamics of gene mutations and cell pathways they are involved in with the progression from MDS to sAML in order to study the mechanisms underlying disease evolution.
Methods: Sixty-eight serially collected samples from 34 MDS/CMML patients evolving to sAML were studied by a combination of whole-exome sequencing (WES) and targeted-deep sequencing (TDS). Each patient was studied at two different time-points: at the time of diagnosis (MDS/CMML stage) and after sAML progression (disease evolution, leukemic phase). At initial presentation of the disease, diagnoses were as follows: 18 RAEB-1/2, 9 RCMD and 7 CMML. Initially, WES was carried out on 40 diagnosis/progression-matched samples. Driver mutations were identified, after variant calling by a standardized bioinformatics pipeline, by using the novel tool "Cancer Genome Interpreter" (https://www.cancergenomeinterpreter.org). Secondly, in order to validate mutations and precise variant allele frequencies (VAFs) estimation, TDS using a custom MDS/AML-related capture enrichment panel (Illumina ®) of 117 genes was performed in 30 out of 40 of the initial cohort. Moreover, a total of 28 paired-samples from a cohort of 14 patients were analyzed by TDS.
Results: Combining both WES and TDS approaches, a total of 143 mutations in 50 different genes were identified at the sAML stage, with most of them (118 mutations) already present at the MDS stage, at clonal or subclonal levels.
The most recurrently mutated genes were *SRSF2* (41%), *TET2* (41%), *STAG2* (28%), *SF3B1* (21%), *ASXL1* (21%), *TP53* (21%) and *NRAS* (21%). However, it should be noted that 68% genes were mutated only in less than 10% of the patients, highlighting the great heterogeneity that exists in the mechanisms of disease evolution. To study the mutational dynamics during disease progression we compared VAFs of mutations detected at both time-points (sAML to MDS/CMML stage) in each patient. We identified 4 different clonal dynamics: mutations that were initially present but increased VAF (type-1), decreased (type-2), were newly acquired (type-3) or persisted with similar allelic burden (type-4) at sAML stage. Interestingly, most of type-1 mutations were detected in *STAG2* gene. Thus, mutational burden of *STAG2* were markedly increased (6/8 patients) at sAML progression. Moreover, type-3 mutations, only detected at the sAML-stage, were predominantly identified in *FLT3* (3/4) and *NRAS* (5/6). Conversely, type-4 mutations were present in MDS-related genes such as *SRSF2* (9/12), *SF3B1* (3/6) and *TET2* (8/12). Most of mutations in these genes showed no changes during progression to sAML.
Summary/Conclusions: Progression from MDS to sAML could be explained by different mutational processes, as well as by the occurrence of unique and complex changes in the clonal architecture of the disease during the evolution. Mutations in genes such as *STAG2*, *FLT3* or *NRAS* could play an important role during disease progression.

PROGRESSION OF MDS TO AML FEATURES GAIN OF SINGLE DRIVER MUTATIONS WITH CONSEQUENT CHANGES IN CLONAL COMPOSITION AND OCCURRENCE OF MULTIPLE CLONES WITH MUTATIONS IN IDENTICAL GENES

J. Stosch[1,*], A. Heumüller[1], S. Bleul[1], C. Niemöller[1], M. Rothenberg-Thurley[2], N. Renz[1], J. Riba[3], K. Szarc vel Szic[1], D. Pfeifer[1], A. Nieters[4], S. Zimmermann[3],

[1]Department of Medicine I, Medical Center - University of Freiburg, Freiburg, [2]Department of Medicine III, University of Munich, Munich, [3]Department of Microsystems Engineering - IMTEK, University of Freiburg, [4]Center for Chronic Immunodeficiency, Medical Center - University of Freiburg, Freiburg, Germany

Background: Progression of myelodysplastic syndromes (MDS) to acute myeloid leukemia (AML) associates with acquisition of genetic aberrations. Similar aberrations may occur in the development of primary AML, particularly in the context of a clonal hematopoiesis of indeterminate potential. Thus, in-depth knowledge of the genetics and clonal composition of MDS and paired AML samples allows insights into MDS progression in particular and AML development in general.
Aims: Here, we assessed mutations in serial samples of patients with MDS and progression to AML by next generation (NGS) and single-cell sequencing to identify mutations and clonal changes associated with AML development.
Methods: Mononuclear cells from 21 bone marrow (BM) samples of 8 patients with MDS and progression to AML were studied for mutations by an NGS panel (Agilent HaloPlex, Illumina MiSeq) comprising 98 genes relevant in hematologic neoplasms, and for copy number variations (Affymetrix CytoScan HD). All AMLs had normal karyotype, except one with del(5q). Samples were collected during MDS, at AML diagnosis and under treatment. Variants were verified by Sanger- and pyrosequencing or fragment analysis in BM and CD3+ cells (germline). Clonal assignment of variants was verified by single-cell mutation analysis using a Single-Cell Printer.
Results: Applying predefined criteria and verifying variants by orthogonal methods in blasts and CD3+ cells, a median of 3 variants (range, 1-6) in the MDS and 4 (range, 1-6) in the AML samples were deemed pathogenic. During MDS, all patients except one had mutations in genes involved in RNA-splicing (*SF3B1*, *SRSF2, ZRSR2, U2AF1*) or epigenetic regulation (*TET2, IDH1, DNMT3A*, *ASXL1, EZH2*). Additional mutations existed in *FLT3, NRAS, PTEN, STAG2, CEBPA, RUNX1* or *WT1*. Subclonal mutations (i.e. variant allele frequency (VAF) <10%) were present in only two MDS samples. Towards AML, patients acquired a median of 1 (range, 0-2) new mutation in *FLT3, CSF3R, KRAS, NRAS, PHF6*, *IDH1* or *WT1*. The VAF shifts from MDS to AML indicated cooperativity of mutations on clonal outgrowth, *e.g.* gain of *CSF3R* p.T618I was accompanied by a chromosome 19q-loss resulting in hemizygosity of a preexisting *CEBPA* mutation; or acquisition of a *FLT3*-TKD mutation was associated with outgrowth of a *RUNX1* mutation. Changes in mutations or VAFs also occurred under treatment, *e.g.* in one patient, AML progressed under decitabine treatment by gaining two distinct *FLT3* mutations. In another patient, who achieved complete remission after induction chemotherapy, but relapsed with MDS, which again progressed to AML, mutations were lost or gained, while a *STAG2* mutation was detectable at all time. Interestingly, identical genes were recurrently mutated in different clones within single patients, *e.g.* progression to AML associated with acquisition of a *WT1* mutation in an *NRAS* mutated MDS clone and with the generation of further subclones harboring distinct combinations of different *WT1* and *NRAS* mutations. The co-occurrence of the specific *WT1* and *NRAS* mutations in the different clones was demonstrated by mutation analyses of 72 single patient cells.
Summary/Conclusions: Mutations in MDS are few in number, but enriched in genes involved in RNA-splicing or epigenetic regulation; gain of single driver mutations leads to clonal outgrowth and thus, AML. Subsequent treatment can change the mutational and clonal profile. Mutations in identical genes occur in different clones, as confirmed by single-cell analyses; this suggests a fertile ground (*e.g.* microenvironment) for such mutations in a patient and may lead to (a therapeutically exploitable) competition of clones.

PRECLINICAL MODELING OF MYELODYSPLASTIC SYNDROMES

K. Rouault-Pierre[1,*], S. Mian[1], M. Goulard[2], A. Abarrategi[1], A. Di Tullio[1], A. Smith[3], A. Mohamedali[3], S. Best[3], A.-M. Nloga[2], A. Kulasekararaj[3], L. Ades[2], C. Chomienne[2], P. Fenaux[2], C. Dosquet[2], G.J. Mufti[3], D. Bonnet[1]
[1]The Francis Crick Institute, London, United Kingdom, [2]Hopital Saint-Louis, Paris, France, [3]King's College London, London, United Kingdom

Background: Myelodysplastic syndromes are a heterogeneous group of clonal hematopoietic stem cell disorders with diverse phenotypes, characterized by ineffective hematopoiesis and bone marrow morphological dysplasia with varying risk of leukemic transformation. Over the last decade, there has been significant progress in understanding the pathogenesis underlying the MDS. Notably, patient derived xenograft (PDX) models offer the most advanced preclinical opportunity to capture the complexities of this myeloid malignancy. A number of different animal models have been proposed but the more promising to date are the NSG and the NSG-S (humanized with SCF, GM-CSF and IL-3).
Aims: Here we have used bone marrow cells from 39 MDS patients, covering all risk groups, to generate a preclinical *in vivo* and *in vitro* model, which could be used to study clonal evolution and test targeted therapies.
Methods: We have used NSG and NSG-SGM3 mice to assess the scid-repopulating capacity of the MDS stem cells in presence or absence of mesenchymal stromal cells (MSCs). Moreover we have developed an *in vitro* 2D co-culture system as an alternative/complementary tool to *in vivo studies.*
Results: Our data showed promising results with the injection of mononuclear cells obtained from patient BM, however the co-injection of mesenchymal stromal cells (MSCs) did not improve the level of engraftment. To address the question of the becoming of MSCs once injected, we tracked them back into the mice BM and showed that they disappeared after a week of engraftment. With a 2D *in vitro* system, we showed that we could co-culture CD34$^+$ cells from MDS patient BM, on auto- and allo-genic MSCs, over 4 weeks with a fold expansion ranging from 50 to 600 times. More importantly those cells conserved their clonal architecture and chromosomal aberrations.

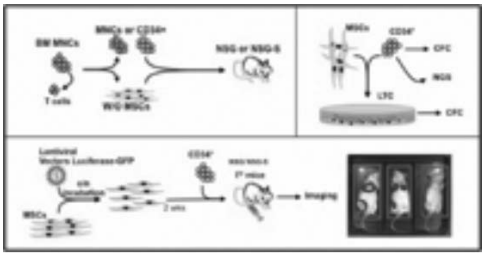

Figure 1.

Summary/Conclusions: Although the *in vivo* model cannot be replaced, the low level of engraftment of most of the patients is a limit in the study of MDS. Here we have demonstrated the value of the 2D co-culture system using MSCs (or murine MS5) as an alternative model to study MDS. This *ex vivo* culture system, which lasts for only 4 weeks and requires low number of human CD34$^+$ cells, provides a robust preclinical assessment model to test therapeutic effects of different drugs and other approaches on the MDS clonality and autologous MSCs prior to treatment of MDS patients.

Antonio e Biagio Hospital, Alessandria, [13]dept of Hematology, University of Florence, Florence, Italy

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of diseases characterized by a clonal and ineffective hematopoiesis, as well as the tendency to develop iron overload, mainly due to red blood cell transfusions. Iron overload has been described to increase ROS production and progressively worsen hematopoiesis. In mitochondria, iron is a fundamental component of cytochromes belonging to the oxidative phosphorylation (OXPHOS), which is considered the main source of cellular energy. Mitochondria are also the main site of ROS production." In this regard, cancer energetic metabolism is an emerging issue that could represent an attracting therapeutic target.
Aims: The aim of the study was to investigate the energetic metabolism in MDS patients and to understand the impact of iron overload on the energy production.
Methods: We selected 37 samples from patients with MDS with or w/o iron overload (7 RA, 5 RARS, 9 RCMD, 4 RAEB-I, 2 RAEB II and 10 s-AML). In addition we analyzed 86 samples from healthy subjects stratified according to age (20-103 years) and 4 samples from beta thalassemia with iron overload. In all these samples, we evaluated the ATP/AMP ratio, as marker of energy status, the OXPHOS activity, in term of oxygen consumption and ATP synthesis, the lactate dehydrogenase (LDH) activity, as marker of anaerobic glycolysis, and malondialdehyde (MDA), as marker of lipid peroxidation. The same parameters have been analyzed also after iron chelation with deferasirox (DFX) and after incubation of the cells with DFX and DFO
Results: Our study clearly demonstrated that mitochondrial function is altered in MDS, leading to a strong energetic defect and an increase in oxidative stress, far beyond the expected paraphysiological decrease resulting from ageing. The OXPHOS efficiency is highly reduced in MDS compared to controls, determining an impairment of the ATP/AMP ratio, which is 2.4 in young controls, 0.75 in elderly controls and it is 0.2 in b-thalassemia and MDS patients. By contrast, LDH activity increased in the MDS patients (6mU/mg) with respect

the controls (88 mU/mg), suggesting an attempt to compensate the energy unbalance with the increment of anaerobic glycolysis. MDA level, which reflects the lipid peroxidation, is 1mM in young subjects, 9mM in elderly subjects, 9mM in b-thalassemia and 15mM in MDS. In vitro iron chelation partially restored this abnormalities in MDS patients: ATP/AMP ration increases from 0.2 to 0.6 in MDS and b-thalassemia, by contrast it is reduced in healthy subjects from 2.4 to 1.6. Anaerobic glycolysis is reduced after DFX incubation, in fact LDH decrease from 88 to 77 in MDS. By contrast, in healthy samples the iron chelation determined a reduction of OXPHOS activity, with a consequent impairment of ATP/AMP ratio and an increment of anaerobic glycolysis flux. Lipid peroxidation is significantly reduced of 28% with DFX and 23% with DFO (p value <0.001 for both). Similar reduction is observed in b-thalassemia. By contrast MDA levels increased in healthy subjects incubated with DFX. Curiously, all these abnormalities are more pronounced in MDS with IOL compared to MDS w/o IOL and are significantly worse in MDS without IOL compared to elderly normal subjects. Finally, *in vivo* treatment of patients with DFX reproduces similar findings as *in vitro* incubation.

Summary/Conclusions: In summary OXPHOS activity and the energetic status are highly impaired in MDS compared to elderly subjects. MDS cells used O2 to produce ROS instead of ATP. This is typical of ageing but is significantly increased in MDS compared to elderly controls and it is further increased by IOL. DFX is able to restore mitochondrial activity and ATP production in all the patients analyzed after *in vivo* or *in vitro* treatment.

P659

V-SET AND IMMUNOGLOBULIN DOMAIN-CONTAINING 4 (VSIG4) EXPRESSED ON MONOCYTES INCLUDING TUMOR-ASSOCIATED MACROPHAGES SUPPRESSED ANTITUMOR IMMUNE RESPONSES IN MYELODYSPLASTIC SYNDROMES

Y. Kuribayashi-Hamada[1,*], H. Tamura[1], M. Ishibashi[1], T. Asayama[1], K. Moriya[1], I. Choi[2], K. Inokuchi[1]

[1]Department of Hematology, Nippon Medical School, Japan, Sendagi, Bunkyo-ku, Tokyo, Japan, [2]Department of Microbiology and Immunology, Inje University College of Medicine, Busan, Korea, Republic Of

Background: In myelodysplastic syndromes (MDS), blast cells increase with clonal proliferation during disease progression, while immune cells in the bone marrow (BM) microenvironment become less efficient. The V-set and immunoglobulin domain-containing 4 (VSIG4) molecule is a new B7 family-related protein and strong negative regulator of T-cell proliferation. However, the role of VSIG4 in tumors including hematological malignancies remains unknown.

Aims: We investigated the expression and functions of VSIG4 in MDS.

Methods: 1) Peripheral blood (PB) and BM samples were obtained from 39 patients with acute leukemia transformed from MDS (AL-MDS, N=21), MDS (N=13), and chronic myelomonocytic leukemia (CMML, N=5) and from healthy controls (N=14). The expression of VSIG4 in mononuclear cells (MCs) from the samples and MDS cell lines (F-36P and SKM-1) was analyzed with real-time PCR and flow cytometry (FCM). 2) After cultivation with BM stromal HS-5 cells, its culture supernatants (HS-5 sup.), immunomodulatory drugs (lenalidomide [LEN] and pomalidomide [POM]), and anti-MDS agents (cytarabine and azacitidine), VSIG4 expression on cells was determined using FCM. 3) The proliferative potential was examined by BrdU incorporation using FCM and the MTT assay. 4) The cytotoxic activity of natural killer (NK) cell line NK-92MI against target cells was determined by measuring lactate dehydrogenase activity in culture supernatants. The production of IFN-γ from donor T cells was measured in the cell culture supernatants using ELISA.

Results: 1) VSIG4 mRNA expression in PBMCs from patients with AL-MDS was significantly higher than in those from controls. Cell-surface VSIG4 expression on CD14+CD11b+ monocytes from MDS and AL-MDS patients was higher than in those from controls, but VSIG4 expression was not detected on CD34+ blasts. In CD14+CD11b+ monocytes of MDS and AL-MDS patients, VSIG4 was strongly expressed on CD68+CD206+ tumor-associated macrophages (TAMs). Furthermore, the expression levels of VSIG4 on CD14+ monoblasts from CMML patients were significantly upregulated in comparison with those from controls. 2) Two MDS cell lines expressed both VSIG4 mRNA and its cell-surface protein. VSIG4 expression on MDS cell lines, and on monocytes and monoblasts from MDS and CMML patients, respectively, was significantly upregulated by co-cultivation with HS-5 sup, LEN, and POM, but not with cytarabine or azacitidine. 3) VISG4+ MDS cells had higher proliferative potential than VISG4– cells, and the proliferation of VSIG4+ cells was suppressed by VSIG4-specific small interfering RNA. 4) LEN-treated K562 cells, which induced high VSIG4 expression, were more resistant to NK-mediated cytotoxicity than untreated K562 cells. The cytotoxic activity of NK cells was inversely correlated with the expression levels of VSIG4 on target cells. CD45-mediated ADCC activity of NK92-MI cells against LEN-treated MDS cells was inhibited in comparison with untreated cells. Moreover, the production of IFN-γ from donor T cells co-cultivated with LEN-treated MDS cells was suppressed compared with control cells.

Summary/Conclusions: Our study demonstrated that VSIG4 was highly expressed on monocytes including TAMs in MDS and AL-MDS patients, and on monoblasts in CMML patients. VSIG4-expressing monocytes and monoblasts may suppress antitumor immune responses and be associated with disease progression in MDS and CMML. The results will allow us to elucidate the function of VSIG4 in MDS pathophysiology and lead to the development of new immunotherapy.

TRANSCRIPTOME ASSESSMENT OF DNA REPAIR GENES IN CHRONIC MYELOMONOCYTIC LEUKEMIA: SYNTHETIC LETHALITY TARGETS

A.M. Hurtado López[1,*], G. Luengo Gil[1], T. Chen[1], L. Palomo[2], E. Lumbreras[3], E. Caparrós [1], B. Przychodzen[4], M.L. Amigo[1], M. Díez-Campelo[3], L. Zamora[2], F. Ortuño[1], V. Vicente[1], J. Maciejewski[4], C. del Cañizo[3], F. Solé[2], F. Ferrer-Marin[1], A. Jerez[1]

[1]Hematology and Medical Oncology Department, Hospital Morales Meseguer, IMIB, Murcia, [2]Josep Carreras Leukaemia Research Institute, ICO-Hospital Germans Trias i Pujol, Universitat Autònoma de Barcelona, Barcelona, [3]Department of Hematology, Hospital Universitario de Salamanca, Salamanca, Spain, [4]Department of Translational Hematology and Oncology Research, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, USA, United States

Background: Though genetic instability is a hallmark of myeloid disorders, the lack of recurrent somatic mutations, inarguably pathogenic, in the DNA repair machinery have precluded a predominant interest in this pathway. However, the recent discovery of non classical leukaemogenesis by splicing defects, the paramount influence of epigenetic anomalies, and the development of of unbiased high-throughput sequencing approaches oblige us to revisit those routes in blood cancers.

Aims: To perform improved massive RNA-seq in chronic myelomonocytic leukemia (CMML) samples to identify neoplasm-specific targets for a synthetic lethality therapeutic aproach. To validate the candidates through a direct strategy in an extended cohort of CMML, myelodisplastic sydromes (MDS) and acute myeloid leukemia (AML) patients.

Methods: We performed enhanced RNA-seq on 27 CMML bone marrrow samples at diagnosis and 10 healthy BM samples We validated those DEGs by RT-PCR in an extension cohort of 73 additional CMML patients and assessed their potential singular pattern in this disease by analyzing 80 MDS and 90 AML patients. We further chose 13 of the diferentially expressed genes for validation and characterization through the myeloid spectrum based on clinical considerations: i) druggable oncogenes found to be highly overexpressed in our cmml patients or allowing for the inhibition of an specific DNA repair pathway (i.e. XPA, XRCC4, MSH4): ii) oncogenes infra-expressed in our cohort but with inhibitory molecules already being tested in myeloid neoplasms (i.e. PARP1).Global pattern of DNA repair gene expression was compared with MDS and AML MILE study data.

Results: Of 27 CMML patients and 10 healthy donors, the expression of 18 genes was significantly different between the two groups (p-value<0.05) with 6 genes up-regulated and 12 genes down-regulated in CMML patients compared with donors. Defects on genes predominantly unique to a single strand breaks repair pathway included: NEIL1 and OGG1 in base excision repair (BER), XPA and MSS19 in nucleotide excision repair (NER) and MSH4 in Mismatch Repair (MMR). Only XRRC4 overexpression was found as a significant defect in genes associated exclusively to double strand break repairs. We found different directions of misregulation in our DNA repair genes candidates in CMML when we validated them by RT-PCR in an extended cohort of 73 CMML, 80 MDS and 90 AML patients (i.e. PARP1 is down-regulated in our CMML and up-regulated in our complex-karyotype AML subset). To validate this, we extracted the DNA repair transcriptional components from a large dataset of 206 MDS, 47 complex karyotype AML (AMLcx) and 73 healthy donors bone marrow from the MILE study. Surprisingly, MDS misregulation was characterized for a predominance of upregulated genes (14 out of the 20 misregulated targets) while AMLcx showed a global defect with a predominance of downregulation (37 out of 50 misregulated targets). Of note, some genes showed opposite sense of misregulation according to the myeloid disorder: TDP1 was upregulated in CMML cases and downregulated in AMLcx, and viceversa for BAP1. CDK1 and EXO1 were upregulated in MDS cases and the opposite effect was found among AML cases.

Summary/Conclusions: Using an unbiased and massive DNA repair transcriptome assessment, we have identified a series of candidate targets for a synthetic lethality approach in CMML. In addition, the different sense of misregulation of these and other targets within the myeloid diseases, some of them already being targeted in the clinical trial setting, emphasize the need of a neoplasm-personalized test of DNA repair modulators.

P661

DIFFERENTIAL DIAGNOSIS BETWEEN MYELODYSPLASTIC SYNDROMES AND NON-CLONAL CYTOPENIAS BY FLOW CYTOMETRY ANALYSIS USING A MYELOID MATURATION DATABASE

M.T. Cedena[1,*], F. Mirás[1], R.M. Ayala[1], E. Martín-Clavero[1], M.L. Paciello[1], J. Martínez-López[1]

[1]Hematology, H. 12 Octubre, Madrid, Spain

Background: The diagnosis of myelodysplastic syndromes (MDS) is based

on cytomorphological characteristics, but it remains a challenge in some patients who do not fulfil diagnostic criteria. Flow cytometry (FC) immunophenotyping can be in an important tool for MDS diagnosis, but a lack of standardisation and subjectivity of the analysis hinder its applicability.
Aims: To develop a methodology for FC immunophenotyping that allows us to stablish the differential diagnosis between MDS patients and non-clonal cytopenias using a myeloid maturation database.
Methods: Bone marrow samples from 55 MDS patients, and 51 controls with cytopenias of several origins (immune disease, hypersplenism, drug toxicity) were analysed by FC. We elaborated a Myeloid Maturation Database using the *Infinicyt*® v1.7 software (*Cytognos*, Spain). From all bone marrow controls, we merged files stained with a 4-colour combination (CD16-FITC/CD13-PE/ CD45pCP/ CD11bAPC). We selected myeloid population from the merged file and drew a maturation path. We obtained a maturation diagram that displays the fluorescence intensity of each parameter measured along the maturation stages. Then, for patients and controls, we obtained the fluorescence intensities whose median values exceeded ±2SD range in comparison with the stored database values (Figure 1). We elaborated a score, considering the relevant changes in fluorescence intensities (deviations) in the four markers analysed (CD16, CD13, CD45, CD11b) and in the four maturation stages, with a punctuation from 0 to 16.
Results: We found a mean of 1.9 deviations (fluorescence intensities values exceeded ±2SD) in controls, and a mean of 4.5 deviations in patients. Our test resulted reliable for differential diagnosis between controls and patients (curve ROC analysis, AUC=0.748; *p= 0.016*). We found that with a cut-off of 4.5 deviations, we obtained a high specificity in the diagnosis of MDS (100%) but a low sensitivity (45%). With a high suspicion of MDS (specificity 90%), we can consider patients with scores above 3.5, thus achieving higher sensitivity (59%). Additionally, the number of immunophenotyping changes correlated well with prognostic risk. We confirmed that the higher the risk, the greater impact on deviations from the normal pattern (average of 3.7 at low risk, 4.5 at intermediate risk; 6.8 at high risk) (Figure 2).

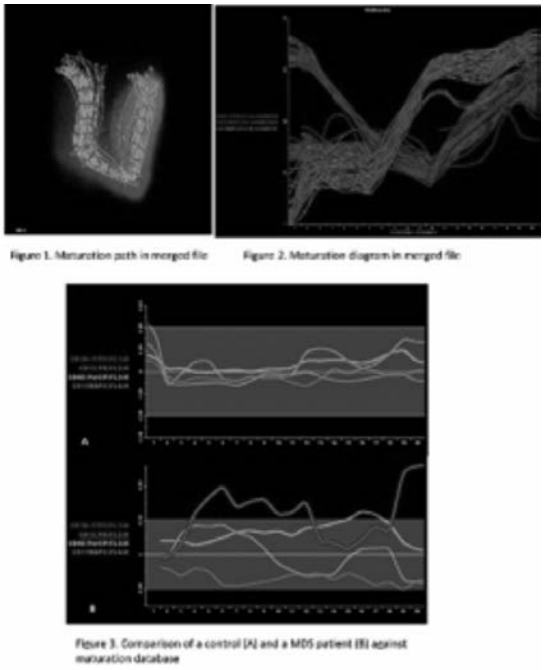

Figure 1.

Summary/Conclusions: The maturation database (using the maturation analysis from *Infinicyt*® software) was useful to discriminate between MDS patients and non-clonal cytopenias, proving to be a reliable diagnostic test, also with prognostic implications. The application of this database as a diagnostic tool has the advantage that the result is independent of the observer. Inclusion of more myeloid markers and incorporation of erythroid parameters could increase sensibility in differential diagnosis.

Myelodysplastic syndromes - Clinical 2

P662

A PHASE IB STUDY EVALUATING THE SAFETY AND CLINICAL ACTIVITY OF ATEZOLIZUMAB ALONE AND IN COMBINATION WITH AZACITIDINE IN PATIENTS WITH RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES

A.T. Gerds[1,*], B.L. Scott[2], P. Greenberg[3], A. Verma[4], P. Phuong[5], M. Yan[6], M. Dail[5], C. Green[5], C. Li[5], K. Krishnan[5], W. Donnellan[7]
[1]Cleveland Clinic, Cleveland, [2]Fred Hutchinson Cancer Research Center & University of Washington, Seattle, WA, [3]Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA, [4]Department of Oncology, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York, NY, [5]Genentech, Inc., South San Francisco, CA, United States, [6]Hoffmann-La Roche Ltd., Mississauga, ON, Canada, [7]Tennessee Oncology, Nashville, TN, United States

Background: Treatment options are limited and prognosis is poor for patients (pts) with relapsed or refractory myelodysplastic syndromes (R/R MDS), those who relapse after or fail to achieve complete response with hypomethylating agents (HMAs). Atezolizumab (atezo) is a humanized IgG1 monoclonal antibody that binds programmed death-ligand 1 (PD-L1), disrupting the immune activation checkpoint. The role of PD-L1 blockade in hematologic disorders is not yet established. Immune evasion via the PD-L1/PD-1 pathway may play a role in MDS resistance to HMA treatment (Yang et al. *Leukemia.* 2014). Upregulation of PD-L1 expression seen in pts during and after HMA treatment suggests that atezo could provide benefit in HMA-exposed pts as a single agent or in combination with an HMA.
Aims: To determine the safety and clinical activity of atezo alone and in combination with azacitidine (aza) in an open-label Phase Ib clinical trial (NCT02508870).
Methods: Pts with R/R MDS were eligible for Cohorts A and B, excluding those with prior solid organ or allogeneic hematopoietic cell transplant. Pts in Cohort A received atezo 1200mg intravenously (IV) on day 1 of each 21-day cycle for up to 17 cycles. Pts in Cohort B received aza 75mg/m^2 on days 1 through 7 and atezo 840mg IV on days 8 and 22 of each 28-day cycle for 6 cycles, followed by single-agent atezo 1200mg IV on day 1 of each 21-day cycle for up to 8 cycles. Primary endpoints were safety and tolerability. Secondary endpoints included overall response rate, time to AML progression, PFS, OS and changes in transfusion rate. Blood and bone marrow samples were collected for PK evaluation and biomarker analysis.
Results: At the time of data cutoff, 10 pts in Cohort A and 6 pts in Cohort B were safety evaluable. The median age was 76 years (range, 63-89 years); 4 of 16 pts (25%) had ≥2 previous lines of therapy. All pts were previously exposed to aza, and 2 of 16 pts (13%) were also exposed to decitabine. 15 of 16 pts were refractory to prior therapy. All pts experienced ≥1 treatment-emergent adverse event (AE). The most common Grade 3-4 AEs were febrile neutropenia (31%) and decrease in neutrophil count (25%). One pt died on study of an unknown cause. The median duration of treatment was 101 days (range, 70-275 days) in Cohort A and 92.5 days (range, 39-144 days) in Cohort B. Four of 10 pts in Cohort A and 3 of 6 pts in Cohort B remained on study as of 16 Sep 2016. All 10 pts in Cohort A and 5 of 6 pts in Cohort B were evaluable for response. No pt achieved an objective response; 6 of 10 pts (60%) in Cohort A and 3 of 5 pts (60%) in Cohort B had stable disease. Compared with pretreatment, a trend toward decreased RBC transfusions was observed in pts in Cohort A, especially in those who remained on therapy beyond 12 weeks. Preliminary PK analysis showed that exposure to atezo as a single agent or in combination with aza was comparable to historical data in pts with solid tumors.
Summary/Conclusions: Early evaluation of atezo alone and in combination with aza suggests that the safety profile is consistent with that expected in the study population. Additionally, the duration of therapy observed is encouraging in this R/R population with no standard-of-care options. Updated safety, efficacy and survival data will be presented. Emerging correlative biomarker information will also be discussed.

P663

EPIGENETIC DRUG TREATMENT GLOBALLY INDUCES CRYPTIC TRANSCRIPTION START SITES ENCODED IN LONG TERMINAL REPEATS (LTRS)

Background: Epigenetic drugs are currently used for the treatment of several hematologic malignancies, but their pharmacological mechanism remains poorly understood. For DNA methyltransferase and histone deacetylase inhibitors (DNMTi and HDACi) several mechanisms of action have been proposed, mainly based on candidate gene approaches. However, less is known about their genome-wide transcriptional and epigenomic consequences.
Aims: To investigate the effects of epigenetic treatment on transcription and chromatin, we profiled genome wide transcription start sites (TSS) activities and associated chromatin changes following the treatment with inhibitors against DNMTs, HDACs, or both.
Methods: Genome wide analysis of transcription start sites (TSS) (Cap analysis of gene expression (CAGE) sequencing), methylation status (whole-genome bisulfite sequencing) and chromatin dynamics (Chromatin-immunoprecipitation (ChIP) sequencing) were done by using a previously described reporter cell line model. Functional assays were used to investigate the mechanisms of LTR reactivation, a neuroblastoma mouse xenograft model to confirm the LTR reactivation in vivo.
Results: Following the treatment with inhibitors against DNMTs, HDACs, or both, we observed the activation of thousands of cryptic, currently non-annotated transcription start sites (treatment-induced non-annotated transcripts, TINATS). These TINATs arose most commonly from LTR12 elements, particularly LTR12C (ca. 50% of all TINATs). The resulting transcripts frequently splice into protein-coding exons and encode truncated or chimeric open reading frames which translated into currently uncharacterized protein isoforms with predicted abnormal functions or immunogenic potential, the last one based on their foreign sequence and capability of being presented on MHC-class I molecules. TINAT transcription after DNMTi coincided with DNA hypomethylation and gain in H3K4me3, H3K9ac, and H3K27ac, and further activating histone marks, while HDACi specifically induced a subset of TINATs in association with H2AK9ac, H3K14ac, and H3K23ac. Despite this mechanistic difference, both inhibitors convergently induced transcription from identical sites since TINATs are encoded in solitary long-terminal repeats of the endogenous retrovirus-9 family, epigenetically repressed in virtually all normal cells. Moreover, we found a consensus GATA2 binding motif which strongly distinguished LTR12Cs with TINATs from LTR12Cs without TINATs, supporting that GATA2 is likely the upstream transcription factor responsible for TINAT activation. Knock-down of GATA2 resulted in a reduced LTR12C expression despite epigenetic drug treatment. Overexpression of LTRs in our cell line model showed reduced cell viability in 3 out of 10 TINAT candidates. The reactivation of LTR12C elements upon epigenetic drug treatment could be confirmed in other malignant cell lines as well. Importantly, treatment with several chemotherapeutic agents did not affect LTR12C transcript levels, suggesting that their induction is a specific effect of epigenetic modulation rather than a general consequence of cellular stress. Additionally, we measured the transcription of LTR12C transcripts after SAHA treatment in a neuroblastoma mouse xenograft model, thereby confirming LTR12C induction *in vivo*.
Summary/Conclusions: DNMTi and/or HDACi induce *de novo* transcription of LTRs (LTR12 family), resulting in numerous fusion transcripts that encode novel protein isoforms which partly have the potential to influence cell proliferation, might explain the priming effect of epigenetic therapy and will be further investigated regarding their role as potential marker for epigenetic treatment response. Other future experiments will include proteomic approaches combined with T-cell cytotoxicity assays to further shed light on the interaction between epigenetic and immune therapy and the role of ERV-derived antigen presentation.

P664

LYMPHOPENIA IS AN INDEPENDENT RISK-FACTOR IN PATIENTS WITH LOW-RISK MDS ACCORDING TO THE IPSS-R

T. Silzle[1,*], E. Schuler[2], B. Hildebrandt[3], S. Blum[4], R. Haas[2], U. Germing[2]
[1]Oncology/Haematology, Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [2]Department of Haematology, Oncology and Clinical Immunology, [3]Institute of Human Genetics, University Hospital Düsseldorf, Düsseldorf, Germany, [4]Département d'oncologie, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland

Background: Lymphopenia is associated with an increased mortality in different medical conditions, including solid tumours and lymphoma. Little is known about its prognostic impact in myelodysplastic syndromes (MDS).
Aims: To clarify the prognostic impact of lymphopenia in MDS in addition to the Revised International Prognostic Scoring System (IPSS-R)
Methods: The Düsseldorf MDS-registry was searched for patients with a complete differential blood count at diagnosis. Patients having received allografting or with an absolute lymphocyte count >5.0 G/l were excluded. The influence of the absolute lymphocyte count at diagnosis on overall survival was determined by Kaplan-Meier analysis. Multivariate Cox regression analyses were performed.
Results: 2035 patients (RA n=182, RCMD n=978, RARS n=170, MDSdel5q n=92, RAEB-1/2 n=613) with a median follow-up of 23 months (mo) were identified. Data were sufficient for IPSS-R calculation in 651 patients. The mean absolute lymphocyte count (ALC) in the whole population was 1402/µl (95% *CI* 1368-1437, range 0.12-4972) with no significant differences between the IPSS-R groups (very low-risk [n=77] mean 1471/µl, low-risk [n=255] mean 1406/µl, intermediate-risk [n=154] mean 1244/µl, high-risk [n=96] mean 1419/µl, very-high risk [n=69] mean 1255/µl, p=0.067). 688 patients (34%) were lymphopenic (ALC < 1000/µl) with a significantly shorter survival (median 33.7 *versus* 26.4 months, Log Rank p < 0.001). After stratification according to IPSS-R, survival of lymphopenic patients was not significantly different in the very-low, intermediate or (very) high risk group. Within the low risk group the survival difference was of borderline significance (median 67 *vs* 47 months, Log Rank p=0.1, Breslow p=0.039). With an ALC above the first quartile of the whole population (850/µl) as discriminator, the survival difference between lymphopenic and non-lymphopenic patients within the IPSS-R low-risk group reached statistical significance (survival median 67.4 versus 43.0 months, Log Rank p= 0.002). This was not the case in the other IPSS-R subgroups. In multivariable analyses, an ALC <850/µl retained its independent prognostic value for the IPSS-R low risk group after inclusion into a Cox regression model together with age <>70 and LDH <> normal value (240 U/l) (p= 0.039). Patients with an ALC <850/µl had significantly lower platelet (median 97 *versus* 150 G/l, p<0.001) and neutrophile (median 1478 *versus* 1971/µl, p <0.001) counts but similar haemoglobin levels (median 9.1 *versus* 9.4 g/dl, p=0.052).
Summary/Conclusions: An absolute lymphocyte count < 850/µl is an independent risk factor in patients with low risk MDS according to the IPSS-R. Whether lymphopenia in MDS is a direct consequence of the underlying haematopoietic stem cell defects or arises from immune-modulating stimuli related to the disease or to other host conditions remains to be elucidated. The lower levels of platelets and neutrophils in lymphopenic patients observed in our cohort point towards an association of lymphopenia with marrow insufficiency. In addition, further studies with larger patient cohorts are necessary to define the lymphocyte count most suitable for prognostication.

P665

IMPACT OF MARROW COMPLETE RESPONSE IN THE NATURAL HISTORY OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) AND CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) TREATED WITH HYPOMETHYLATING AGENTS

A. Alfonso Pierola[1,*], G. Montalban-Bravo[1], K. Takahashi[1], E.J. Jabbour[1], T. Kadia[1], F. Ravandi[1], J. Cortes[1], C. DiNardo[1], N. Daver[1], G. Borthakur[1], N. Pemmaraju[1], M. Konopleva[1], C. Bueso-Ramos[2], S. Pierce[1], H. Kantarjian[1], G. Garcia-Manero[1]
[1]Leukemia, [2]Hematopathology, MD Anderson Cancer Center, Houston, United States

Background: The concept of marrow complete response (mCR) was included for the first time in the 2006 International Working Group (IWG) response criteria in MDS. mCR is defined as a reduction to ≤5% myeloblasts and decrease by ≥50% compared to baseline with persistent cytopenias. However, their inclusion in the response criteria remains controversial as it is not known how it affects the natural history of MDS.
Aims: The aim of our study was to describe the impact of mCR in survival outcomes in patients with MDS treated with hypomethylating agents (HMA).
Methods: We retrospectively reviewed 713 patients diagnosed with MDS or CMML and treated with frontline HMA between 2004 and 2015 at a single institution. Clinical and demographic data were obtained from an electronic database. Response was assessed by modified 2006 IWG criteria. Statistical analyses were performed with the IBM SPSS Statistics 23.0 software. All tests were 2-sided with significance set at p<0.05.
Results: 444 (62.3%) patients from the initial cohort achieved at least hematologic improvement (HI) as best response and were included in the analysis. 162 (37%) patients were female. Median age at diagnosis was 68 years (range 17-91). Following the 2016 WHO classification: 30 patients (7%) were MDS-SLD, 50 (11%) MDS-MLD, 20 (5%) MDS-RS, 230 (52%) MDS-EB, 10 (2%) MDS-U and 104 (23%) CMML. According to the International Prognostic Scoring System (IPSS), 37 patients (8%) belonged to the low risk group, 176 (40%) to the intermediate-1 risk group, 198 (45%) to the intermediate-2 risk group, and 31 (7%) to the high risk group. 200 (45%) patients received azacitidine-based therapies and 244 (55%) decitabine-based therapies. Responses included: 238 (33% of the total population) complete responses (CR), 61 (9%) mCR, 2 (<1%) partial responses (PR) and 143 (20%) stable disease (SD). HI was observed in 410 (58% of the total population) of the patients. The median time to response was 3 cycles (range 1-24). Median overall survival (OS) since the

start of treatment was 21 months (95%CI=19-24): CR: 25 months (CI95%=20-30); PR: 27 months; mCR: 20 months (CI95%=20-30); and SD: 17 months (CI95%=14-19) (p=0.006). We compared OS between mCR *vs* CR (p=0.193, HR 0.796 [95%CI=0.765-1.122]), mCR *vs* PR (p=0.572; HR =0.564 [95%CI=0.078-4.105]) or mCR *vs* SD (p=0.243; HR=1.242 [95%CI=0.863-1.788]), without any statistical difference (Fig. 1A). Median progression-free survival (PFS) was 14 months (95%CI=13-16): CR: 16 months (CI95%=13-21); PR: 11 months; mCR: 10 months (CI95%=5-15); and SD: 10 months (CI95%=9-12) (p=0.013). No statistical differences were observed between PFS in patients who achieved mCR *vs* PD (p=0.410; HR 1.816 [95%CI=0.439-7.512]) and SD (p=0.7743; HR 1.059 [95%CI=0.752-1.491], but PFS was increased in those patients who achieve CR when compared to mCR (p=0.013; HR 0.665 [95%CI=0.482-0.918]) (Fig. 1B).

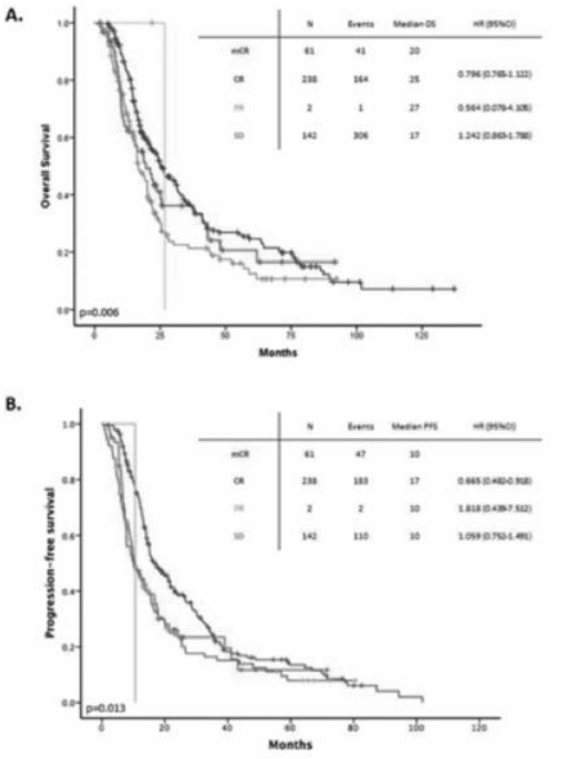

Figure 1.

Summary/Conclusions: Although mCR and CR result in the same OS, PFS is increased in patients achieving CR when compared with mCR. These data indicate that mCR should be considered as a valid endpoint in clinical trials.

P666

LUSPATERCEPT INCREASES HEMOGLOBIN AND REDUCES TRANSFUSION BURDEN IN PATIENTS WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES (MDS): LONG-TERM RESULTS FROM PHASE 2 PACE-MDS STUDY

A. Giagounidis[1,*], U. Germing[2], K. Götze[3], P. Kiewe[4], T. Wolff[5], K. Mayer[6], J. Chromik[7], M. Radsak[8], D. Wilson[9], X. Zhang[9], A. Laadem[10], M.L. Sherman[9], K.M. Attie[9], P.G. Linde[9], U. Platzbecker[11]

Background: Management of anemia is a common therapeutic challenge in patients (pts) with MDS. Luspatercept (ACE-536), a fusion protein containing modified activin receptor type IIB, is being developed for treatment of anemia in lower-risk MDS. Luspatercept binds to select TGF-β superfamily ligands (such as GDF11) reducing aberrant Smad2/3 signaling and promoting late-stage erythroid differentiation and increased hemoglobin (Hgb) levels (Suragani R, Nat Med, 2014; Attie K, Am J Hematol, 2014).
Aims: This ongoing, phase 2, multicenter, open-label study followed by a long-term extension (ext) study evaluates the effects of luspatercept in pts with lower-risk MDS. Endpoints include long-term safety and tolerability, erythroid response (IWG HI-E), RBC transfusion independence (RBC-TI, ≥8 weeks), duration of HI-E, pharmacodynamic and iron metabolism biomarkers, and pt-reported quality of life (QoL).
Methods: Inclusion criteria: MDS IPSS low or int-1, age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), no prior HMA, and no current lenalidomide or erythropoiesis-stimulating agent (ESA). The dose-escalation phase of the study is completed. An expansion cohort of up to 56 patients was added to this phase 2 study to evaluate response to luspatercept in pts who would not qualify for the phase 3 MEDALIST trial (for regularly transfused ring-sideroblast positive [RS(+)] patients with EPO >200 U/L). These include pts with low transfusion burden (LTB, <4U RBC/8 weeks) and either 1) RS(+) (≥15% in bone marrow) with baseline EPO ≤200 U/L or 2) RS(-) and any EPO level. RS(-) pts were allowed up to 6U RBC/8 weeks. Pts are treated every 3 weeks subcutaneously for up to 5 doses (titration up to 1.75mg/kg) in the base study (NCT01749514) and are then eligible for long-term treatment up to 5 additional years (NCT02268383).
Results: Data (as of 09Sept2016) were available for 73 base and 42 ext study pts. 32 base and 22 ext pts were LTB; 41 base and 20 ext pts were high transfusion burden (HTB, ≥4U RBC/8 weeks). Median (range) age (yr) was 72 (27-90), 53% pts had prior ESA, 51% pts had baseline EPO <200 U/L. Median (range) Hgb (g/dL) for LTB pts was 8.6 (6.4-10.1). Median (range) RBC transfusion burden (U/8 weeks) for HTB pts was 6 (4-18). 71% base and 86% ext pts were RS(+). IWG HI-E response rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 62% (18/29) and 83% (19/23) for RS(+) pts with EPO <200 U/L and 46% (5/11) and 88% (7/8) for RS(+) pts with EPO 200-500 U/L. RBC-TI rates for pts treated with ≥0.75mg/kg in the base and ext studies, respectively, were 68% (13/19) and 71% (10/14) for RS(+) pts with EPO <200 U/L and 33% (3/9) and 60% (3/5) for RS(+) pts with EPO 200-500 U/L. Preliminary RS(-) response rates (IWG HI-E and RBC-TI) by subgroup will also be presented at the meeting. Luspatercept was well tolerated, with related grade 3/serious adverse events (in 3 pts) as of 28Nov2016 of blast cell count increase, myalgia, and worsening of general condition. The most common related AEs (≥2 pts) were diarrhea, fatigue, headache, hypertension, arthralgia, bone pain, injection site erythema, myalgia, and peripheral edema.
Summary/Conclusions: Lower-risk MDS patients treated long-term with luspatercept demonstrated robust and sustained increases in Hgb and decreases in transfusion burden and a high rate of RBC-TI. A Phase 3 study of luspatercept in regularly-transfused RS(+) patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; NCT02631070).

Background: Azacytidine (AZA) is the current standard of care for patients with high-risk myelodysplastic syndrome (MDS) in Europe. AZA has shown a

survival advantage when compared with conventional therapies and has also shown activity in IPSS lower-risk patients. However, about 40% of patients do not respond and most patients loose response within 2 years. Treatment options for MDS patients failing hypomethylating agents therapy are scarce and overall survival (OS) is extremely short.

Aims: Objectives of this study were to describe in a cohort of real life MDS patients treated with AZA, the reasons causing treatment discontinuation, and to evaluate the clinical outcome after the end of AZA therapy.

Methods: Unselected patients recorded in the MDS Registry of Fondazione Italiana Sindromi Mielodisplastiche (FISM) and treated with AZA from January 2009 to June 2014 were considered for the analysis. All types of conventional published schedules of AZA were allowed. Clinical response, cause of discontinuation, salvage treatments and OS from discontinuation of AZA were the major end points.

Results: Between January 2009 to June 2014 1799 newly diagnosed MDS patients were enrolled in the Registry, and 418 received AZA; 269 as 1st line treatment (64%), 115 as 2nd line treatment (28%), and 34 as a line ≥3rd (8%). Median age was 73 years (range 18-91); 260 patients (62%) were male. WHO diagnosis was RA or RARS (n=27, 6%), RCMD with or without RS (n=62, 15%) AREB-1 (n=126, 30%), AREB 2 (n=189, 45%), other subtypes (n=15, 4%). At start of AZA therapy IPSS score was low in 14 (3.4%), int-1 in 97 (23.2%), int-2 in 183 (43.8%), high in 67 patients (16%), and not available in 57 patients (13.6%). Patients received a median of 7 courses of treatment (range 1-63). Seventy-three % of the whole cohort (418 pts) were alive at 1 year from beginning of AZA therapy and median OS was 23 months, (25 for IPSS lower-risk MDS and 21 for IPSS higher risk MDS). OS after discontinuation of AZA was 8 months. Clinical responses according to IWG criteria were available in 344/418 patients (82%): 45 (13%) patients achieved a complete hematological response, 77 (22%), a partial response, 86 (25%) had stable disease while 136 (40%) did not respond. Response was achieved after a median of 6 cycles. After a median follow up of 16 months (range 7-35) in 37 (9%) patients AZA therapy was still ongoing while in 381 (91%) the treatment has been discontinued. Interruption of treatment was due to loss of response in 59 (16%) patients, AML evolution in 154 (40%), death in 43 (11%), toxicity or poor compliance in 39 (10%), allogeneic transplant (HSCT) in 12 (3%), other reasons in 22 (6%), not reported in 52 patients (14%). Of the 381 patients who discontinued AZA, 15 (4%)were managed with intensive AML-like chemotherapy, 22 (6%), received an allogeneic HSCT, 27 (7%) low-dose chemotherapy (7%), 22 (6%) erythroid stimulating agents,18 (5%) other treatments and 277(72%) patients no further treatment or only supportive therapy.

Summary/Conclusions: Our data confirm that AZA therapy is effective for MDS patients, both with higher and lower IPSS risk disease. Response rate is consistent with what previously reported, with a median OS of 23 months. Interestingly, at 16 months, 91 % of patients had discontinued treatment, either for progression or loss of response and only in 10% of cases for reported toxicity. Only 28% of patients received any kind of salvage therapy and overall survival after AZA discontinuation was poor (8 months).

P668

COMBINATION OF DEEP PHENOTYPING AND TARGETED NEXT GENERATION SEQUENCING AS A DIAGNOSTIC TOOL IN CHILDREN WITH SUSPECTED MDS

Background: Paediatric Myelodysplastic Syndromes (MDS) are a rare and heterogeneous group of disorders distinct from adult MDS. They may present with symptomatic anaemia, life threating infection or evolving leukaemia; however, they may also present as unexplained cytopenias or with multisystem disease of unclear aetiology. Diagnosis can represent a huge challenge for clinicians, even in highly specialised centres and this can delay the delivery of the most appropriate treatment. Hence an accurate diagnosis is crucial in selecting the most appropriate management, including surveillance and follow up.

Aims: To devise a clinical grade diagnostic targeted NGS panel and combine the results with extensive clinical phenotypic information to obtain a diagnosis in children referred with suspected MDS.

Methods: Children (0- 18yrs) were referred from 14 UK centres with a diagnosis of suspected MDS and/or sustained cytopenias with morphological features of myelodysplasia. Extensive phenotypic information including family history, detailed clinical examination and disease course details were collected and captured on an online database using the Human Phenomiser tool. A customised targeted NGS panel was designed using the Illumina design studio containing 32 genes, 916 amplicons and 301 exons; selected through literature reports and well described mutations in Paediatric MDS and potential overlap Bone Marrow failure syndromes (BMFS). Coverage of each base within target regions was assessed for every sample on each sequencing run using Covermi software. Library preparation was performed using an Illumina Truseq Custom Amplicon panel, followed by sequencing on an Illumina MiSeq. Data analysis was performed using our established bioinformatic pipelines (Hamblin A: Blood 2014 124:2373)

Results: In total 59 patients (females= 29, males 30) have been screened and 3 subgroups identified based on the original suspected clinician diagnosis at presentation: MPN/JMML (n= 15), *de novo* MDS (n=9) and idiopathic cytopenias of undetermined significance, (ICUS) with some features of dysplasia (n= 35). Mutations were detected in 24/59 patients (40%, Table 1). Of these, NGS results confirmed the original clinical diagnosis in 15 cases (62.5%); established the diagnosis for the first time in 6 cases (25%); and led to a change in diagnosis (from autoimmune neutropenia to Shwachman-Diamond Syndrome) in 1 case leading to a significant change in patient management. In two already known cases, it allowed monitoring of the disease molecular signature. As expected, *RAS* pathway mutations were common in the JMML/MPN (100%) and *de novo* MDS patient subgroups (33%). Additional mutations in epigenetic modifiers, splicesome mutations as well as second *RAS* pathway hits were also detected in 40% of JMML patients and in one case within the *de novo* MDS group; this finding was associated with poor outcome. Within the heterogenous ICUS patient group, pathogenic mutations were identified in 5/35 (14.3%) cases with BMFS genes (*SBDS, ELANE, TP53*). In contrast to the other MDS/MPN cases, in this group, no *RAS* pathway mutations were detected.

Summary/Conclusions: Targeted NGS together with detailed phenotyping is a useful tool for the diagnosis of suspected MDS and unexplained cytopenias in children, with 40% of patient showing a disease-associated mutations. Results were available within 6-8 weeks in most cases enabling both rapid initial diagnosis and, in some cases, appropriate molecular markers for monitoring of clonal evolution and response to therapy. For the children who remain without a clinical diagnosis, whole genome sequencing (WGS) may identify pathogenic mutations and this is currently underway.

Myeloma and other monoclonal gammopathies - Clinical 3

Background: The role of autologous stem cell transplantation (ASCT) as first line therapy for newly diagnosed (ND) patients with multiple myeloma (MM) remains under evaluation given the deep responses to novel induction regimens. Outcomes for those not proceeding to ASCT following induction remain unclear, likely to be influenced by genetic risk and response depth. This study was designed to evaluate a stratified approach to ASCT, investigating if patients in CR/VGPR to induction may safely be assigned to delayed ASCT.
Aims: This single arm phase 2 clinical trial conducted at 13 UK sites aimed to determine the progression free survival (PFS) for patients who achieved ≥VGPR to induction therapy with no further treatment. Here we report the primary endpoint, PFS at 2 years in the patients not proceeding to ASCT, and the influence of MRD status on PFS.
Methods: NDMM patients eligible for ASCT received PAD (bortezomib 1.3mg/m2 IV or SC days 1, 4, 8, 11; doxorubicin 9mg/m^2 days 1-4, dexamethasone 40mg days 1-4 (and days 8-11 and 15-18 for cycle 1 only)) for 4-6 cycles. Those achieving <PR were off protocol; all others had PBSCH followed by restaging including MRD assessment on bone marrow using multi-parameter flow cytometry. Those in PR were stratified to ASCT (no maintenance) whereas those achieving ≥VGPR stopped treatment. Responses were assessed at 100 days post PBSCH (including MRD), and at monthly intervals for up to 2 years. High risk disease was defined by the presence of one or more adverse FISH lesions (t(4;14), t(14;16), t(14;20), del(17p13), +1q21).
Results: Between April 2011 and January 2014 153 patients were enrolled (median age 55, range 28-71 years), 139 (91%) received 4-6 cycles of PAD. The majority (88.2%) received SC bortezomib, 18 (11.8%) received at least 1 cycle IV. FISH data was available for 132 patients, 89 (67.4%) patients were standard and 43 (32.6%) adverse risk. 51 (33.6%) patients were ISS I, 67 (44.1%) ISS II and 34 (22.4%) ISS III. The overall response rate to PAD was 82.4% (≥VGPR: 41.2%). Responses were similar irrespective of ISS or genetic risk (standard: ≥VGPR 37.5%, PR 40.9%, adverse: ≥VGPR 53.5%, PR 34.9%). Post-PBSCH, 63 (41.2%) patients achieved ≥VGPR, and 44 (28.8%) patients achieved PR of whom 36 proceeded to ASCT. After a median follow-up of 45.4 months from registration, median overall PFS was 22.5m (95% CI: 18.1-25.3). For those who achieved ≥VGPR, median PFS from PBSCH was 8.9m (95% CI: 4.6-13.3) and 25.7m (95% CI: 13.7-37.6) for MRD+ (N=25) and MRD- (N=16) patients at D100 post-PBSCH respectively, 2y-PFS 28.0% (95% CI: 10.4-45.6) and 56.3% (95% CI: 32.0-80.6) respectively. PR patients proceeding to ASCT had a median PFS of 17.2m (95% CI: 14.2-20.2) and 23.1m (95% CI: 16.8-29.4) for those who were MRD+ (N=20) and MRD- (N=7) at D100 respectively, 2y-PFS 15.0% (95% CI: 0-30.7) and 42.9% (95% CI: 6.2-79.6) respectively.
Summary/Conclusions: This is the first study to report outcomes of patients stratified to ASCT by depth of response. The overall PFS for the study is shorter than other published trials, most likely due to the inferior outcome for MRD+ patients not proceeding to ASCT. The median PFS for ≥VGPR patients who are MRD- and stopped therapy was similar to that in PR patients achieving MRD- status post-ASCT. The PFS for ASCT was relatively short, reflecting selection of those only achieving PR. Response rate alone is not sufficient to identify patients who would benefit from ASCT and use of MRD to stratify treatment is now being investigated.

P670

PROPORTION AND COMPOSITION OF BONE MARROW LYMPHOCYTE POOL AT BASELINE CORRELATES WITH OUTCOME IN MM PATIENTS AFTER RVD AND ASCT

S. Luoma[1,2,*], S. Ilveskero[3], S. Rounioja[4], J. Valtola[5], T. Lundan[6], J. Lievonen[1], T.-T. Pelliniemi[4], K. Porkka[1,7], E. Jantunen[5], R. Silvennoinen[1,2,5]
[1]Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center, [2]University of Helsinki, [3]HUSLAB, Department of Clinical Chemistry and Hematology, Helsinki University Hospital, Helsinki, [4]Fimlab Laboratories Ltd, Tampere University Hospital, Tampere, [5]Department of Medicine, Kuopio University Hospital, Kuopio, [6]Department of Clinical Chemistry and TYKSLAB, Turku University Hospital, Turku, [7]Hematology Research Unit Helsinki, University of Helsinki, Helsinki, Finland

Background: In multiple myeloma (MM) the interactions between malignant plasma cells and the bone marrow (BM) microenvironment are important for treatment outcome. There is limited data on the effects of lenalidomide (LEN) on the BM immune profile and its therapeutic predictive value. The FMG-MM02 study (NCT01790737) was designed to explore the response to LEN, bortezomib and dexamethasone (RVD) induction, followed by a single autologous stem cell transplantation (ASCT) and LEN maintenance as a first-line therapy for MM patients (n=80). The primary endpoint was achievement of an immunophenotypic remission. Here we report the results of one of the secondary endpoints; composition of lymphocyte subsets at baseline and during LEN maintenance.
Aims: The aim of this study was to assess the proportion of different lymphocyte subsets at baseline and after ASCT and correlate lymphocyte composition with patient outcome.
Methods: Flow cytometry (FC) panel included antibodies against CD38, CD138, CD45, CD19, CD56, CD27, CD28, CD81, CD117, intracytoplasmic kappa and lambda. Sequential analyses (at baseline, after induction and at 3, 9 and 16 months after ASCT) were performed in 37/80 patients who achieved at least near complete remission (nCR) and/or minimal residual disease (MRD) negativity by FC. In addition to MRD the samples of these patients were analyzed for mature B-cells (CD19+/CD45++), B-cell progenitors (CD19+/CD81++/CD38+/CD45+), B-cell blasts (CD19+/CD81++/CD38+/CD45dim), NK/T-cells (CD45++/CD56+), T-cells (CD45++ lymphocytes other than B-cells and T/NK-cells) and CD38+ activated T-cells as calculated per total bone marrow nucleated cells (TNC). The results were compared between two different response cohorts: the good cohort (n=26) defined by persistent stringent complete remission/FC negativity, or PCR negativity (≤ 0.006%) and the control cohort (n=11), who only achieved nCR or had early relapse within one year of ASCT.
Results: At baseline, markers for disease burden, such as the percentage of myeloma cells in BM or paraprotein levels did not differ between the response cohorts. No differences were noted in R-ISS or ISS risk stratification either, but there were more IMWG high risk patients in the control cohort (p=0.048). The median percentage of total lymphocytes (15.4 *vs* 11.9; good *vs* control), T-cells (9.6 *vs* 7.8), CD19+ B-cells (1.6 *vs* 1.3), and CD38+ T-cells (0.9 *vs* 0.5) in BM were all higher in the good response cohort at baseline. In particular, the median proportion of mature B cells in BM was significantly higher in the best cohort at baseline (1.32 *vs* 0.91; p=0.02), after induction (0.27 *vs* 0.13; p=0.002) and 16 months after ASCT (1.73 *vs* 0.56; p=0.008) (*Figure)*.

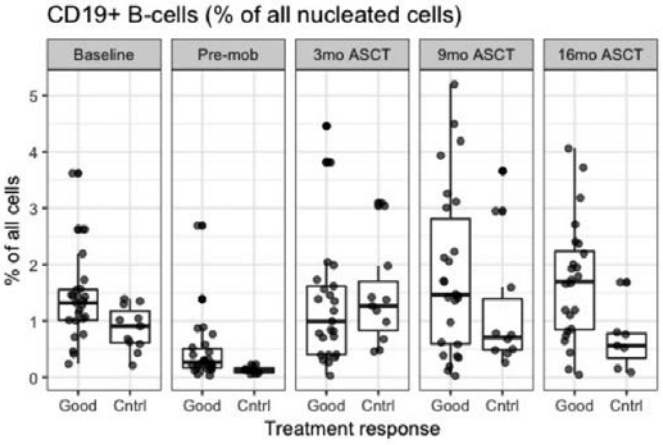

Figure 1.

Summary/Conclusions: Composition of the BM lymphocyte pool at treatment baseline may have an influence on treatment outcome in multiple myeloma. More detailed subtyping of the lymphocyte phenotypes is ongoing and may reveal potential predictive biomarkers for immunomodulatory drugs such as lenalidomide and checkpoint inhibitors.

P671

VALUE OF THE 18F-FDG PET-CT IN THE IDENTIFYING BONE INVOLVEMENT EITHER AT DIAGNOSIS OR DURING FOLLOW-UP OF PATIENTS AFFECTED BY MULTIPLE MYELOMA

S. Galimberti[1,*], W. Bertolami[1], P.A. Erba[2], D. Caramella[3], F. Caracciolo[1],

E. Benedetti[1], G. Buda[1], E. Orciuolo[1], N. Cecconi[1], G. Cervetti[1], M. Rousseau[1], L. Iovino[1], F. Mazziotta[1], M. Petrini[1]
[1]hematology, [2]Nuclear Medicine, [3]Radiology, Pisa, Italy

Background: Lytic lesions occur in the majority of patients with multiple myeloma (MM) and represent one of the criteria for starting therapy. In the past, whole-body X-ray (WBX) represented the method of choice for detecting skeleton abnormalities; today, magnetic resonance imaging (MRI), positron emission tomography (PET) and computed tomography (CT) have been adopted for their higher power in detecting extra-medullary localizations and their higher sensitivity. Nevertheless, which technique would be really the best one is still matter of debate.
Aims: Our single-center retrospective study was designed to compare PET-CT with other imaging techniques (WBX, vertebral column CT and MRI) at the diagnosis and during the follow-up of MM patients. Finally, we assessed a possible predictive/prognostic role of the PET-CT in terms of quality of response and survival.
Methods: We enrolled 160 patients with diagnosed symptomatic (N=149) or smoldering multiple myeloma (N=11) observed at the AOUP, Pisa, Italy, between January 1996 and December 2015. Eighty-three were male and 77 female; the median age was 70 years (range, 28-85), and half of them presented with low ISS risk score. Forty-five subjects were not eligible to high-dose therapy; 64% of them received bortezomib- and 23% melphalan-based regimens. Patients eligible to high-dose therapy received VAD, TAD or VTD and then one (88%) or two (12%) autologous transplants. At the relapse, lenalidomide (57%) or anthracyclines (40%) were administered.
Results: Overall, we compared 160 PET-CT, 233 WBX, 106 CT, and 85 MRI exams. At diagnosis, PET-CT allowed detecting skeletal involvement in 18% of cases negative by WBX, in 37% of those CT-negative, and in 10% of those MRI-negative. Sensitivity of PET-CT was superimposable to that of MRI (90%), and higher than that of WBX (60%) and CT (73%). Nevertheless, the specificity was lower for PET-CT and MRI (40%) in respect of CT (51%) and WBX (71%). Analogously to that observed at diagnosis, PET-CT during follow-up showed distinct advantages in terms of sensitivity compared to X-rays (83% *vs* 60%, respectively). In contrast, PET-CT sensitivity was comparable to that of CT and MRI. As at diagnosis, the specificity was higher for WBX (70%) than for CT, RM and PET-CT (40% for all of these). When PET-CT was correlated to the quality of response, it was significant only in the not transplanted cohort (>PR rate in PET-negative cases=67% *vs* 23% in the PET-positive group; p=0.016). Nevertheless, PET-CT positivity either at diagnosis or during follow-up did not impact on long-term OS and PFS.
Summary/Conclusions: Our study showed that PET-CT and MRI would represent the techniques of choice in the assessment of bone involvement in MM patients in view of their high and comparable sensitivity. Moreover, PET-CT gives the possibility of a "whole body" analysis in exchange for higher "biologic" cost.

P672

INITIAL PHASE 2 RESULTS OF IBRUTINIB COMBINED WITH BORTEZOMIB/DEXAMETHASONE IN PREVIOUSLY TREATED PATIENTS WITH MULTIPLE MYELOMA

R. Hájek[12,*], L. Pour [3], I. Špička[4], M. Özcan[5], V. Maisnar[6], M. Turgut[7], L. Kwei[8], Z. Salman[8], E. Bilotti[8], A. Oriol[9]

Background: Bruton's tyrosine kinase (BTK) is overexpressed in, and has been implicated in the growth and survival of multiple myeloma (MM) cells, providing a rationale for evaluating BTK inhibitors in MM (Yang *Cancer Res* 2015; Tai *Blood* 2012). Yang 2015 demonstrated that BTK overexpression (OE) contributes to blunted responses in MM cells when treated with widely used MM drugs (ie, bortezomib [BTZ], etoposide and doxorubicin). Increased activity of the ABC transporter efflux pump and expression of the ABCB1 transporter protein was seen in BTK OE cells, and subsequent inhibition led to a restoration of BTZ sensitivity in these cells. Ibrutinib (ibr), a first-in-class, once-daily oral inhibitor of BTK, is approved in the US and EU for the treatment of various B-cell malignancies. In the EU, regimens containing BTZ and corticosteroids are a standard of care in MM treatment. A previous study of ibr+carfilzomib±dexamethasone (dex) demonstrated an ORR of 58% in relapsed/refractory MM patients (pts) with a median of 3 prior therapies and 88% refractory to their most recent therapy (Chari ASH 2015), warranting further investigation of ibr with proteasome inhibitors.
Aims: To evaluate safety and efficacy of combination ibr+BTZ/dex in previously treated MM pts.
Methods: In this phase 2, open-label, multicenter, European study (PCYC-1139), eligible pts received 1-3 prior therapies and demonstrated disease progression on or following the most recent therapy. Prior BTZ use was permitted provided pts were sensitive (ie, no progression ≤60 days after having achieved minimal response or better). All pts provided informed consent. For cycles 1-8 (21-day cycles), pts received ibr 840mg once daily with BTZ 1.3mg/m^2 subcutaneously twice weekly (Days 1, 4, 8, 11) and dex 20mg on day of and after BTZ. For cycles 9-12 (42-day cycles), BTZ was dosed weekly (Days 1, 8, 22, 29). The primary endpoint was PFS with secondary endpoints including safety, ORR, PFS at landmark points, duration of response, and time to progression (TTP).
Results: As of November 21, 2016, 20 pts were enrolled (Table). Median age was 68.5 years (range, 49-86). Median number of prior therapies was 1, with 50% refractory to the most recent therapy and 70% previously exposed to BTZ. Gene expression profiling (GEP) in initial pts indicated high-risk GEP in 35% of pts. Virtual fluorescent *in situ* hybridization identified 40% of pts with high-risk cytogenetics. Median treatment duration was 2.1 months (range, 0.5-3.7). All pts experienced at least one treatment-emergent adverse event (AE) of any grade. The most common all-grade nonhematologic AEs occurring in >15% (>3 pts) were diarrhea (50%), upper respiratory tract infection (30%), and asthenia, peripheral edema, hypocalcemia and hypokalemia (20% each). The most common Grade ≥3 AEs occurring in ≥10% (>1 pt) were thrombocytopenia (25%), asthenia and pneumonia (15% each), and hyponatremia, abnormal hepatic function, infection, and bone pain (10% each). Three deaths were reported (sudden death in a pt with cardiac history, pneumonia, and myocardial infarction). With early follow-up, 19 pts are evaluable for response with an ORR of 47%, including MR or better in 68%. Updated data will be presented.

Table 1.

Characteristic	Patients (N=20)
Median age, y (range)	68.5 (49-86)
Median time from diagnosis, y (range)	3.1 (1.2, 10.9)
Male, n (%)	10 (50)
ECOG PS 0/1/2, n (%)	11/8/1 (55/40/5)
ISS stage at baseline, n (%)	
I/II/III	6/7/5 (30/35/25)
Disease status to last treatment, n (%)	
Relapsed	9 (45)
Relapsed and refractory*	10 (50)
Unknown	1 (5)
Median prior therapies, n (range)	1 (1-3)

Genomic Profile	
Gene Expression risk score, n	
Low/High	13/7
Molecular subtype, n	
CD1 (Cyclin-D1)	1
CD2 (Cyclin-D2)	5
HY (Hyperdiploidy)	4
LB (Low Bone-Disease)	4
MF (MAF-associated)	0
MS (MMSET)	2
PR (Proliferation)	4

ECOG PS, Eastern Cooperative Oncology Group performance status; FISH, fluorescent in situ hybridization; ISS, International Staging System. *Refractory defined as either no response or progression on or within 60 days of last treatment

Summary/Conclusions: The initial data indicate promising clinical potential for the combination of ibr+BTZ+dex. Treatment was generally well tolerated without any unexpected safety signals noted for the combination. The preliminary ORR of 47% after a minimum 2 treatment cycles is encouraging with further follow-up needed.

P673

PROGNOSTIC SIGNIFICANCE OF CLONAL CIRCULATING PLASMA CELLS BY MULTI-PARAMETRIC FLOW CYTOMETRY IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

S. Sidana[1,*], N. Tandon[1], A. Dispenzieri[1], M.A. Gertz[1], F.K. Buadi[1], M.Q. Lacy[1], D. Dingli[1], A.L. Fonder[1], S.R. Hayman[1], M.A. Hobbs[1], Y.L. Hwa[1], P. Kapoor[1], R.A. Kyle[1], N. Leung[1], R.S. Go[1], J.A. Lust[1], S.J. Russell[1], S.V. Rajkumar[1], S.K. Kumar[1], W.I. Gonsalves[1]
[1]Hematology, Mayo Clinic, Rochester, United States

Background: Presence of circulating plasma cells (cPCs) prior to autologous stem cell transplant (ASCT) is an adverse prognostic factor in patients with multiple myeloma (MM). Prognostic value of cPCs prior to ASCT in patients with light chain amyloidosis (AL) is not known.
Aims: The aim of our study was to evaluate if the presence of cPCs by multiparametric flow cytometry (MFC) prior to ASCT is prognostic in patients with AL.
Methods: We retrospectively analyzed 130 patients diagnosed from 2008–2015 with AL who had cPCs analyzed by MFC prior to ASCT, and categorized them as follows: a) Group 1: patients proceeding directly to ASCT without induction therapy and b) Group 2: patients who received induction therapy before ASCT.

Results: There were 78 patients in Group 1 and 52 patients in Group 2. Patients in Group 2 had higher baseline dFLC, bone marrow plasma cells (BMPC), Mayo stage and were more likely to have active MM compared to patients in Group 1. Table 1 lists baseline characteristics of the patients in Groups 1 and 2. Patients in Group 1 had higher rate of renal involvement. cPCs were detectable in 22% (n=28) of patients at the time of ASCT. More patients in Group 1 had detectable cPCs than in Group 2 (31% *vs* 8%; p=0.002), likely due to clearance of cPCs with treatment. Data on cPCs at diagnosis in the induction group was available in 14 patients, of whom 57% (n=8) had detectable cPCs *vs* 31% in the direct ASCT group (p=0.06). 6 of the 8 (75%) patients cleared cPCs with induction therapy. There were no significant differences in patients who had detectable and undetectable cPCs before transplant, including organ involvement, baseline dFLC, BMPC, and Mayo Stage (data not shown).

In Group 2, both progression free survival (PFS) (10.5 months *vs* 58 months, p <0.0001) and overall survival (OS) (16 months *vs* not reached, p <0.0001) were worse in patients who had detectable cPCs compared to those without cPCs (Figure 1). This difference was not seen in Group 1 (OS: not reached *vs* 98 months, p=0.96; PFS 43 *vs* 52 months, p=0.74). In multivariate analysis, adjusting for Mayo Stage and induction chemotherapy, there was a trend towards worse OS in patients with detectable cPCs (p=0.06).

Table 1.

	Induction Group (n=52)	Direct ASCT group (n=78)	P value
Median age (interquartile range [IQR])	60 years (55-67)	61 years (55-67)	0.6
Sex, males	65% (n=34)	64% (n=50)	0.88
Involved light chain (Lambda)	51% (n=26)	72% (n=54)	**0.04**
Median dFLC at diagnosis (IQR)	49 mg/dL (20-166)	13 mg/dL (5-53)	**<0.0001**
Median BMPC (IQR)	20% (10-49)	10% (5-10)	**<0.0001**
Cardiac involvement	49% (n=25)	47% (n=37)	0.86
Renal involvement	50% (n=25)	68% (n=52)	0.05
Liver involvement	8% (n=4)	4% (n=3)	0.3
Mayo Stage - 1	19% (n=8, N=43)	52% (n=40, N=77)	**0.002**
Mayo Stage - 2	49% (n=21)	29% (n=22)	
Mayo Stage - 3	19% (n=8)	7% (n=5)	
Mayo Stage - 4	14% (=6)	13% (n=10)	
Active Myeloma	48% (n=25)	4% (n=3)	**<0.0001**

Figure 1
Patients receiving induction chemotherapy before ASCT

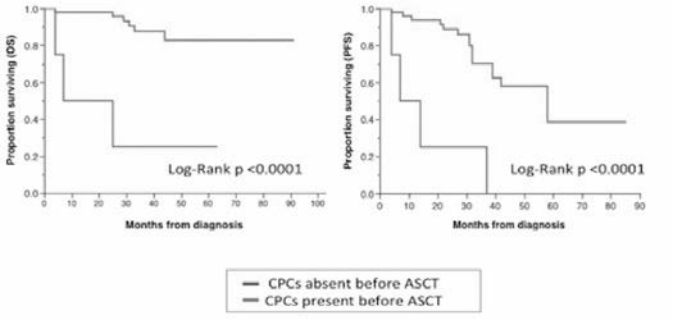

Figure 1.

Summary/Conclusions: cPCs are cleared after induction treatment in majority of AL patients. Patients who have detectable cPCs prior to proceeding to ASCT after induction have worse PFS and OS than patients without cPCs. On the other hand, presence of cPCs was not found be an adverse prognostic factor in patients proceeding directly to ASCT. This may be due otherwise excellent prognosis in this group, with absence of other high-risk features that are seen in patients who require induction. A limitation of our study is lack of data on cPCs at diagnosis in all patients who received induction therapy.

P674

RENAL IMPAIRMENT IN MYELOMA - PATIENT CHARACTERISTICS, TREATMENT MODALITIES, STEM CELL TRANSPLANT & OUTCOMES FROM THE AUSTRALIAN AND NEW ZEALAND MYELOMA REGISTRY

P.J. Ho[1,*], E. Moore[2], Z. McQuilten[2], K. Bergin[2], B. Augustson[3], H. Blacklock[4], N. Horvath[5], T. King[1], J. McNeil[2], P. Mollee[6], H. Quach[7], C. Reid[2], B. Rosengarten[8], P. Walker[9], E. Wood[2], A. Spencer[9]

[1]Institute of Haematology, Royal Prince Alfred Hospital, Sydney, [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, [3]Dept of Haematology, Sir Charles Gardiner Hospital, Perth, Australia, [4]Dept of Haematology, Middlemore Hospital, Auckland, New Zealand, [5]Dept of Haematology, Royal Adelaide Hospital, Adelaide, [6]Dept of Haematology, Princess Alexandra Hospital, Brisbane, [7]Dept of Haematology, St Vincent's Hospital, [8]Myeloma Foundation of Australia, [9]Dept of Haematology, The Alfred Hospital, Melbourne, Australia

Background: Renal impairment (RI) is a poor prognostic factor in multiple myeloma (MM). Analysis of disease characteristics, therapy & outcomes can improve treatment & prognosis.

Aims: To assess (1) characteristics of patients with RI at diagnosis - severity of RI, age, risk factors, high risk features, stage, disease manifestations & performance status, and (2) treatment including induction therapy & autologous stem cell transplant (ASCT) and outcomes.

Methods: Data from newly diagnosed MM patients enrolled in the Australian and New Zealand Myeloma Registry from 1 Feb 2013 to 31 Dec 2016 were analysed.

Results: Of 867 patients, 775 had eGFR available at diagnosis: 34% (267/775) had eGFR <60ml/min (22% at 30-60ml/min; 6% at 15-30ml/min; 6% at <15 ml/min). Mean age of patients with RI (<60 ml/min) was 72 *vs* 64 yrs without RI. Diabetes mellitus (DM), a major cause of chronic kidney disease (CKD), was more prevalent in patients with RI: 17% of patients with eGFR <30 ml/min compared with 8% >30ml/min. Patients with RI (<30ml/min) and DM had a similar response to first-line therapy compared to RI without DM (≥PR, 75% *vs* 82%, p=0.56), with no difference in OS (26 *vs* 37 mths, p=0.68) or PFS (24 mths, p=0.82). High risk features of FISH (del17p, t(4:14), t(14;16), amp1q21, del13q) & high LDH were more prevalent in RI (55% vs 46%, p=0.02), as was advanced stage (ISS III) (66% *vs* 12% p<0.001). Anemia was more prevalent in RI (44% *vs* 14 %, p<0.001), but bone lesions were less prevalent (52% *vs* 65% p=0.001). There was no difference in ECOG performance status. Most patients (87%) received Bortezomib-based therapy in first line (81% RI *vs* 91% no RI, p<0.001), with no difference with or without ASCT. Response rates (≥PR) were the same in patients with eGFR <60ml/min compared with normal renal function (84% *vs* 85%, p=0.87). PFS & OS decreased with reduction in eGFR (Fig 1). However, patients with eGFR<15ml/min had better OS & PFS compared with eGFR 15-30ml/min; dialysis in eGFR <15ml/min may be a factor. Using age 70 yrs as a common age limit for ASCT, we analysed the effect of ASCT in patients <70 yrs with & without RI. While a smaller proportion of RI patients received ASCT (21% *vs* 79%, p<0.07), it was performed at all levels of renal function including eGFR <15ml/min. In patients with eGFR <60ml/min, those who received ASCT had a longer PFS (HR 0.37, 95%CI 0.16-0.88, p=0.03) & OS (HR 0.28, 95%CI 0.08-1.01, p=0.05) compared with no ASCT. The improvement was also seen in severe RI (<30ml/min), with a longer PFS (HR 0.21, 95%CI 0.05-0.86, p=0.03) & OS (HR 0.10, 95%CI 0.01-0.82, p=0.03) with ASCT.

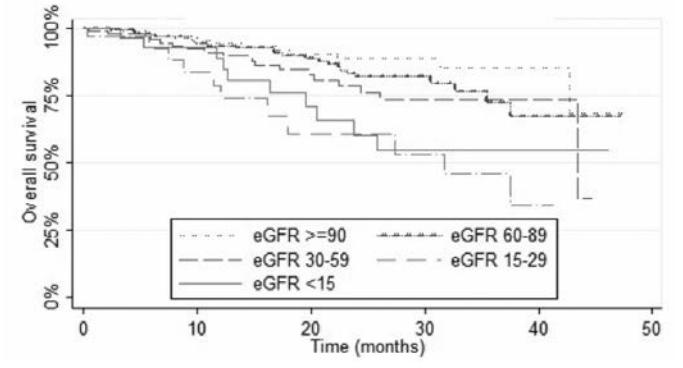

Figure 1.

Summary/Conclusions: RI occurred in one-third of newly diagnosed MM. DM, an underlying risk factor for CKD, was more common in RI patients, but not associated with a difference in outcome. Advanced stage & high risk features were more prevalent in RI patients, but bone disease was less common. RI patients had a shorter PFS and OS, overall correlating with eGFR. However patients with eGFR <15ml/min had a better OS than 15-30 ml/min, for which dialysis may be a factor. In transplant-eligible patients assessed by age <70 yrs, ASCT was performed in 21% of RI patients, at all levels of renal function. Patients with RI who underwent ASCT had a superior PFS and OS than those who did not have ASCT, including those with severe RI (eGFR <30ml/min), supporting the benefit of ASCT in MM patients with RI.

P675

VENETOCLAX AS TARGETED THERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA

S. Kumar[1,*], J.L. Kaufman[2], J. Mikhael[3], C. Gasparetto[4], R. Vij[5], B. Pegourie[6], L. Benboubker[7], T. Facon[8], P. Moreau[9], M. Amiot[9], S. Alzate[10], M. Dunbar[10], T. Xu[10], S. Agarwal[10], J. Leverson[10], J. Ross[10], P. Maciag[10], M. Verdugo[10], C. Touzeau[9]

[1]Mayo Clinic, Rochester, [2]Winship Cancer Institute of Emory University, Atlanta, [3]Mayo Clinic, Scottsdale, [4]Duke University, Hematologic Malignancies & Cellular Therapy, Durham, [5]Washington University School of Medicine, St. Louis, United States, [6]CHU Grenoble, Grenoble, [7]CHRU Tours, Tours, [8]CHRU Lille, Hopital Huriez, Lille, [9]CHU de Nantes, Hotel Dieu–HME, Nantes, France, [10]AbbVie Inc., North Chicago, United States

Background: Venetoclax (VEN), an orally available selective small-molecule

BCL-2 inhibitor, induces cell death in multiple myeloma (MM) cells, particularly those with the t(11;14) translocation.
Aims: The objectives of the study are to evaluate safety, PK, recommended phase two dose, and preliminary efficacy of VEN monotherapy in relapsed/refractory (R/R) MM.
Methods: Patients (pts) with relapsed/refractory (R/R) MM received VEN monotherapy in this phase 1 study. Daily VEN was given at 300–1200mg in dose escalation cohorts and 1200mg in the safety expansion. Pts with disease progression (PD) on VEN monotherapy could receive VEN plus dexamethasone and remain on study.
Results: As of 19Aug2016, 66 pts were enrolled. Median age was 63 years and 30 (46%) pts had t(11;14). Median number of prior therapies was 5 (range: 1–15); 46 (70%) pts were refractory to bortezomib, 20 (30%) to carfilzomib, 51 (77%) to lenalidomide, 35 (53%) to pomalidomide, and 52 (79%) were refractory to the last prior therapy. Median time on VEN monotherapy was 2.5 months (range: 0.2–23); 17 pts received VEN plus dexamethasone after PD for a median of 1.4 months (range: 0.1-13). Fifty-five (83%) pts discontinued, with 41 due to PD. Common adverse events (AEs) were nausea (47%), diarrhea (36%), vomiting (21%) and grade 3/4 hematologic toxicities [thrombocytopenia (32%), neutropenia (27%), anemia (23%), leukopenia (23%)]. Common serious AEs were pneumonia (8%), sepsis (5%), cough, hypotension, pain, and pyrexia (3% each). There were no events of TLS. Six deaths were reported due to PD, and 1 each due to lung disorder and brain hemorrhage following trauma. Overall response rate (ORR) for all pts on VEN monotherapy was 21% (14/66); 10 (15%) achieved very good partial response (VGPR) or better [2 stringent complete response (sCR), 3 CR, 5 VGPR]. For all pts, median time to progression (TTP) and duration of response (DoR) were 2.6 and 9.7 months, respectively. A clear difference in responses was seen among pts with t(11;14) *vs* without [ORR, 40% *vs* 6%; ≥VGPR, 27% *vs* 6%]. For pts with t(11;14), median TTP was 6.6 months [vs 1.9 months for pts without t(11;14)] and median DoR was 9.7 months. A high *BCL2:BCL2L1* (BCL-X_L) gene expression ratio was observed in 10/44 (23%) baseline tumor samples, enriched in pts with t(11;14) compared with non-t(11;14) (38% *vs* 5%) and associated with clinical response; 80% (8/10) of pts [all t(11;14)] with a high *BCL2:BCL2L1* ratio achieved ≥PR with a median TTP of 11.5 months. Among pts with t(11;14) who were refractory to the last therapy, ORR was 42% (11/26); for t(11;14) pts refractory to both bortezomib and lenalidomide, or who were refractory to bortezomib, carfilzomib, lenalidomide, and pomalidomide, ORR was 40% (8/20) and 50% (3/6), respectively. No difference was seen in ORR for t(11;14) pts with high-risk del(17p) *versus* those without the deletion [40% (2/5) *vs* 40% (10/25)].
Summary/Conclusions: VEN has an acceptable safety profile with promising single-agent anti-myeloma activity in pts with R/R MM positive for t(11;14) who failed multiple prior lines of therapy.

P676

AN OPEN-LABEL, PHASE 1B STUDY (MMY1001) OF DARATUMUMAB COMBINED WITH CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE (KRD) IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

S.Z. Usmani[1,*], A. Chari[2], S. Lonial[3], B. Weiss[4], R.L. Comenzo[5], K. Wu[6], N.Z. Khokhar[6], J. Wang[7], P. Doshi[6], A. Jakubowiak[8]
[1]Levine Cancer Institute/Carolinas HealthCare System, Charlotte, NC, [2]Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY, [3]Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, [4]Abramson Cancer Center and Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [5]Division of Hematology/Oncology, John C. Davis Myeloma and Amyloid Program, Tufts Medical Center, Boston, MA, [6]Janssen Research & Development, LLC, Spring House, PA, [7]Janssen Research & Development, LLC, Raritan, NJ, [8]University of Chicago Medical Center, Chicago, IL, United States

Background: The combination of daratumumab with standard of care regimens has demonstrated significantly prolonged progression-free survival (PFS), deeper responses, and a manageable safety profile *versus* standard of care alone in patients with relapsed or refractory MM.
Aims: To determine the tolerability and efficacy of daratumumab in combination with KRd in patients with newly diagnosed MM.
Methods: This open-label, phase 1b study enrolled patients with newly diagnosed MM regardless of transplantation eligibility. Patients received daratumumab 16mg/kg qw for Cycles 1-2, q2w for Cycles 3-6, and q4w thereafter, with all patients receiving the first dose split over 2 days. Carfilzomib was given on Days 1, 8, and 15 of each 28-day cycle (20mg/m^2 on Cycle 1 Day 1, 36 or 70mg/m^2 thereafter, based on tolerability of first dose) for up to 13 cycles or elective discontinuation for autologous stem cell transplantation (ASCT). Lenalidomide 25mg was administered on Days 1-21, and dexamethasone 20-40mg per week. The primary endpoint of the study was tolerability. Overall response rate (ORR; defined as partial response or better) was a major secondary endpoint.
Results: A total of 22 patients were enrolled in the study; median (range) patient age was 60 (34-74) years, and 95% had an ECOG score of ≤1. At a median (range) follow-up duration of 7.4 (4.0-9.3) months, the majority of patients remained on treatment and had received a median of 8 (1-10) treatment cycles. Six patients discontinued treatment, 1 due to an adverse event (AE; pulmonary embolism), 1 due to progressive disease, and 4 due to "other" (all ASCT). The dose of carfilzomib was increased to 70mg/m^2 in 19 patients by Cycle 1 Day 15. Serious treatment-emergent AEs (TEAEs) occurred in 46% of patients, 14% and 18% of which were at least possibly related to daratumumab or carfilzomib, respectively. Eighteen (82%) patients had a grade 3/4 TEAE, most commonly (>10%) lymphopenia (50%) and neutropenia (23%). One (5%) patient experienced a grade 3 cardiac TEAE (congestive heart failure) which resolved; the patient was able to resume study treatment at a reduced carfilzomib dose. There were no grade 5 TEAEs. Six (27%) patients had daratumumab-associated infusion-related reactions, and all were grade ≤2 in severity. ORR with daratumumab in combination with KRd was 100% among the 21 response-evaluable patients: 18 (86%) patients achieved a very good partial response or better and 1 patient (5%) achieved a complete response. Median duration of response has not been reached. With only 1 PFS event having occurred at the time of follow-up, 6-month PFS rate was 100%, and median PFS has not been reached.
Summary/Conclusions: Daratumumab in combination with KRd was well tolerated, with an overall safety profile consistent with previous reports for KRd. No additional toxicity occurred with the addition of daratumumab, and deep and durable responses were achieved. Preliminary results from this ongoing study support continued investigation of daratumumab plus KRd as a first-line treatment regimen for patients with newly diagnosed MM. Updated data based on longer follow-up will be presented.

P677

GENE EXPRESSION CLASSIFIER EMC92/SKY92 AND REVISED ISS ROBUSTLY IDENTIFY HIGH-RISK MULTIPLE MYELOMA IN ELDERLY PATIENTS OF THE HOVON-87/NMSG-18 STUDY

R. Kuiper[1,*], M.H. van Vliet[1], M. van Duin[2], A. Broijl[2], M.-D. Levin[3], L. de Best[1], E.H. van Beers[1], B. van der Holt[4], H. Visser[5], M. Hansson[6], A.W. van der Velden[7], B. Dumee[1], M. Vermeulen[2], J. Koenders[2], H.B. Beverloo[8], M. Stevens-Kroef[9], A. Waage[10], S. Zweegman[11], P. Sonneveld[2]
[1]Bioinformatics, SkylineDx, [2]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, [3]Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [4]Department of Hematology, [5]Erasmus MC Cancer Institute-Clinical Trial Center, HOVON Data Center, Rotterdam, Netherlands, [6]Division of Hematology and Transfusion Medicine, Skåne University Hospital, Lund, Sweden, [7]Department of Internal Medicine, Martini Hospital, Groningen, [8]Department of Clinical Genetics, Erasmus MC, Rotterdam, [9]Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, [10]Norwegian University of Science and Technology, Trondheim, Norway, [11]Department of Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Multiple myeloma (MM) affects mostly elderly people with a median age of 69 years at diagnosis, with 35-40% of patients older than 75. Overall survival (OS) is variable: of patients aged 66-79, 9% survive less than 3 months and 23% survive longer than 10 years.
Recently the revised ISS (rISS) has been proposed as a prognostic marker that incorporates ISS, FISH and LDH. Another marker, the SKY92 prognostic gene classifier (published as the EMC92 classifier) was developed in younger, transplant eligible multiple myeloma (MM) patients who were included in the HOVON-65/GMMG-HD4 trial. The SKY92 classifier was thoroughly validated in eight independent cohorts, at the time of its initial publication, and since.
Aims: Here, we validated the SKY92 gene expression classifier and rISS in elderly, non-transplant eligible patients included in the HOVON-87/NMSG-18 trial (Zweegman *et al.* Blood 2016;127(9):1109-1116).
Methods: In this trial, melphalan, prednisone, thalidomide (MPT) plus thalidomide maintenance was compared with melphalan, prednisone, lenalidomide (MPR) plus lenalidomide maintenance. The MMprofiler™ CE IVD assay was used to obtain SKY92 scores, classifying a patient as high-risk or standard-risk. In addition, the international staging system, LDH, FISH and rISS were analyzed.
Results: The 178 patients in the analysis for which enough bone marrow was available to perform GEP, had a median age of 73 years. At the time of data analysis, the median follow up was 34 months. The SKY92 classifier identified 25 of 178 patients as high-risk (14%). The median OS for the 25 patients classified as SKY92 high-risk was shorter than the median OS of standard-risk patients: SKY92 high-risk 21 months *versus* SKY92 standard-risk 53 months (hazard ratio (HR)=3.0, 95% confidence interval (CI)=1.7-5.3; p <.001; Figure 1a). The proportion of patients with stage rISS-III was 8% which is comparable to the 10% identified in the initial report of the rISS. Interestingly, the proportion of SKY92 high-risk patients is larger (14%), whereas the median OS associated with these patients is shorter (21 *vs* 25 months). The SKY92 classifier performed better compared to the rISS as high-risk marker for OS. The 2-year OS rate was 48% in the SKY92 high-risk patients *versus* 58% for rISS-III. (Figure 1). The 2-year progression free survival (PFS) rate was similar for SKY92 high-risk and rISS-III (16% and 17%, respectively). In the multivariate analysis, SKY92, rISS and deletion of 13q were independently associated with OS. Inde-

pendent association with PFS was found for SKY92, rISS, deletion of 13q and t(11;14) (Table 1). A bidirectional stepwise selection procedure was applied excluding covariates with the highest p-values until only significant covariates remain. Initially included covariates were SKY92, r-ISS, gain(1q), del(17p), del(13q), t(4;14), t(11;14), LDH and age. ISS could not be included as it was highly correlated with other covariates (i.e. co-linear); t(14;16) was excluded due to the minimal number of present instances. HR: hazard ratios relative to the lowest risk category with 95% confidence intervals (CI), p: likelihood ratio p-value indicating the association of each covariate with OS.

Table 1. Multivariate survival analysis in the HO87/NM18 trial.

		High-risk	Low-risk	HR [95%CI]	p
SKY92		17	122	2.9 [1.4-5.9]	$8.6x10^{-3}$
rISS	I	20	119	1.0	$7.8x10^{-3}$
	II	107	32	1.7 [0.67-4.4]	
	III	12	127	5.5 [1.8-17.0]	
del(13q)		67	72	1.9 [1.1-3.4]	$2.4x10^{-2}$
n = 139; number of events = 53; 4 degrees of freedom					$2.5x10^{-5}$

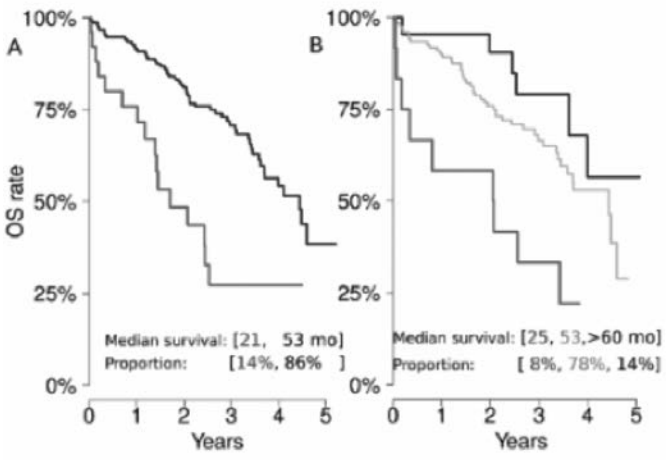

Figure 1. Survival curves for A) the SKY92 classifier and B) the revised ISS. In blue the lowest risk patients, in red the highest risk patients and orange indicating intermediate risk.

Figure 1.

Summary/Conclusions: Here, we compared the SKY92 classifier with revised ISS staging and FISH. These data validate the SKY92 classifier as a robust marker to identify high-risk patients in non-transplant eligible MM patients. In these IMiD treated patients, the SKY92, the revised ISS, and FISH markers such as deletion of 13q retain independent prognostic value.

P678

MULTIPLE MYELOMA AND COMORBIDITY: A POPULATION-BASED STUDY

I.S. Sverrisdottir[1,2,*], S. Rögnvaldsson[2], S. H. Lund[2], I. Turesson[3], M. Hultcrantz[4], M. Björkholm[5], O. Landgren[4], S.Y. Kristinsson[2]
[1]Internal Medicine, Landspitali, [2]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [3]University Hospital Malmö, Malmö, Sweden, [4]Division of Hematology, Oncology, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, United States, [5]Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

Background: The number of multiple myeloma patients has grown with aging populations, and with increasing age the number of comorbidities increases as well. Clinically, it is well known that comorbidity in multiple myeloma patients decreases performance status, increases risk of therapy-related complications and may lead to life-threatening conditions. Currently, the literature on comorbidity in multiple myeloma is very limited and based on small case series. Clinical trials rarely include elderly, frail patients due to eligibility criteria. Population-based studies provide valuable information on survival outcomes in relation to presence/absence of comorbidities in newly diagnosed real-life multiple myeloma patients in the general population.
Aims: To evaluate the prevalence of comorbidities and to study the impact of comorbidities on survival among patients with newly diagnosed multiple myeloma.
Methods: All newly diagnosed patients with multiple myeloma from January 1st 1990 to December 31st 2013 in Sweden were included in the study. Using the Swedish Patient Registry, all discharge diagnosis and discharge listings were gathered from each patient from January 1st 1985. Comorbid conditions were defined as chronic illnesses which demand life-long treatment or follow-up. Only those diagnoses made prior to multiple myeloma were used. Using ICD 8, 9 and 10 codes, comorbid diseases were identified. Kaplan-Meier curves were used to estimate survival. Risk of death was compared among multiple myeloma patients with a comorbid condition to those without a comorbidity, using Cox's proportional hazards regression (adjusting for age, gender, year of diagnosis, and other comorbid conditions).
Results: A total of 13,718 patients with multiple myeloma were included in the study and 21 groups of comorbidities were identified. The most common diseases were cancer, hypertension, heart failure, ischemic heart disease and atrial fibrillation. Among all patients, 55% had no prior history of comorbidity, 23% had one comorbidity, 12% had two comorbidities, and 10% had three or more comorbid conditions. Survival was negatively influenced by the number of comorbidities (Figure 1). The risk of death was significantly increased in patients with atrial fibrillation (HR=1.08; 95% CI 1.00-1.16), heart failure (HR=1.50; 95% CI 1.40-1.61), stroke (HR=1.20; 95% CI 1.11-1.30), psychological disease (HR=1.27; 95% CI 1.16-1.39), chronic lung disease (HR=1.22; 95% CI 1.12-1.32), diabetes (HR=1.14; 95% CI 1.04-1.36), peripheral vascular disease (HR=1.26; 95% CI 1.12-1.42), cancer (HR=1.10; 95% CI 1.04-1.16), dementia (HR=1.65; 95% CI 1.38-1.99), paralysis (HR=1.44; 95% CI 1.15-1.80), inflammatory bowel disease (HR=1.38; 95% CI 1.08-1.74), end stage renal disease (HR=1.57; 95% CI 1.03-2.04), and cirrhosis (HR=1.64; 95% CI 1.10-2.43).

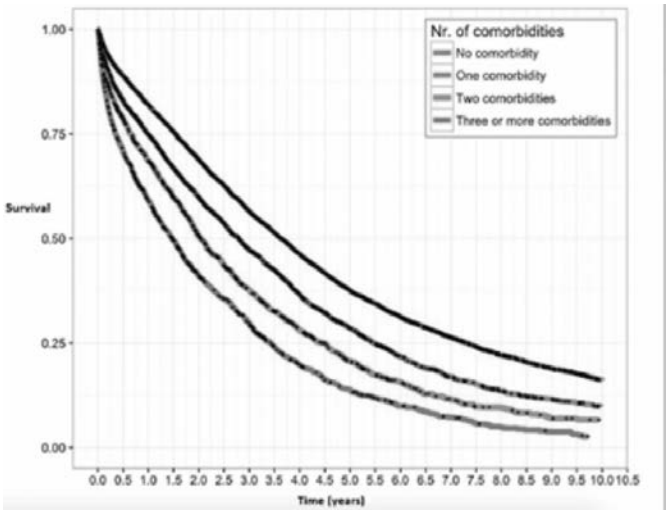

Figure 1.

Summary/Conclusions: In this large, population-based study including almost 14,000 patients, we have shown that comorbidities are common among newly diagnosed multiple myeloma patients and that comorbidities are associated with an inferior survival. Importantly, the number of comorbidities showed a dose-response relationship with inferior overall survival. For example, the median overall survival for patients with 3 or more comorbidities was reduced by more than 50% compared to patients without comorbidities. The importance of comorbidities should be taken into account when evaluating patients and deciding on treatment strategies for individuals with multiple myeloma.

DETECTION OF NEW EMERGING CLONES DURING TREATMENT BY NGS ALLOWS A BETTER RISK PREDICTION ON MULTIPLE MYELOMA PATIENTS

B. Sanchez-Vega[1,*], R. Mateos[1], I. Cuenca[1], N. Puig[2], S. Barrio[1], Y. Ruiz-Heredia[1], X. Aguirre[3], R. Ayala[1], L. Rosiñol[4], J. Blade[4], M.-V. Mateos[2], R. Garcia-Sanz[2], J. San Miguel[3], J.-J. Lahuerta[1], J. Martinez-Lopez[1]
[1]Hematología Traslacional, Hospital 12 de Octubre, Madrid, [2]Hospital Universitario de Salamanca, Instituto de Investigacion Biomedica de Salamanca (IBSAL), Centro de Investigación del Cancer (IBMCC CSIC-USAL), Salamanca, [3]Clinica Universidad de Navarra, Centro de Investigacion Medica Aplicada, Instituto de Investigación Sanitaria de Navarra, Pamplona, [4]Hospital Clinic, Barcelona, Spain

Background: Multiple myeloma (MM) is a genetically complex disease, characterized by the presence of multiple clones with differing degrees of drug sensitivity at the time of diagnosis. Consequently, therapeutic response of MM patients is unpredictable and extremely variable, and although the treatments introduced over the last decade have significantly improved the outcome of these patients, most patients eventually relapse. Deep sequencing methods have contributed to increase the knowledge about the clonal heterogeneity of the disease and helped to stablish the three evolution patterns at relapse: linear and branching clonal evolution, and no clonal changes.
Aims: To analyze the diversity and relative dominance of different clones and their evolution throughout the course of disease by NGS of the immunoglobulin repertoire in MM patients. To evaluate if the presence of different clones is associated with increased risk.
Methods: Immunoglobulin repertoire was analyzed by NGS in bone marrow samples from 180 MM patients included in three GEM clinical trials (NCT00461747, NCT00443235 and NCT01237249). The two first clinical trials involve patients younger than 65 years old, and were analyzed with ClonoSeq methodology, the later one involve patients older than 65 years old, and were analyzed with a local NGS method recently validated (Martinez-López et al, Laukemia 2017). A clonotype was identified when at least 400 identical sequencing reads were obtained, or it is present at a frequency of >1%.
Results: Of the 180 MM patients studied, 57 (32%) shows the presence of more than one clone throughout the clinical the course of the disease. The identification of new evolving clones was only possible in the GEM10 clinical trial with the Local NGS method; in this clinical essay, 6% (4/71) of patients shows the development of different clones during treatment. We show that the frequency of the predominant clone at diagnosis of these four patients decreased with treatment, but the frequency of the new ones increased and the patients progressed. When more than one clone is present at diagnosis, the relative dominance of the clones varies throughout the course of disease in an independent manner. There were no differences in median MRD values between patients with one clone or more than one clone (0.0082% and 0.0055% respectively). The presence of more than one clone was not associated with high-risk cytogenetics. The presence of more than one clone at diagnosis does not condition the prognosis in any of the patients and treatments analyzed. Median PFS was 38 and 58 months for patients with one clone or more one clone, respectively (HR=1.136, p= 0.563). Median OS was not reached for patients with one clone, and was 81 months for patients with more than one clone (HR=1.43, p=0.28).
Summary/Conclusions: The analysis of the IG repertoire by the local NGS method during treatment is able to identify and quantify new emerging clones during the treatment that were not detectable at diagnosis. The new clones contributed to increase the MRD levels in the follow-up samples.The presence of of different clones at diagnosis is not associated with higher risk of progression, high risk cytogenetics or higher MRD values.

P680

FINAL RESULTS OF PHASE (PH) 1/2 STUDY OF CARFILZOMIB, POMALIDOMIDE, AND DEXAMETHASONE (KPD) IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): A MULTI-CENTER MMRC STUDY

A.J. Jakubowiak[1,*], C.A. Rosenbaum[1], L. Stephens[1], V. Kukreti[2], C. Cole[3], T. Zimmerman[1], D. Reece[2], J. Berdeja[4], E. Severson[1], B. Wolfe[1], S. Major[1], K. McDonnell[1], J. Nam[1], A. Turowski[1], K. Griffith[3], J. Zonder[5]
[1]University of Chicago, Chicago, IL, United States, [2]University Health Network, Toronto, Canada, [3]University of Michigan, Ann Arbor, MI, [4]Sarah Cannon Research Institute, Nashville, TN, [5]Karmanos Cancer Center, Detroit, MI, United States

Background: In the era of increased use of 1st-line and maintenance lenalidomide (LEN), there is growing need for effective ≥2nd-line therapies (tx) for LEN-refractory pts. The combination of carfilzomib (CFZ), pomalidomide (POM), and dexamethasone (DEX) has shown promising activity in advanced RRMM, including for pts refractory to LEN (Shah *et al. Blood*. 2015).
Aims: In this Ph 1/2 study, KPd was evaluated in RRMM, with a focus on pts who are LEN-refractory but proteasome inhibitor (PI)-naïve/sensitive.
Methods: LEN-refractory disease was required for 2nd-line KPd and LEN-refractory/exposure for ≥3rd-line. Ph 1 dose escalation to determine maximum tolerated dose (MTD) followed the TITE-CRM design with 40 pts receiving 3–4mg POM PO (days [d] 1–21), 20–36mg/m^2 CFZ (IV d1, 2, 8, 9, 15, 16 in cycles [C] 1–8, and d1, 2, 15, 16 in C9+), and 40/20mg DEX PO weekly (C1–4/5–8; for all dose levels [DLs]) in 28-day cycles. CFZ was started at 20mg/m^2 for d1, 2 of C1 for all DLs. Per design, 30 PI-naïve/sensitive pts were to be enrolled at MTD across Ph 1/2, with partial response (PR) rate after C4 as 1º efficacy endpoint.
Results: As of 12/1/16, 65 pts have been enrolled, with efficacy and safety data available for 64 pts: 4 at DL1 (20mg/m^2 CFZ, 3mg POM), 29 at DL2 (20mg/m^2 CFZ, 4mg POM), 32 at DL3 (20/27mg/m^2 CFZ, 4mg POM), 0 at DL4 (20/36mg/m^2 CFZ, 4mg POM). Median age was 63 y, median time from diagnosis 5.1 y, median prior tx lines 2, and 94% had refractory disease. Cytogenetic data were available for 59 pts; 33% were high risk per IMWG. There were 9 dose-limiting toxicities, all asymptomatic cytopenias: 8 pts with grade (G) 3 neutropenia and 1 with G4 thrombocytopenia. The MTD was established at DL3. In 64 pts, G3/4 hematologic toxicities included neutropenia (25%) and lymphopenia (14%), and non-hematologic toxicities (all grades) included fatigue (51%), dyspnea (42%), and gastrointestinal (45%). PRs were rapid with a ≥PR rate of 63% after 1 cycle and 77% after 4 cycles. After a median of 20.9 cycles (range, 1–49), ≥minimal response was 95%, ≥PR 84%, ≥very good PR 52%, and ≥near complete response (nCR) 20%. In the 1º population (N=55, 51 LEN-refractory, 28 progressing on LEN maintenance), ≥PR was 84% with 30 treated at MTD. After median follow-up of 21 (1–49) mo, median progression-free survival (PFS) for all 64 pts enrolled was 16.8 mo and 2-y overall survival (OS) was 76.8% with 20 pts remaining on treatment. For standard-risk (n=38) *vs* high-risk pts (n=21), ≥PR was 89% *vs* 81%, ≥nCR was 24% *vs* 10%, median PFS was 22.3 *vs* 10.6 mo, and 2-y OS was 90.8% *vs* 56.0%.
Summary/Conclusions: KPd is well tolerated and highly active (≥PR 84%) with encouraging PFS (median 16.8 mo) in an RRMM pt population that was mostly LEN-refractory and PI-naïve/sensitive. The results support planned evaluation of KPd with daratumumab in RRMM, particularly for high-risk pts.

P681

PANOBINOSTAT INDUCES CD38 UPREGULATION AND AUGMENTS THE ANTI-MYELOMA EFFICACY OF DARATUMUMAB

E. Garcia-Guerrero[1,*], T. Gogishvili[1], S. Danhof[1], M. Schreder[1], C. Pallaud[2], J.A. Pérez-Simón[3], H. Einsele[1], M. Hudecek[1]
[1]Universitätsklinikum Würzburg, Würzburg, Germany, [2]Novartis Pharmaceuticals, Basel, Switzerland, [3]IBIS/Hospital Universitario Virgen del Rocío, Seville, Spain

Background: Immunotherapy with the anti-CD38 monoclonal antibody (mAb) daratumumab is increasingly being utilized in myeloma patients with relapsed/refractory (R/R) disease after prior treatment with immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs). However, the efficacy of daratumumab is limited by low CD38 expression on myeloma cells. Here, we investigate the use of the histone deacetylase inhibitor (HDACi) panobinostat to modulate target antigen expression on myeloma in favor of potent mAb-mediated recognition and destruction. We show that panobinostat augments CD38 expression specifically on myeloma cells and demonstrate powerful synergy with anti-CD38 mAb daratumumab.
Aims: Determine the impact of panobinostat on upregulation of CD38 expression on myeloma cells in order to enhance the efficacy of daratumumab.
Methods: Myeloma cells were treated with titrated doses of panobinostat (0, 10, 25 nM) and expression of CD38 and a panel of additional target molecules including SLAMF7, as well as accessory ligands analyzed by flow cytometry at 24, 48 and 72 hours. Antibody-dependent cellular cytotoxicity (ADCC) against panobinostat treated and untreated myeloma cells was analyzed at 4 and 20 hours after addition of PBMC at an effector to target ratio of 25:1 in the presence of daratumumab or an isotype control antibody.
Results: We treated primary myeloma (n=12 patients) with panobinostat (10 *vs* 25 nM) and observed a uniform increase in CD38 expression in each case by flow cytometry. Upregulation of CD38 was already detectable after 24 hours, peaked after 48 hours of exposure to panobinostat and was higher at the 25 nM compared to the 10 nM dose. At 48 hours, the mean fluorescence intensity (MFI) for CD38 expression was 4 (10nM) and 6-fold (25 nM) higher in panobinostat-treated compared to untreated myeloma ($p<0.01$). The increase in CD38 was equal in patients with previously untreated (n=5) and R/R myeloma (n=7); and could be confirmed in a panel of myeloma cell lines, including MM1.S and OPM-2. The panobinostat-induced upregulation of CD38 was rapidly reversible after drug withdrawal. Further, the increase in CD38 expression after panobinostat treatment was specific for myeloma and neither observed this phenomenon in a panel of leukemia and lymphoma cell lines, nor on primary CD8+ and CD4+ T cells that we isolated from peripheral blood of several donors

(n=3). Interestingly, expression of SLAMF7 was not increased after panobinostat treatment at all tested concentrations and time points in both cell lines and primary myeloma. Next, we were interested in determining whether the increase in CD38 expression enabled superior antimyeloma activity of the anti-CD38 mAb daratumumab. Thus, we treated primary myeloma cells from patients (n=4) with panobinostat for 48 hours at 10 nM, as this is the serum level achievable with currently approved dosing regimens. We observed a significant increase in ADCC against panobinostat-treated compared to untreated myeloma in all patients. On average, 78% of panobinostat-treated primary myeloma cells were eliminated by daratumumab within the 4-hour ADCC assay, whereas only 51% myeloma cells were eliminated without panobinostat treatment ($p<0.01$). The synergistic anti-myeloma efficacy of panobinostat and daratumumab was confirmed with a panel of myeloma cell lines.

Summary/Conclusions: Our data demonstrate that the HDACi panobinostat induces upregulation of CD38 on myeloma and a subsequent dramatic increase of daratumumab-mediated ADCC. These data suggest that panobinostat could be used synergistically with daratumumab in a clinical setting to increase response rates and extend duration of responses to daratumumab.

P682

BCL2 EXPRESSION IS A POTENTIAL PREDICTIVE BIOMARKER OF RESPONSE TO VENETOCLAX IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

J. Ross[1,*], B. Chyla[1], R. Goswami[1], L. Roberts-Rapp[1], Y. Sun[1], Y. Jiang[2], E. Punnoose[2], M. Verdugo[1], A. Bhathena[1], P. Maciag[1]
[1]AbbVie, Inc., North Chicago, [2]Genentech Inc., South San Francisco, United States

Background: The anti-apoptotic proteins BCL-2 and MCL-1 have been shown to promote multiple myeloma (MM) cell survival. Venetoclax (VEN) is a potent, selective, and orally bioavailable small-molecule inhibitor of BCL-2. Bortezomib (BTZ) is a proteasome inhibitor that can inhibit MCL-1 activity by increasing the MCL-1 antagonist, NOXA.
Aims: Results presented herein describe correlative biomarker analyses in the ongoing phase 1b study of VEN in combination with BTZ and dexamethasone in patients with relapsed/refractory (R/R) MM (NCT01794507).
Methods: As of 19 Aug 2016, 66 patients were enrolled on study. Baseline bone marrow aspirate samples were available from 52 patients, of which 45 were evaluable for BCL-2 family gene expression by droplet digital PCR in CD138-selected tumor cells. Correlation between *BCL2* (BCL-2), *BCL2L1* (BCL-XL) and *MCL1* (MCL-1) mRNA expression (log2-transformed copies/ul normalized to housekeeping gene) and preliminary efficacy [overall response rate (ORR), time to disease progression (TTP) and duration of response (DoR)] were examined by Log-rank and Wilcoxon tests for binary biomarkers, and by risk ratio from Cox proportional hazard model for continuous biomarkers.

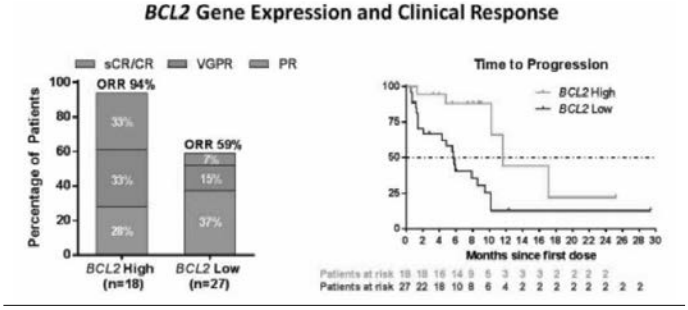

Figure 1.

Results: The ORR was 68% (44/65) for all evaluable patients and 89% (31/35) in patients who had 1-3 prior therapies (31/35). A broad range of *BCL2, BCL2L1* and *MCL1* expression was observed, however higher *BCL2* levels were detected in patients who achieved a partial response (PR) or better (median: 3.01 *vs* 0.87, $p<0.01$). Additionally, higher *BCL2* levels were observed in patients who had 1–3 prior lines of therapy compared to 4 or more lines of therapy (median: 3.03 *vs* 0.94, $p<0.01$). In contrast, no association was observed between *BCL2L1* or *MCL1* gene expression and response or number of prior therapies. Bootstrapping and aggregating thresholds from trees was used to estimate a threshold value for *BCL2* expression that would provide optimum selection of patients likely to have a response. Overall, seventeen of 18 patients with high *BCL2* expression *(≥3.0)* achieved at least a PR (ORR 94%), with 12 patients (66%) achieving VGPR or better (**Figure 1**). Sixteen of 27 patients with low *BCL2* expression achieved at least a PR (ORR 59%), with 6 patients (22%) achieving a VGPR or better. Median TTP (11.6 *vs* 5.7 months) and DoR (10.2 *vs* 7 months) were longer for patients with high *versus* low *BCL2* expression. Responses in high *BCL2* expressors were independent of cytogenetic status as determined by interphase FISH analysis, including t(11;14), t(4;14), del(13q) and del(17p).

Summary/Conclusions: Targeting BCL-2 and MCL-1 with the combination of VEN, BTZ and dexamethasone provides a unique approach for MM treatment. Efficacy results in tumors expressing high *BCL2* levels, including 94% ORR, provide supportive evidence for the evaluation of this combination regimen in the ongoing phase 3 study (NCT02755597) in R/R MM.

P683

THE IMPACT OF THE INTRODUCTION OF BORTEZOMIB ON DIALYSIS INDEPENDENCE IN MULTIPLE MYELOMA PATIENTS WITH RENAL FAILURE: A NATIONWIDE DUTCH POPULATION-BASED STUDY

B. Oortgiesen[1,*], R. Azad[1], M. Hemmelder[2], R. Kibbelaar[3], N. Veeger[4], J. de Vries[5], E. van Roon[16], M. Hoogendoorn[5]
[1]Department of Clinical Pharmacy & Pharmacology, [2]Department of Nephrology, Medical Centre Leeuwarden, [3]Department of Pathology, Pathology Friesland, [4]Department of Epidemiology, [5]Department of Hematology, Medical Centre Leeuwarden, Leeuwarden, [6]Department of Pharmacy, University of Groningen, Groningen, Netherlands

Background: Renal insufficiency is common at presentation in patients with multiple myeloma (MM) and associated with a poor survival. Approximately 10% of the patients require dialysis. Studies have shown that the novel agent bortezomib has a positive effect on recovery of renal function in MM patients with renal insufficiency.
Aims: The aim of this study is to determine the effect of the revised guideline, including the introduction of bortezomib as first line treatment in MM patients with dialysis dependence, on renal function recovery.
Methods: All patients on renal replacement therapy (RRT) in the Netherlands are registered in the Dutch registry Renine. Data on age, gender, start date of RRT, type and switches of RRT or hospitals, primary renal diagnosis, date of death and cause of death are collected. In this nationwide population-based study, we selected all patients with MM registered in Renine between January 2002 and January 2016. No information regarding therapy of MM is provided in Renine. In March 2010, bortezomib was advised as first-line treatment in patients suffering from MM with renal impairment in the Dutch guidelines. Therefore, we divided our cohort in two periods: before the bortezomib guideline (January 1, 2002 till March 29, 2010) and after introduction of the bortezomib guideline (March 29, 2010 till January 1, 2016). Kaplan-Meier and Cox proportional hazards modelling were used to identify significant indicators for dialysis independency.
Results: A total of 700 patients were included in the study (422 patients pre-bortezomib and 278 after bortezomib introduction). In the period after the introduction of bortezomib 15% of patients became dialysis independent compared to 8% in the pre-bortezomib period ($HR_{adj.}$=2.1 (95% CI 1.3–3.3), Fig. 1). In addition, patients who started dialysis in the period after bortezomib was introduced became dialysis independent more rapidly than in the pre-bortezomib period (1.2 compared to 1.7 years; $p < 0.001$). Age < 75 years (vs. ≥ 75 years) and light chain deposition disease (LCDD) as the primary renal disease (vs. amyloidosis) were significantly associated with achieving dialysis independence ($HR_{adj.}$=2.1 (95% CI 1.0–4.2) and $HR_{adj.}$=5.7 (95% CI 2.5–13.2), respectively).

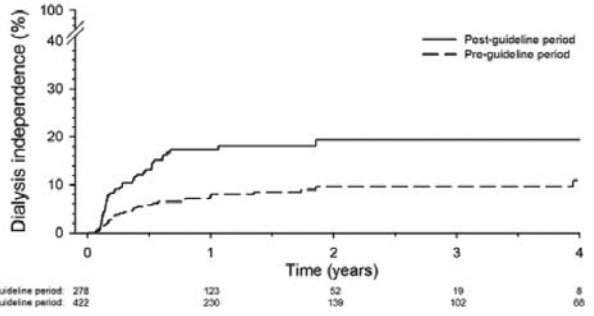

Figure 1.

Summary/Conclusions: In this nationwide population-based study, covering all patients with MM and concomitant renal failure, almost a two-fold increase of patients becoming dialysis independent occurred in the period after the introduction of bortezomib compared to the pre-bortezomib period. This was even more prominent when age was < 75 years and LCDD was the primary renal disease.

P684

TREATMENT WITH POMALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH MULTIPLE MYELOMA AND LIGHT CHAIN (AL) AMYLOIDOSIS

P. Milani[1,*], M. Basset[1], F. Russo[1], M. Bozzola[1], A. Foli[1], G. Palladini[1], G. Merlini[1]

[1]Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy

Background: The immunomodulatory agent pomalidomide is active in patients with relapsed/refractory multiple myeloma, including those who failed prior lenalidomide and bortezomib. Phase II clinical trials showed that pomalidomide is also effective in primary AL amyloidosis. After this drug was marketed for multiple myeloma (in Italy since September 2015), it became routinely accessible also to patients with myeloma-associated AL amyloidosis, a particularly fragile population.
Aims: Aim of this study is to report the efficacy of pomalidomide and dexamethasone in patients with multiple myeloma-associated AL amyloidosis.
Methods: The databases of the Pavia Amyloid Research and Treatment Center was searched for patients with a diagnosis of multiple myeloma and AL amyloidosis treated with pomalidomide and dexamethasone (PDex). The patients received 28-day cycles of pomalidomide (4mg from day 1 to 21) and dexamethasone (20/40mg weekly). All patients gave written informed consent for their clinical data to be used for research purposes, in accordance with the Declaration of Helsinki. Thirty patients were treated to date. Hematologic and organ response were assessed according to the International Society of Amyloidosis criteria.
Results: Median age was 65 years (range: 34-85 years) and 22 (73%) patients were man. Heart involvement was present in 13 patients (43%) and kidney involvement in 18 (60%). Four (13%) patients were in Mayo Stage I, 17 (57%) in stage II and 9 (30%) in stage III. Fifteen (50%) subject were in renal stage I, 8 (27%) and 3 (23%) were in renal stage II and III respectively and 5 (16%) patients were on dialysis at the time of PDex initiation. Median bone marrow plasma cell infiltrate was 20% (range: 12-90%). Twenty-three (76%) patients were refractory to all previous lines of therapy. Median time from diagnosis to treatment initiation was 71 months [interquartile range (IQR): 25-120 months]. Adverse events were observed in 5 (17%) of subjects: skin rash and confusion in one patient each and mild increase in serum creatinine in 3 (10%, resolved with the decrease of the dose of pomalidomide). The median number of prior treatments was 3 (range: 2-5 cycles). All patients previously received lenalidomide and an alkylating agent, only 3 patients were not exposed to bortezomib, due to severe peripheral nervous system involvement, 10 (33%) underwent autologous stem cell transplant and 9 (30%) received previous thalidomide-based regimens. The median number of PDex cycles performed was 4 (range: 1-11). Median follow-up of living patients was 8 months (IQR: 3.5-16 months) and 13 (43%) patients died due to progressive disease. Fourteen patients (47%) achieved at least partial response, with 1 complete remission (CR), and very good partial responses (VGPR) in 2 cases (6%). Cardiac responses were observed in 1 of 5 patients with measurable NT-proBNP (20%), but this can be underestimated due to the pomalidomide-related increase of NT-proBNP, and renal response in 3 of the 11 evaluable patients (27%).
Summary/Conclusions: The combination of pomalidomide and dexamethasone is well tolerated and effective in multiple myeloma-associated AL amyloidosis and can be a valuable rescue option in this high-risk population.

P685

MYOCARDIAL UPTAKE OF 99MTC-DPD IN PATIENTS WITH AL AMYLOIDOSIS

C. De Miguel[1,*], L. Llorente[1], F.J. de Haro-del Moral[2], P. García-Pavía[3], E. González-López[3], J. Segovia[3], J.A. López[4], J.M. Vázquez[4], I. Krsnik[1]
[1]Hematology, [2]Nuclear Medicine, [3]Cardiology, Hospital Universitario Puerta de Hierro Majadahonda, [4]Cardiovascular Proteomics, Centro Nacional de Investigaciones Cardiovasculares Carlos III, Majadahonda, Spain

Background: AL amyloidosis is a free light chain (FLC) deposition disease that can affect the heart. To identify the specific subtype is essential for treatment and prognosis.^{99m}Tc-DPD scintigraphy (SC) has shown high sensitivity and specificity for detecting TTR cardiac amyloidosis, although some cases have been described with AL amyloidosis and DPD uptake. An intense biventricular uptake (Perugini score 2-3 (PS)) is highly suggestive of TTR amyloidosis.
Aims: Our objective is to describe the characteristics of patients with AL amyloidosis and myocardial DPD uptake.
Methods: We reviewed all SC performed at our center in the last 50 months. Indication was ventricular hypertrophy of unknown etiology. We have correlated the image findings with the clinical and/or pathological diagnosis. AL amyloidosis diagnosis was based on histological demonstration of amyloid by Congo Red staining and immunohistochemistry (IHC) in any tissue and confirmation by proteomics (mass spectrometry (MS)) when indicated.
Results: We performed 704 SC for different indications during the study period. 41/61 patients (67.2%) with AL amyloidosisand cardiac involvement underwent a SC: 27 were negative (66%), 7 (17%) showed some degree of uptake (PS score<2 and focal or univentricular uptake) and 7 (17%) had biventricular uptake (PS 2-3). Patients with PS<2 (7): 5 patients underwent an endomyocardial biopsy (EMB). In 4 cases IHC confirmed AL amyloidosis, while in 1 case IHC was not diagnostic and MS confirmed AL amyloidosis. The two remaining patients were diagnosed of AL amyloidosis by IHC unequivocally in other tissues. Patients with PS 2-3 (7): 5 patients underwent an endomyocardial biopsy (EMB). Among them, 3 were diagnosed of AL amyloidosis, both by IHC and MS. Two patients, both of them with a M-spike and abnormal free light chains ratio in serum and increased clonal plasma cells in the bone marrow, showed TTR and faint light chain deposition but MS confirmed the diagnosis of TTR amyloidosis (TTR gene non mutated). The two remaining patients were diagnosed of AL amyloidosis by IHC unequivocally in other tissues. Mean value of NT-proBNP (N-terminal-natriuretic peptide) in patients with AL amyloidosis was 7730 pg/ml for those with a positive uptake in the scintigraphy and 9990 pg/ml for those with a negative result.
Summary/Conclusions: Cardiac 99mTc-DPD SC has been described as a useful technique in the differential diagnosis between AL and TTR amyloidosis. However, up to 30% of cases of AL amyloidosis show some degree of uptake and 10% show a pattern consistent with TTR amyloidosis (biventricular uptake and PS 2-3). Cases have been described with myocardial deposit of both TTR and light chain and up to 10-15% of the population >75 years may show a MC in serum, so it is essential to type accurately amyloid in patients with suspected AL amyloidosis and myocardial uptake in SC. MS is not routinely available in most centers and IHC results may be ambiguous. We consider that MS is mandatory in cases of cardiac amyloidosis with abnormal FLC ratio and positive biventricular ^{99m}Tc-DPD uptake. We did not find any correlation between positive uptake in the SC and NT-proBNP values, as it has been recently suggested.

P686

WHEN PERFORMANCE OF CYTOGENETICS MATTERS: A POPULATION-BASED STUDY IN THE NETHERLANDS ON NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

M. Brink[1,*], O. Visser[1], M.C. Minnema[2], S. Zweegman[3], P. Sonneveld[4], A.G. Dinmohamed[145]
[1]Department of Research, Comprehensive Cancer Center the Netherlands, [2]Department of Hematology, University Medical Center Utrecht, Utrecht, [3]Department of Hematology, VUmc, Amsterdam, [4]Department of Hematology, Erasmus MC Cancer Institute, [5]Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: It was recently shown in both clinical and population-based series that unperformed cytogenetics (UPCs) in intensively treated patients with acute myeloid leukemia was independently associated with poor prognosis, as compared to patients with performed cytogenetics.
Aims: Therefore, we set out to assess whether UPCs is associated with poor outcome in young patients with symptomatic multiple myeloma (MM) who have received induction chemotherapy.
Methods: We identified 358 newly diagnosed patients with MM <66 years in 2014 from the nationwide population-based Netherlands Cancer Registry (NCR). UPCs was used to indicate that no sample was sent in for cytogenetic analysis. Performed cytogenetics were grouped by Revised International Staging System (R-ISS), *i.e.* high-risk (presence of translocations (4;14) or (14;16) or deletion 17p) or standard-risk (presence of other aberrations or no aberrations). Only patients treated with induction chemotherapy, defined as treatment with VCD, PAD, BD or TAD +/- subsequent high dose melfalan and autologous stem cell transplantation (ASCT), were included for analyses. In total, 319 (89%, median age 60 years, 62% male) were treated with induction chemotherapy, 39 patients otherwise or had no therapy. The primary endpoint was progression-free survival (PFS), defined as time from start of first line induction chemotherapy to progression or death, whichever comes first. Patients alive without progression were censored at February 1st, 2016.
Results: In 220/319 (69%) MM patients treated with induction chemotherapy, cytogenetics was performed and 63 of these patients (29%) were cytogenetically high-risk. No statistical significant differences were observed in CRAB criteria or ISS between patients with or without performed cytogenetics. The proportion of patients undergoing ASCT was similar in different cytogenetic groups (standard-risk 85%, high-risk 83% and UPC 77%, p=0.77). Achieving partial response or better was higher, although not statistically significant, in the standard-risk group as compared to the high-risk and UPC groups (93% *vs* 89% *vs* 85%, p=0.92). Response outcome was unknown for 9% of the UPC group, 5% in high-risk group and 4% in the standard-risk group. Median follow-up time was 516 days. PFS for patients in the standard-risk group was highest, as compared to patients in the high-risk or UPCs groups after one year of follow-up (88% *vs* 81% *vs* 74%, p=0.0003).
Summary/Conclusions: Our data show that cytogenetic testing is performed in almost 70% of MM patients <66 years. Although response rates were similar for patients in the UPC, standard- and high-risk groups, PFS was better in the standard-risk group. Patients with unperformed cytogenetics had the poorest outcomes. The reasons are unclear, but a plausible explanation for not performing cytogenetics could be the patients' worse clinical condition at presentation which requires immediate treatment. For the abovementioned outcome measures, data of calendar year 2015 will be added and presented at the European Hematology Association.

P687

AN UPDATED ADJUSTED COMPARISON SUGGESTS DARATUMUMAB IS ASSOCIATED WITH PROLONGED SURVIVAL COMPARED WITH STANDARD OF CARE THERAPIES IN HEAVILY PRE-TREATED AND HIGH REFRACTORY MULTIPLE MYELOMA PATIENTS

S.K. Kumar[1,*], B.G. Durie[2], J. Diels[3], T. Bacon[4], F. Søltoft[5], A. Lam[6]

[1]Division of Hematology, Mayo Clinic, Rochester, MN, [2]Cedars-Sinai Outpatient Cancer Center at the Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA, United States, [3]Janssen Health Economics & Market Access EMEA Statistics & Modeling, Beerse, Belgium, [4]Janssen Health Economics & Market Access EMEA, Dublin, Ireland, [5]Janssen Nordic, Birkerød, Denmark, [6]Janssen Global Services, LLC, Raritan, NJ, United States

Background: To contextualize the benefit of novel agents such as daratumumab (DARA) monotherapy for the treatment of patients with heavily pretreated and highly refractory multiple myeloma (MM), it is critical to understand the real-world outcomes of this patient population on current standard of care (SOC) therapies. To determine the comparative effectiveness of DARA *vs* real-world SOC, an adjusted comparison was conducted[1] utilizing data from the DARA monotherapy trials[2] and the International Myeloma Foundation (IMF) chart review.[3]
Aims: The objective of this analysis is to update the adjusted comparison to include additional Swedish patients from the IMF chart review.
Methods: Data for patients treated with DARA 16mg/kg monotherapy were available from clinical trials MMY2002 (n=106) and GEN501 (n=42), while patients treated with SOC therapies were derived from the IMF chart review of patients with MM who had ≥3 prior lines of therapy and were double refractory to a proteasome inhibitor (PI) and an immunomodulatory drug (IMiD) (n=550, original 510, additional Swedish patients 40). Patients from the IMF-cohort who moved into further treatment lines after the line therapy where they fulfilled inclusion criteria, contributed information to the analysis for multiple lines of therapy, with baseline defined as the date of initiation of the actual treatment line, resulting in a sample size of 963 treatment lines from 550 patients. The relative treatment effect of DARA *versus* SOC was estimated using multivariate Cox regression analyses. The methodology utilized individual patient data to compare overall survival (OS). The covariates included were age, gender, prior lines of therapy, albumin, beta-2 microglobulin, prior exposure to pomalidomide and carfilzomib, and PI/IMiD refractory status. Clustering of observations at the treatment-line level within patients was controlled for using the robust sandwich estimate for the covariance matrix. Statistical significance testing was performed using a two-tailed *P*-value of <0.05, and all comparisons between treatment groups were reported with hazard ratios (HRs) and 95% confidence intervals (CIs).
Results: After adjustment for differences in baseline characteristics included in the multivariate model between the DARA and SOC groups, results showed a significant improvement in favor of DARA compared with SOC for OS (HR=0.42 [95% CI 0.31–0.57]). When limiting the comparative analysis to European patients from the IMF cohort (n=341), results for OS are very similar (HR=0.40 [95% CI: 0.28-0.58]).
Summary/Conclusions: Findings from the regression analyses using the updated IMF dataset were consistent with results from the previous analysis3 and suggest that DARA is associated with significant gains in OS compared with SOC therapies for patients with heavily pre-treated and highly refractory MM. Findings for a European subset from the IMF dataset were similar to results from the entire cohort.

Background: Multiple Myeloma (MM) is predominantly a disease of the elderly and the outcome of these patients is poorer than that of transplant candidates. It is well stablished that those considered frail or unfit have a dismal prognosis, however, even within fit patients, such as those included in clinical trials, there is substantial proportion of early deaths (within the first 2 years after diagnosis). Identification of this "high-risk" fit elderly patients could contribute both to the design of innovative clinical trials, and to avoid the emotional and economical burden of repetitive unsuccessful therapies.
Aims: To analyze the factors associated with early death (within first 2-years) due to active MM in elderly newly diagnosed (NDMM) patients fit enough to be included in clinical trials with optimized therapy with proteasome inhibitors and IMIDs.
Methods: 497 NDMM not transplant candidates treated in two prospective GEM-PETHEMA trials were included in the study: GEM05MAS65 (n=260) used frontline treatment with either bortezomib-melphalan-prednisone (VMP) or bortezomib-thalidomide-prednisone followed by maintenance with bortezomib, thalidomide or bortezomib, prednisone; the GEM2010MAS65 (n=239) compared induction with sequential or alternating cycles of VMP + lenalidomide-dexamethasone. The event was defined as death related to active MM within 2 years from diagnosis, either because of disease progression or early death due to absence of response.

Table 1.

Early death (< 2 years) due to Multiple Myeloma			
Number of patients	Yes (n=77) n (%)	No (n=420) n (%)	P
Age			
< 75 years	38 (49.3)	265 (62.8)	P = 0.026
≥ 75 years	39 (50.7)	157 (37.2)	
Response

Negative	2 (66.2)	96 (77.7)	p= 0.040
Positive	20 (33.8)	196 (22.3)	
CD27_Diagnosis			
Negative	42 (64.6)	195 (50.5)	p= 0.035
Positive	23 (35.4)	191 (49.5)	

Results: From the 497 patients included, 77 (15%) patients died within 2 years from diagnosis due to active MM. When we compared this latter cohort with the remaining patients, the profile of the high risk group was characterized (Table 1) by a higher proportion of patients >75 years, advanced ISS and R-ISS stage, higher β2-microglobuline (β2-M) levels (>3.5 and 5.5mg/dl) and abnormal LDH; increased incidence of high-risk cytogenetic features (HR CA), $CD45^-$ clonal plasma cells, and lower incidence of $CD27^+$ MM phenotype. Patients dying in <2 years were also characterized by a higher proportion of non-responding patients as well as unstained responses (unsR). The multivariate analysis showed that the risk of early death due to active MM was related to four independent prognostic factors: age >75y (p=0.008), abnormal LDH (p=0.000), ISS 3 (p=0.008), and presence of HR CA (p=0.019. These four variables enabled the definition of a scoring system composed of 6 categories (0-5) (age>75 y=1 point, ISS 3=1, LDH>normal=2, HR CA= 1). Using a cut-off point of ≥4 the positive predictive value (PPV) was 57.9%, negative predictive value (NPV) was 87.4% and the positive likelihood ratio 7.9. Upon adding the

unsR (duration of response (≥PR) <6 months) to the baseline score we were able to build a new score in which the unsR had a 3 points weight. A score punctuation ≥5 segregates a subgroup of patients with poor outcome (PPV: 83.3%, the NPV: 84.02%).
Summary/Conclusions: The risk of early death due to active disease in elderly patients was related to four independent prognostic factors: age >75y, high LDH levels, advanced ISS, and presence of HR CA. A score ≥ 4 identify a subgroup of patients with high probability of death within 2 years despite optimized treatment.

MPL ACTIVATION DIRECTLY INDUCES FIBROCYTE DIFFERENTIATION TO CAUSE MYELOFIBROSIS

Background: Myelofibrosis (MF) may be caused by various pathogenic mechanisms, such as elevated circulating cytokine levels, cellular interactions, and genetic mutations. However, the underlying mechanism of MF remains unknown. A recent study showed that the neoplastic clone of fibrocytes, spindle-shaped fibroblast-like blood cells derived from monocyte lineage, was essential in primary MF pathogenesis; serum amyloid P, which suppressed fibrocyte differentiation, markedly improved survival and MF in a murine xenograft model (J Exp Med 2016; 213: 1723-1740). Regarding cytokines, the thrombopoietin (TPO) signaling pathway was assumed to be closely associated with promoting MF. Mice transplanted with TPO-overexpressing bone marrow cells showed symptoms such as MF and splenomegaly (Blood 1997; 90: 4369-4383). Romiplostim (Rom), a TPO-receptor agonist, induced MF in rats and some immune thrombocytopenic purpura patients (Blood 2009; 114: 3748-3756). Fibrocytes and TPO played certain roles in MF pathogenesis, but the nature of their relationship remains unknown.
Aims: We investigated the relationship between myeloproliferative leukemia protain (MPL; TPO receptor) activation and fibrocyte differentiation in promoting MF. The secondary goal was to discover a unique fibrocyte marker in monocyte or macrophage population.
Methods: Murine fibrocyte cell lines were established from transgenic mice harboring the temperature-sensitive large T-antigen gene of simian virus 40 under IL-13 and M-CSF conditions. Murine fibrocyte cell lines and human peripheral blood mononuclear cells (PBMCs) were cultured with or without Rom to evaluate if MPL activation promoted fibrocyte differentiation, and the ratio of spindle-shaped cells was calculated. Rom was administered on day 1 and 8 to induce an MF-like phenotype in C57BL/6J mice, and clodronate liposomes (CLs; day −4, −1, 4, and 7) were used to eliminate monocytes and macrophages.
Results: Flow cytometric analysis revealed that all murine fibrocyte cell lines stained positive for fibrocyte cell markers, including collagen I, CD45, CD34, CD11b, and CD68. Murine fibrocyte cell lines expressed MPL and responded to Rom or murine TPO to differentiate into mature fibrocytes, specifically with a longer spindle shape and stronger collagen I expression than when cultured with IL-13 and M-CSF alone. Rom also increased the number of mice spleen cell fibrocyte colonies in the presence of IL-13 and M-CSF. The administration of 1mg/kg of Rom once a week induced an MF-like phenotype in all mice within 2–3 weeks and increased the number of fibrocytes in the spleen. Treatment with CLs eliminated fibrocyte precursors and prevented severe MF and splenomegaly. Human cultured fibrocytes also expressed MPL, and Rom increased the number of spindle-shaped fibrocytes induced from human PBMCs. The SLAMF7^{high} MPL^{high} subpopulation was clearly separated from the SLAMF7^{low} MPL^{low} population in human CD14^{+} monocytes. A significantly higher frequency of fibrocyte differentiation was observed in the SLAMF7^{high} MPL^{high} population. The number of SLAMF7^{high} MPL^{high} cells was significantly greater in MF patients than in healthy donors. Conversely, their numbers did not increase in MF patients treated with ruxolitinib.
Summary/Conclusions: MPL activation directly induced fibrocyte differentiation from monocytes and macrophages expressing MPL, and the elimination of these cells reversed the MF phenotype. Our findings confirmed a link between fibrocytes and the TPO/MPL signaling pathway and indicated that the combination of MPL and SLAMF7 could be a useful fibrocyte marker in monocytes or macrophages.

Background: Progressive bone marrow (BM) fibrosis in patients with PMF is thought to arise from non-hematopoietic stromal cells stimulated by overpro-

duced growth factors. However, in other tissues and organs, fibrosis is associated with monocyte-derived fibrocytes, which express markers of both hematopoietic and stromal cells. Recently, we have reported that clonal neoplastic fibrocytes play a role in the induction of BM fibrosis in primary myelofibrosis (PMF) (Verstovsek, J Exp Med. 2016). We demonstrated that the BM of PMF patients harbors more neoplastic, functionally distinct fibrocytes and fewer MSCs than hematologically normal bone marrow (BM). In addition, we detected an overabundance of fibrocytes in the BM and spleen of an established PMF mouse model and a xenograft mouse model of PMF created using BM-derived low-density cells from patients with PMF.
Aims: Fibrocytes, which make up <1% of BM cells, differentiate from a subpopulation of CD14+ monocytes and are recruited to sites of organ damage where they regulate tissue repair. We hypothesized that clonal neoplastic CD14+ monocytes may play a role in the induction of BM fibrosis in PMF
Methods: To test this hypothesis, we transplanted NSG mice (NOD/Scid (NoD.Cg-prkdcscid //2rgtm1wjl/SZJ) with sorted CD14+ monocytes from patients with *JAK2*^{V617F}-positive PMF or donors with hematologically normal BM.
Results: Here, we show that BM-derived CD14+ cells from patients with *JAK2*^{V617F}-positive PMF or donors with hematologically normal BM engrafted in NSG mice. Transplanted NSG mice with PMF BM-derived CD14+ monocytes developed a myelofibrosis-like phenotype with reticulin fibrosis and abundant neoplastic (*JAK2*^{V617F}) fibrocytes in the BM and spleen. Two months after transplantation, we detected a subpopulation of hCD45+ and hCD68+ cells within the HLA+ population of BM cells. In addition, we found dysplastic megakaryocytes in the BM and spleen of the PMF CD14+ transplanted mice. Immunohistochemistry staining of paraffin embedded BM sections did not detect hCD3, hCD19 or hCD34 cells. However staining with anti-human CD42b antibodies detected human megakaryocytes, suggesting that the dysplastic megakaryocytes detected in PMF CD14+ transplanted NSG mice are human-derived.
Summary/Conclusions: Taken together, our data suggest that neoplastic CD14+ monocytes contribute to the induction of BM fibrosis in PMF. What role CD14-derived megakaryocytes play in the pathogenesis of PMF remains to be determined.

ESTABLISHMENT OF AN IN VITRO MODEL FOR THE SKEWED MEGAKARYOPOIESIS BY CALRETICULIN MUTATION IN HUMAN CELLS
H. Takei[1,*], S. Mano[12], N. Masubuchi[13], Y. Mizukami[14], S. Morishita[5], M. Imai[6], Y. Edahiro[1], Y. Hironaka[1], M. Nudejima[1], S. Tsuneda[2], H. Endo[7], S. Nakamura[7], K. Eto[7], A. Ohsaka[5], M. Araki[5], N. Komatsu[1]
[1]Department of Hematology, Juntendo University Graduate School of Medicine, [2]Department of Life Science and Medical Bioscience, Waseda University Graduate School, [3]Research Institute for Disease of Old Age, Juntendo University, [4]Center for Genomic and Regenerative Medicine, [5]Department of Tranfusion Medicine and Stem Cell Regulation, [6]Leading Center for the Development and Research of Cancer Medicine, Juntendo University Graduate School of Medicine, Tokyo, [7]Department of Clinical Application, Center for iPS cell Research and Application, Kyoto University, Kyoto, Japan

Background: Somatic mutations on *calreticulin* (*CALR*) gene are found in a majority of patients with *JAK2*-unmutated *Philadelphia*-chromosome negative myeloproliferative neoplasms (MPNs). We and other groups have recently shown that mutant CALR activates the downstream pathway of thrombopoietin (TPO) receptor MPL, which induces factor-independent growth in human and murine cells. However, roles of mutant CALR in human hematopoietic cell differentiation remain largely elusive.
Aims: We aimed to recapitulate the MPN phenotypes and examine the impact of *CALR* ins5 on human hematopoietic cell differentiation *in vitro*.
Methods: We employed iPS cells (iPSC) established from an essential thrombocythemia (ET) patient and a healthy individual harboring a 5-base insertion mutant (*CALR* ins5) and wild type (*CALR* wt) *CALR* gene, respectively. Hematopoietic progenitor cells (HPCs) were produced from iPSC by "iPS-Sac" method. HPCs were then cultured to induce megakaryocytic cells (MKs) and erythroid cells defined by CD42b and CD235a, respectively. The mechanism of skewed differentiation was assessed by measuring the mRNA expression of lineage determinant genes such as *FLI1* and *KLF1*. To demonstrate the established assay system for the use of compound screening, CALR ins5-dependent megakaryopoiesis was examined by therapeutic compounds.
Results: The number of CD34+ HPCs produced from iPSC was unchanged between *CALR* ins5 and *CALR* wt genotypes, implying that *CALR* ins5 did not affect the establishment of HPC from iPSC. As expected from constitutive activation of MPL by mutant CALR, MKs were induced from *CALR* ins5-HPC even in the absence of TPO in either semi-solid or liquid culture systems, which was not evident with *CALR* wt-HPC. Unlike megakaryopoiesis, both *CALR* ins5 and *CALR* wt HPCs required EPO for the production erythroid cells. However, the number of erythroid cells induced from *CALR* ins5 HPC was significantly decreased compared to that from *CALR* wt HPC, implying that *CALR* ins5 interfered the erythroid cells differentiation from iPSC-derived HPC. This interference was seemingly caused by a premature expression of *FLI1* that blocked *KLF1* expression required for the erthroid cell differentiation in *CALR* ins5 cells. Finally, we showed that the treatment of ruxolitinib greatly reduced megakaryocytic differentiation in both *CALR* ins5 and wt HPCs, demonstrating that ruxolitinib does not possess preferential targeting of CALR ins5 cells.
Summary/Conclusions: We have established an *in vitro* model system that recapitulates the megakaryocytosis caused by mutant CALR, which should be useful tool for the examination of therapeutic strategies against MPN patients harboring CALR mutation.

P692

QUANTITATIVE PROTEOME HETEROGENEITY IN MYELOPROLIFERATIVE NEOPLASM SUBTYPES AND ASSOCIATION WITH JAK2 MUTATION STATUS
N. Socoro Yuste[1,*], C. Vladan P[2], J. Mondet[1], I. Plo[3], P. Mossuz[1,4]
[1]TIMC-IMAG Laboratory - TheREx team, GRENOBLE, France, [2]Institute for Medical Research, Belgrade, Serbia, [3]INSERM, UMR1170. Gustave Roussy, Paris, [4]Laboratoire d'Hématologie cellulaire - Institut de Biologie et Pathologie, GRENOBLE, France

Background: Apart from well-known genetic abnormalities, several studies have reported variations in protein expression in Philadelphia negative (Ph-) Myeloproliferative Neoplasm (MPN) patients that could contribute towards their clinical phenotype.
Aims: In this context, a quantitative mass spectrometry proteomics protocol was used to identify differences in the granulocyte proteome with the goal to characterize the pathogenic role of aberrant protein expression in MPNs.
Methods: LC MS/MS (LTQ Orbitrap) coupled to iTRAQ labeling showed significant and quantitative differences in protein content among various MPN subtypes [polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF)], and according to the genetic status of JAK2 (*JAK2V617F* presence and *JAK2V617F* allele burden).
Results: A number of differentially expressed proteins were identified with the most frequent being members of the RAS GTPase family and oxidative stress regulatory proteins. Subsequent analysis found that calreticulin (CALR), known to be involved in calcium homeostatsis and apoptotic signaling, was overexpressed in *JAK2V617F* granulocytes compared with *JAK2 wild-type* and independently of the *JAK2V617F* allele burden. Finally it was demonstrated, in a Ba/F3 cell model, that increased calreticulin expression was directly linked to *JAK2V617F* and could be regulated by JAK2 kinase inhibitors.
Summary/Conclusions: In conclusion, these results reveal proteome alterations in MPN granulocytes depending on the phenotype and genotype of patients, highlighting new oncogenic mechanisms associated with *JAK2* mutations and overexpression of calreticulin.

P693

THE NOVEL SWITCH CONTROL INHIBITOR DCC-2618 COUNTERACTS GROWTH AND SURVIVAL OF VARIOUS NEOPLASTIC CELLS, INCLUDING MAST CELLS, EOSINOPHILS, AND MONOCYTES, IN PATIENTS WITH SYSTEMIC MASTOCYTOSIS
M. Schneeweiss[1,2,*], B. Peter[1,2], S. Bibi[3], K. Blatt[1,2], M. Jawhar[4], D. Berger[2], G. Stefanzl[2], S. Herndlhofer[1,2], W. R. Sperr[1,2], E. Hadzijusufovic[1,2,5], K.V. Gleixner[1,2], A. Reiter[4], M. Arock[3], P. Valent[1,2]
[1]Ludwig Boltzmann Cluster Oncology, [2]Department of Internal Medicine I/Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, [3]Laboratoire de Biologie et Pharmacologie Appliquee, CNRS UMR 8113, Ecole Normale Supérieure de Cachan, Cachan, France, [4]Department of Hematology and Oncology, University Medical Centre Mannheim, Mannheim, Germany, [5]Department for Companion Animals and Horses/Clinic for Internal Medicine and Infectious Diseases, University of Veterinary Medicine Vienna, Vienna, Austria

Background: Systemic mastocytosis (SM) is a myeloid neoplasm defined by abnormal growth and pathologic accumulation of neoplastic mast cells (MC) in various internal organs. The indolent variant of SM (ISM) is associated with an almost normal life expectancy. By contrast, the prognosis in advanced SM, including SM with an associated hematologic neoplasm (SM-AHN), aggressive SM (ASM), and MC leukemia (MCL) is poor with short survival times. Most patients with SM express the D816V-mutated variant of *KIT*, which confers resistance against several tyrosine kinase inhibitors (TKI), including imatinib. DCC-2618 is a novel switch control inhibitor that has been described to block the kinase activity of KIT D816V.
Aims: The aims of this study were to evaluate the effects of the switch control inhibitor DCC-2618 on proliferation and survival of neoplastic MC and other neoplastic and non-neoplastic cell types that may play a role in advanced SM and often expand in AHN patients.
Methods: For our *in vitro* studies we used different human MC lines (HMC-1.1, HMC-1.2, ROSA^{KITWT}, ROSA^{KITD816V}, ROSA^{KITK509I}, MCPV-1.1, MCPV-1.2, MCPV-1.3 and MCPV-1.4) and primary neoplastic MC obtained from patients with SM. In addition, the acute myeloid leukemia (AML) cell lines

MOLM-13, MV4-11, KG-1 and U-937, the eosinophilic leukemia cell line EOL-1, human cultured umbilical vein endothelial cells (HUVEC), the microvascular human endothelial cell line HMEC-1 and primary neoplastic cells obtained from patients with AML, chronic myelomonocytic leukemia (CMML) and (clonal or reactive) hypereosinophilia were used. Cell proliferation was quantified by ^{3}H-thymidine uptake. Apoptosis was determined by flow cytometry and light microscopy. The phosphorylation-status of KIT and BTK was analyzed by Western blotting. The effects of DCC-2618 on histamine secretion in basophils (BA) were analyzed by histamine release assay.

Results: DCC-2618 was found to block the proliferation of all MC lines tested, with lower IC_{50} values measured in *KIT* D816V-negative HMC-1.1 cells (12.3±3.7 nM) and ROSA^{KITWT}cells (41±5 nM) than in *KIT* D816V-positive HMC-1.2 cells (123±36 nM), ROSA^{KITD816V} cells (168±65 nM), and the multi-resistant MC line MCPV-1. The DCC-2618-metabolite DP-5439 showed comparable growth-inhibitory effects in all cell lines tested. DCC-2618 was also found to inhibit proliferation of primary neoplastic MC obtained from patients with ISM, ASM or ASM-AHN and MCL (IC_{50}: 83-460 nM). DCC-2618 induced apoptosis and blocked tyrosine phosphorylation of KIT in all MC lines tested. We were also able to show that DCC-2618 inhibits proliferation and survival in the eosinophilic leukemia cell line EOL-1 (IC_{50} 1.8±1.3 nM) and the *FLT3* ITD-mutated AML cell lines MV4-11 (IC_{50} 147±88 nM) and MOLM-13 (IC_{50} 132±95 nM). In addition, DCC-2618 was found to block proliferation in primary leukemic cells in patients with monoblastic AML and CMML which are the most prevalent types of AHN in advanced SM. DCC-2618 was also found to inhibit growth of cultured human vascular endothelial cells, suggesting that the drug may also counteract SM-related angiogenesis. Finally, DCC-2618 was found to inhibit anti-IgE-induced histamine release from normal BA in a dose-dependent manner (IC_{50}: 1-10 μM).

Summary/Conclusions: DCC-2618 is a new potent switch control TKI that counteracts growth and survival of neoplastic MC, leukemic monocytes, AML blasts, eosinophils, and endothelial cells *in vitro*. Whether DCC-2618 is able to block growth of neoplastic MC and other involved lineages in patients with advanced SM is currently being ascertained in a clinical trial (NCT02571036).

P694

DISTRIBUTION OF MUTATIONS IN DRIVER AND NON-DRIVER GENES ACCORDING TO CLONAL HEMATOPOIESIS IN ESSENTIAL THROMBOCYTHEMIA AND POLYCYTHEMIA VERA

A. Senín[1,2,*], B. Bellosillo[2,3], C. Fernández-Rodríguez[2,3], L. Camacho[2,3], C. Besses[1,2], A. Álvarez-Larrán[1,2]

[1]Hematology Department, Hospital del Mar-IMIM. Universitat Autónoma de Barcelona, [2]Group of Applied Clinical Research in Hematology. Cancer Research Program, IMIM, [3]Pathology Department, Hospital del Mar-IMIM. Universitat Pompeu Fabra, Barcelona, Spain

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are clonal myeloid disorders that originate from a multipotential hematopoietic stem cell. Although most women with PV and ET have mutations in *JAK2V617F, CALR* or *MPL*, the proportion of patients presenting clonal hematopoiesis by X chromosome inactivation patterns (XCIP) is variable and its relationship with the presence of non-driver mutations is not well known.

Aims: To study the distribution and dominance of driver and non-driver mutations in the development of clonal hematopoiesis.

Methods: One hundred and twenty-six women (PV n=33, ET n=93) with an informative result of XCIP based on *HUMARA* assessment were included in the study. *HUMARA* analysis was performed by studying the degree of methylation of exon 1 in granulocytes and lymphocytes. Somatic mutations were studied in DNA extracted from granulocytes by NGS using a panel of 51 myeloid-related genes.

Results: Median age of patients at the time of *HUMARA* analysis was 64 years (range:21-92). Mutations in *JAK2* were present in 62% of them, *CALR* in 11%, *MPL* in 8%, and 14% were triple negative (TN). Non-driver mutations were detected in 45 patients (17 PV and 28 ET). The most frequently mutated genes were *TET2* (16%), *DNMT3A* (8%), *ASXL1* (5%), *SF3B1* (5%), *EZH2* (2%) and *RUNX1* (2%).The mutation with the highest variant allele frequency (VAF) was considered the dominant mutation and it corresponded to a driver mutation in 92 patients (*JAK2* n=70, *CALR* n=13, *MPL* n=8) and a non-driver mutation in 9 patients (3 TN cases with *TET2* mutations, 1 TN patient with *TP53* mutation and 4 *JAK2*-mutated patients with mutations in *TET2, CBL, DNMT3A* or *EZH2*). In 12 cases the VAF of the driver mutation (*JAK2* n=9, *CALR* n=1, *MPL* n=2) was similar to the non-driver mutation, being *TET2* the codominant mutation in 6 of them. *HUMARA* analysis was clonal in 66 patients and polyclonal in 60 patients. Clonality was more frequently observed in PV (76%) than in ET (44%, p=0.002). Clonal *HUMARA* was observed in 90% of *MPL*-mutated patients in comparison with 58% in *JAK2*-mutated, 42% in *CALR*-mutated and 11% in TN (p<0.0001). Two patients with TN ET showing clonal hematopoiesis had *TET2* mutations. In *JAK2*-mutated women, the mutant allele load was significantly higher in clonal than in polyclonal cases (43% *vs* 23%, p=0.02) and in PV than in ET (76% *vs* 47%, p=0.01). Eighty percent of patients with non-driver mutations showed *HUMARA* clonality *vs* 37% of patients without non-driver mutations (p<0.0001). The mutated genes significantly associated with a higher frequency of clonal hematopoiesis were *TET2* (p=0.007) and *SF3B1* (p=0.029). Age was significantly associated with clonal hematopoiesis and with the presence of non-driver mutations (median age of 55 and 68 years for polyclonal and clonal *HUMARA* respectively, p<0.0001 and 57 and 71 years for patients without and with additional mutations respectively, p<0.0001). Patients in which the driver mutation was dominant were younger than those in which the non-driver mutation was dominant or codominant (median age 61 *vs* 71 years, p=0.01). In the multivariate analysis, the variables that were associated with a higher probability of clonal hematopoiesis were the presence of non-driver mutations (OR:4.2, 95%CI: 1.6-10.6, p=0.003), age> 65 years (OR:2.7, 95%CI: 1.2-6.5, p=0.02), *MPL* genotype (OR:10.9, 95%CI: 1.2-98.9, p<0.0001) and PV diagnosis (OR 3.6, 95%CI: 1.3-9.7, p=0.01).

Summary/Conclusions: The presence of non-driver mutations is associated with clonal hematopoiesis regardless of age and type of disease.

Elderly patients with clonal hematopoiesis often show non-driver mutations coexisting in equal or greater proportion than the driver mutation suggesting that MPN has originated on preexisting clonal hematopoiesis.

P695

RUXOLITINIB/NILOTINIB/PREDNISOLONE COMBINATION: A PROMISING NOVEL TREATMENT FOR MYELOFIBROSIS

A. Arenas[1], R. Ayala[1], M. Gallardo[1], J. Martínez-López[1,*]

[1]Hematology, Hospital 12 de Octubre, Madrid, Spain

Background: Myelofibrosis (MF) is the myeloproliferative neoplasm chromosome Phi- negative with worst prognosis. MF is characterized by stem cell-derived clonal myeloproliferation and reactive cytokine-driven inflammatory bone marrow fibrosis. Ruxolitinib is the first line treatment for MF. It was associated with significant reduction in symptomatic splenomegaly and improved constitutional symptoms. In a previous work (Arenas *et al.* Blood Volume 122, Issue 21 (ASH Annual Meeting Abstrat)) we identified a set of promising synergistic drugs combinations for a ruxolitinib. Nilotinib and prednisolone were selected from them.

Aims: The aim of this work is the study the effect of the combination of ruxolitinib, nilotinib and prednisolone in hematopoietic progenitor cells from patients with MF.

Methods: A ruxolitinib, nilotinib and prednisolone dose-response curves and synergistic studies were performed in hematopoietic progenitors CD34$^+$ from five MF patients. We studied the molecular effect of single drugs and in combination on SET2 cell line with western blot. To adress the antifibrogenic activity of the drugs and their combinations, we pre-incubated HS27 cultures with 100nM of ruxolitinib, 1 μM of nilotinib, 1 μM of prednisolone or their combination during 1 h. After that, we added 2ng/mL TGF-β during 24h to induce fibrogenesis. Finally, the collagen I expression was evaluated by immunocytochemistry (ICC).

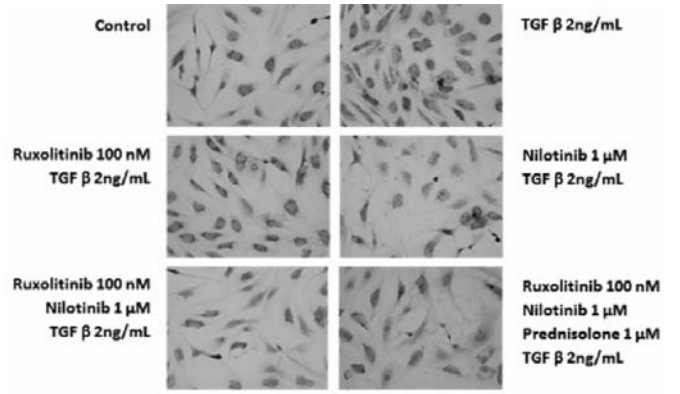

Figure 1: Collagen I expression was evaluated by ICC in HS27 treated with ruxolitinib, nilotinib, prendisolona and their combinations.

Figure 1.

Results: The effects of ruxolitinib, nilotinib and prednisolone resulted in an EC_{50} value of 55nM, 6.6μM and 13.1μM, respectively. A combination index (CI) of less than 1 indicated synergy. All combination had a synergistic behavior (Table 1); moreover, there were two combinations whose CI from all samples indicated synergy: 32nM ruxolitinib, 8 μM Nilotinib plus 0.8 μM prednisolone (CI=0.25±0.11) and 32nM ruxolitinib plus 0.8 μM prednisolone (CI=0.45±0.11). The JAK/STAT signaling pathway was inhibited: the phosphorylation of STAT5 was inhibited by ruxolitinib in 83.2±10.8 % (p-valor<0.05) regarding to control at 30 min and it was maintained at 3 hours (p-valor<0.05). The combinations 32nM ruxolitinib plus 1.6 μM nilotinib (RN) and 32nM ruxolitinib, 1.6μM nilotinib plus 0.8μM prednisolone (RNP) inhibited more than 50% of the phosphorylation of STAT5 at 30 min and maintained at 3 hours. The MAPK signaling pathway was inhibited at 30 min, the phosphorylation of ERK was inhibited in 77.7±16.4

% (p-value<0.05) by ruxolitinib, 42.6±14.4 % by RN and 70.8±11.2 % by RNP (p-valor<0.001). The inhibition was maintained at 3 hours by ruxolitinib (71.3±18.9%) (p-value<0.05). The Akt/PI3K signaling pathway seemed to begin to inhibit at 3 hours by ruxolitinib (57.5+25.2%), nilotinib (38.4±26.8%), RN (30.5±24.03%) and RNP (37.4±16.5%). Then, the antifibrogenic activity of the drugs and their combinations were studied. Nilotinib reduced the mRNA expression of COL1 (39.8±0.9 %) (p-value<0.05). Its combination with ruxolitinib (RN: 48.1±2.9% (p<0.05) and prednisolone (RNP: 37.8±1.9% (p-value<0.05). These results were corroborated by ICC: the inhibition of expression of collagen I was more intense if the HS27 were treated with nilotinib or RN (figure 1).

Summary/Conclusions: In conclusion, ruxolitinib, nilotinib, prednisolone and their combinations had a synergistic behavior to control the proliferation of myeloid cells in MF patients; moreover, they had anti-fibrotic activity in fibroblast cells. For these reasons, the combined ruxolitinib/nilotinib/prednisolone could be a promising therapy to MF and support an ongoing clinical trial in MF patients.

Background: Next-generation sequencing (NGS) technology is being implemented in clinical practice for assessing the mutational status of myeloid neoplasms. The Working Group on Molecular Biology from the Spanish Society of Hematology has performed an interlaboratory assessment of gene mutation analysis by targeted NGS.

Aims: To assess the technical performance of mutation detection by targeted NGS using myeloid panels.

Methods: The technical comparison was established on two rounds with samples previously analysed using NGS panels, Sanger sequencing and/or fragment analysis. First, four DNA samples (S1-S4) from AML patients were shared among 6 laboratories. In a second round, five samples (S5 to S9) were shared among 14 laboratories. The center of origin had previously characterized and confirmed: for the first round, 14 relevant mutations in 10 genes; and for the second round 17 relevant mutations in 7 genes. Each center performed library preparation, sequencing and blind variant analysis following their own routine practice. Detected variants and data regarding main methodological parameters were collected. Detection rate was calculated as the number of laboratories with positive detection out of the number of laboratories that sequenced the particular gene region.

Results: Eight different gene panels were used for library preparation (predesigned in 10 labs and custom in 4). The predominant approach was amplicon enrichment (11/14, 78.6%) and only 3/14 laboratories (21.4%) used capture-based methods. Sequencing was performed with Illumina devices in 9/14 laboratories and Ion Torrent platforms in 5/14. Alignment and variant calling was performed with MiSeq Reporter (n=3), Torrent Suite (n=4) or panel-adjusted analysis pipelines. The median coverage was 2353 reads (range 275-17096). Results are summarized in the table. Overall, most variants were detected by ≥80% of the laboratories. None of the participants was able to detect all the previously characterized mutations using only NGS myeloid gene panels. Variants with lower detection rates can be classified in 3 groups: a) Medium-long insertions/deletions. *FLT3*-ITD was not detected by NGS. *CALR*L367fs and *ASXL1*E635fs were detected in only 67% and 31% of laboratories, respectively. However, a *SRSF2* 24bp deletion with similar characteristics showed a 90% detection rate. b) Mutations with low variant allele frequency (VAF). *CBL*Y371N (VAF 5.24%) and *SF3B1*K700E (VAF 4.09%) were less detected/reported. c) *ASXL1*G646fs. This mutation caused by a guanine duplication in a homopolymeric region is technically challenging and there is controversy as previous reports have considered this alteration as an artifact. The reported VAFs were similar for SNVs whereas for indels higher differences were observed (mean coefficient of variation of 11.91%, and 26.04%, respectively).

Table 1.

Summary/Conclusions: Gene mutation analysis by targeted NGS in myeloid malignances is highly reproducible between laboratories and allows a comprehensive characterization of the molecular profile. However, medium-long indels, low frequency mutations (<10%), *ASXL1*G646fs detection and variant categorization are critical points that have to be addressed to improve the results. Test system validation is crucial for the implementation of NGS technology.

P697

METHYLATION AGE IN MPN PATIENTS AS A CORRELATE FOR DISEASE STATUS, ALLELE BURDEN AND THERAPEUTIC RESPONSE

Background: Myeloproliferative Neoplasms (MPNs) result from genetic and epigenetic dysregulation. Epigenetic therapies, such as Vorinostat (SAHA, MK-0683), a histone deacetylase inhibitor, have been tested as a therapeutic strategy in these patients. Examining the epigenetic landscape in MPN may provide new insights into predicting therapeutic response and therefore enhance the clinical utility of these agents. Probably the best described epigenetic mechanism is DNA methylation (DNAm); in which methyl groups are added to DNA at CpG sites regulating chromatin compaction and gene expression/repression. DNAm is known to be altered by ageing and can reflect the effect of diet, lifestyle or disease on cellular processes. Therefore 'methylation age' (MA) may be a more accurate reflection of disease than 'chronological age' (CA), which is merely a description of how long a person has been alive. Weidner *et al (Genome Biology, 2014)* described how the measurement of DNAm levels at CpGs within 3 genes, *ASPA, ITGA2B, PDE4C* enabled the determination of a reliable MA that reflected CA in normal individuals.

Aims: The aim of our study was correlate MA with disease status, mutational profile and therapeutic response in a cohort of MPN patients treated with Vorinostat.

Methods: MA was calculated following pyrosequencing of bisulfite converted DNA from 40 MPN patients on an investigator initiated non randomised open label phase II multicentre study of Vorinostat (EudraCT #2007-005306-49). Paired samples were analysed at trial entry and after 3 months of therapy to calculate their individual MA scores. Validation of methods used and ageing signature calculation was carried out using cell line and healthy volunteer material.
Results: Samples from 18 Essential Thrombocythaemia (ET) and 22 Polycythaemia Vera (PV) patients (23 F/17 M) with a mean age of 62 years (range 29-81) were assessed. *JAK2V617F* was detected in 77.5% (n=31/40). Complete clinical response (CR) was achieved in 8 patients, partial (PR) in 17, and no response (NR) in 15 patients. MA was on average 8.3 years younger than CA (range -43.4 to +41.6) at time of trial entry and 8.2 years younger (range -36.5 to +33.3) after therapy. This difference between MA and CA was greater in ET patients compared to PV, both at trial entry (-14.0 years *vs* -3.7) and after therapy (-13.0 years *vs* -4.3). A statistically significant link between *JAK2* allele burden and MA was seen: compared to patients with low or no *JAK2* allele burden, patients with high *JAK2* (>60% at baseline) had an older MA at trial entry (64.2 years *vs* 44.5, p=0.0007) and after therapy (64.3 years *vs* 44.6, p=0.0015). This difference was also seen when PV or ET patients were examined separately. Patients with a high *JAK2* allele burden tended to have a MA closer to their CA at trial entry (-0.6 years *vs* -15.3, p=0.0122) and after 3 months therapy (-0.5 years *vs* -15.2, p=0.0072). Although the cohort size was small, within the ET group, NR compared to PR was associated with a younger MA after therapy (41.4 years *vs* 56.3, p=0.0156). Within PV, NR compared to PR was associated with a MA that was older than CA both before (+9.2 years *vs* -14.2 years, p=0.0346) and after therapy (+7.4 years *vs* -13.9, p=0.0347).
Summary/Conclusions: This study suggests a link between MA and *JAK2* mutant allele burden in MPN patients, suggesting that allele burden not only has a role in clinical phenotype and disease evolution but in the overall methylation landscape of the mutated cells. However, the role of MA with respect to therapeutic response needs to be clarified with further studies required to show its full impact.

P698

ELUCIDATING THE AGE INDUCED HEMATOPOIETIC CELL-INTRINSIC AND EXTRINSIC MECHANISMS IN MYELOPROLIFERATIVE NEOPLASM INITIATION AND PROGRESSION

N.R. Tata[1,*], S. Radek[1]
[1]Department of Biomedicine, University Hospital Basel, Basel, Switzerland

Background: The number of detectable somatic mutations increase with age, but this increase is surpassed by the rise in the incidence of cancer in older people. The underlying mechanisms for this disparity remain to be elucidated. Myeloproliferative neoplasm (MPN) is an ideal malignancy model disease to study clonal hematopoiesis, disease initiation and progression during natural aging because the majority of the relevant mutations (such as JAK2 V617F) are catalogued, the disease evolves and progresses slowly allowing the collection of serial samples, and an inducible transgenic mouse models for the disease have been established. Nonetheless, the prevalent occurrence of such clonal events in aged individuals brings up the question, which age-associated factors contribute to initiate hematologic malignancies and what are the rate limiting steps attributable for age-induced myeloid malignancies? We hypothesize that aging induced alterations provides a context that favors acquisition of new mutations, selection for pre-malignant clones, and that activation of mutant JAK2 further augments these changes for increased MPN incidence in aged individuals. Thus, delineation of age associated cellular and molecular mechanisms attributable for increased prevalence of myeloid malignancies will be essential for the development of strategies for early detection and therapeutic targeting of myeloid malignancies.
Aims: The goal of this proposal is to identify age associated hematopoietic cell-intrinsic and cell-extrinsic factors that determine initiation and progression of MPN at young *versus* old age in mouse models carrying a JAK2-V617F or JAK2-exon12 mutation
Methods: To assess the effcet of aging on MPN initiation and progression we studied the young and aged inducible transgenic mouse models of MPN. Integreated omics analysis was peroformed on MPN initiating stem and progenitor cells.
Results: Our results suggest that age related changes in expression patterns resembling MPN can be found in aged wildtype mice. The mutational profiles in patients with pediatric MPN appear to be less complex than in older MPN patients. We are currently investigating the relative contributions and collaborations of age-associated cell intrinsic and extrinsic changes in HSCPs and BM niche in the course and severity of MPN in mouse models carrying a JAK2-V617F mutation, and in naturally aged donors and recipients of bone marrow transplantations.
Summary/Conclusions: Our study provided novel molecular and cellular mechanisms underlying increased incidence of MPN manifestation in old age.The implications of this work goes beyond the MPN malignancy and the comprehensive data sets generated in study will serve as a model to the wider scientific community to study other types of malignancies. This knowledge ultimately will help to define novel strategies to delay or target the onset of MPN in an aging individual.

Myeloproliferative neoplasms - Clinical 2

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly, debilitating constitutional symptoms, and progressive cytopenias. The approved JAK inhibitor ruxolitinib reduces splenomegaly and symptoms in pts with MF, but is associated with dose-limiting cytopenias and not indicated for pts with platelets <50,000/μL. Red blood cell (RBC) transfusions are the core treatment strategy for anemia in many pts. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. In 2 phase 3 studies (PERSIST-1, PERSIST-2), PAC has demonstrated significant and sustained spleen volume reduction (SVR) and symptom control *vs* best available therapy (BAT), regardless of baseline (BL) platelet count.
Aims: This analysis is focused on anemia (at BL and treatment-emergent [TE]) in pts from PERSIST-2, a phase 3 trial of PAC *vs* BAT, including ruxolitinib, in pts with MF and BL thrombocytopenia.
Methods: Pts with MF and BL platelet count ≤100,000/μL were randomized (N=311) 1:1:1 to PAC 400mg once-daily (QD), PAC 200mg twice-daily (BID), or BAT (including ruxolitinib). The co-primary endpoints were the rates of pts achieving ≥35% SVR (by MRI/CT) and ≥50% reduction in total symptom score (TSS; MPN-SAF TSS 2.0) at week 24. Efficacy analyses used the intent-to-treat efficacy population, which included all pts with randomization date allowing them to contribute data for a week 24 end point. The safety population included all pts who received any PAC or BAT (including those who had watchful waiting only). Clinical improvement in hemoglobin (hgb) was defined based on IWG criteria and RBC transfusion end points were defined according to Gale criteria (Table 1).

Table 1.

Table. Efficacy and Safety Outcomes – Spotlight on Anemia

	PAC QD	PAC BID	BAT
Intent-to-treat efficacy population, n	**75**	**74**	**72**
BL hgb <10 g/dL, n (%)	45 (60)	44 (59)	41 (57)
Clinical improvement in hgb[a] at week 24, n (%)	6 (13)	11 (25)	5 (12)
Increase in hgb ≥2 g/dL at week 24, n (%)	3 (7)	5 (11)	2 (5)
Not RBC-TI[b] at BL, n (%)	37 (49)	36 (49)	35 (49)
Reduced transfusion-dependency[c] at week 24, n (%)	7 (19)	8 (22)	3 (9)
RBC-TD[d] at BL, n (%)	17 (23)	14 (19)	14 (19)
RBC-TI[b] at week 24, n (%)	1 (6)	1 (7)	0
SVR ≥35% at week 24, n (%)	11 (15)	16 (22)	2 (3)
Pts with BL hgb <10 g/dL, n/N (%)	7/45 (16)	9/44 (20)	0/41
Pts with BL hgb ≥10 g/dL, n/N (%)	4/30 (13)	7/30 (23)	2/31 (6)
Pts RBC-TD[d] at BL, n/N (%)	1/17 (6)	4/14 (29)	0/14
Pts not RBC-TD[d] at BL, n/N (%)	10/58 (17)	12/59 (20)	2/58 (3)
TSS reduction ≥50% at week 24, n (%)	13 (17)	24 (32)	10 (14)
Pts with BL hgb <10 g/dL, n/N (%)	6/45 (13)	12/44 (27)	5/41 (12)

Serious TEAE of anemia, n (%)	5 (5)	8 (8)	3 (3)
Dose reduction due to anemia, n (%)	4 (4)	1 (1)	0
Dose interruption due to anemia, n (%)	4 (4)	5 (5)	1 (1)
Discontinuation due to anemia, n (%)	2 (2)	3 (3)	0

TEAE, treatment-emergent adverse event.
[a]A ≥2 g/dL increase at week 24 or becoming RBC-TI for ≥8 weeks prior to week 24.
[b]No RBC transfusions for 3 months. Not RBC-TI at BL indicates pts with transfusion burden who did or did not meet definition of RBC-TD.
[c]A ≥50% decrease in average number of RBC transfusions per month for 3 months.
[d]An average of ≥2 RBC units/month for the preceding 3 months.
[e]Including 19 patients who had watchful waiting only.

Results: At BL, 59% of pts had anemia (hgb <10 g/dL); pts with BL anemia were more likely at BL to have platelet count <50,000/µL (51% *vs* 38%), primary MF (71% *vs* 57%), and high DIPSS score (41% *vs* 14%). For those with BL anemia regardless of whether RBC transfusion-dependent (TD), PAC did not worsen hgb levels and the rate of clinical improvement in hgb was higher for pts in the PAC BID arm (25%) *vs* PAC QD (13%) or BAT (12%) arms (Table). For the 49% of pts not RBC-transfusion independent (TI) at BL, reduction in RBC transfusion-dependency was achieved at higher rates with PAC QD (19%) and PAC BID (22%) *vs* BAT (9%); 2 PAC and 0 BAT pts achieved RBC-TI by week 24. In PAC pts, SVR ≥35% and TSS reduction ≥50% were observed regardless of BL anemia or RBC-TD (Table). At BL, 16% of pts in the safety population had grade 3 anemia. Incidence of TE anemia was highest during the first 16 weeks of PAC (20% and 9% weeks 1-8, 9% and 13% weeks 8-16 for QD and BID, respectively) and first 8 weeks of BAT (10%). For pts with BL hgb <10 *vs* ≥10g/dL, incidence of grade 3/4 TE anemia was similar with PAC QD (26% *vs* 28%, respectively), and lower in pts with BL hgb ≥10 g/dL with PAC BID (26% *vs* 16%) and BAT (20% *vs* 7%). All instances of TE serious anemia with PAC or BAT (Table) were in pts with BL hgb <10g/dL. Dose modifications or discontinuations due to anemia were uncommon (Table). No exposure-response relationship was evident for grade ≥2 TE anemia.

Summary/Conclusions: In pts with MF and BL thrombocytopenia, PAC treatment demonstrated SVR and symptom control, regardless of BL anemia or transfusion burden. PAC treatment led to clinical improvement in hgb and reduction of RBC transfusion needs *vs* BAT. Serious anemia, and dose modifications due to anemia were uncommon. PAC provides a treatment option for pts with MF, including those with BL thrombocytopenia and anemia, for whom available options are limited.

COMBINATION THERAPY OF POMALIDOMIDE PLUS RUXOLITINIB IN MYELOFIBROSIS: RESULTS FROM COHORT 1 OF THE MPNSG-0212 TRIAL (NCT01644110)

F. Stegelmann[1,*], M. Griesshammer[2], S. Koschmieder[3], A. Reiter[4], A. Hochhaus[5], F. Heidel[5], N. von Bubnoff[6], T. Kindler[7], H. Hebart[8], M. Bangerter[9], D. Wolleschak[10], R. Möhle[11], C. Scheid[12], R. Reim[1], U. Sutter[1], K. Vetter[1], H. Döhner[1], K. Döhner[1]

[1]University Hospital of Ulm, Ulm, [2]University of Bochum, Minden, [3]RWTH Aachen University, Aachen, [4]University Medical Center Mannheim, Mannheim, [5]Jena University Hospital, Jena, [6]University Hospital of Freiburg, Freiburg, [7]University Hospital of Mainz, Mainz, [8]Stauferklinikum Mutlangen, Mutlangen, [9]Hematology and Oncology Practice, Augsburg, [10]University Medical Center Magdeburg, Magdeburg, [11]University Tübingen, Tübingen, [12]University of Cologne, Cologne, Germany

Background: Therapeutic options to address anemia in patients (pts) with Myelofibrosis (MF) are limited. In our MPNSG-0109 trial investigating pomalidomide (POM) in MF with cytopenia, anemia was improved in 14-29% of pts treated with 0.5-2mg POM once daily (QD) (Schlenk RF, Stegelmann F *et al.*, Leukemia 2016).

Aims: To evaluate synergistic effects of POM plus ruxolitinib (RUX), we are currently investigating the combination therapy within the MPNSG-0212 trial (NCT01644110).

Methods: MPNSG-0212 is designed as multicenter, single-arm phase-Ib/II trial with a target population of 38 pts in the first cohort. Primary endpoints are response rate after 12 cycles (28 days each) according to IWG-MRT (Tefferi *et al.*, Blood 2006) and red blood cell (RBC) transfusion independence criteria (Gale *et al.*, Leuk Res 2011). Secondary endpoints are safety, quality of life, progression-free, and overall survival. Main inclusion criterion is MF with anemia (Hb <10 g/dL and/or RBC transfusion dependency). While POM is given at the fixed dosage of 0.5mg QD, RUX is started at 10mg twice daily (BID) with dose modifications being allowed.

Results: Safety and efficacy data from 38 pts are presented. Median age of the pts is 73 years (range, 49-83); 19 pts (50%) previously received hydroxyurea, RUX, EPO, POM, and/or corticosteroids. Median hemoglobin (Hb) level at study entry was 8.6 g/dL (range, 5.4-11.7); 11 pts (29%) were RBC-transfusion-dependent. Median spleen size by ultrasound was 17.9 cm (range, 12.6 - 28). At baseline, 30 pts (79%) had constitutional symptoms. Mutations of *JAK2*, *MPL,* and *CALR* were present in 28 (74%), 3 (8%), and 7 (18%) pts, respectively; 26 (68%) were intermediate-2 risk and 9 (24%) high-risk according to the DIPSS (Passamonti et al, Blood 2010). Median time on treatment was 12 cycles (range, 2-33). In total, 881 adverse events (AE) CTCAE °1-5 were recorded. Worsening of anemia within the first 6 cycles was the most frequent AE occurring in 13 pts (34%) followed by fatigue in 12 (32%). Treatment interruptions were rare. There were 29 serious AE (SAE) CTCAE °2-5: most frequently, leukemic transformation (n=4), pneumonia (n=3), thoracic pain (n=3), abdominal pain (n=2), cardiac decompensation (n=2) and septic shock (n=2) occurred in 13 pts (34%) of which 5 were fatal (cardiac decompensation, pneumonia, AML and septic shock [n=2]); 5 SAE (Hb, °4; neuropathy, °3, hepatotoxicity, °3; fatigue, °3; and cardiac decompensation, °3) were considered study-related. 16 pts (42%) are currently on study treatment; 22 (58%) discontinued because of AE (n=6), withdrawal of consent (n=5), stable disease (SD) without objective response after 12 cycles (n=4), leukemic transformation (n=4) or death (n=3); 13 pts (34%) responded with spleen reduction (n=9) or ≥2 g/dL Hb increase / RBC transfusion independence (n=4). Of note, mean Hb increased continuously from 8.7 g/dL at baseline to 9.2 g/dL at the end of cycle 12; 12 pts (31%) continued treatment beyond cycle 12 because of response or SD plus clinical benefit (Hb increase <2g/dL, prolongation of transfusion intervals and/or improvement of symptoms); 6 pts (16%) stayed on treatment for >24 cycles.

Summary/Conclusions: In our study in advanced MF, combination of POM plus RUX was feasible with an objective response rate of 34%. Approximately one third of pts was treated beyond cycle 12 due to sustained therapeutic benefit. Based on the favourable safety profile and on results from our MPNSG-0109 trial, a step-wise increase of the POM dosage is intended for the 2nd study cohort to further improve anemia response.

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly, debilitating constitutional symptoms, and progressive cytopenias (anemia and thrombocytopenia). Currently, JAK1/2 inhibitor RUX is the only approved therapy for pts with MF. Although RUX has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias and is not indicated for pts with platelets <50,000/µL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. In the phase 3 PERSIST-2 study of PAC *vs* BAT (including RUX) in pts with MF and BL thrombocytopenia, PAC was significantly more effective in terms of spleen volume reduction (SVR; P=0.001) and appeared to have a better benefit/risk profile *vs* BAT.

Aims: This analysis examines outcomes for pts with MF treated with RUX in the phase 3 PERSIST-2 study.

Methods: Pts with MF and BL platelet count ≤100,000/µL were randomized (N=311) 1:1:1 to PAC 400mg once-daily (QD), PAC 200mg twice-daily (BID), or BAT. BAT included any physician-selected treatments for MF, as well as symptom-directed treatment, or no treatment. The co-primary endpoints were the rates of pts achieving ≥35% SVR (by MRI/CT) and ≥50% reduction in total symptom score (TSS; MPN-SAF TSS 2.0) at week 24. Efficacy analyses used the intent-to-treat efficacy (ITT-E) population, which included all pts with randomization date allowing them to contribute data for a week 24 endpoint. Crossover from BAT to PAC was allowed after week 24 or splenic progression.

Results: RUX was the most commonly received active BAT; 44 (45%) BAT pts received RUX (Figure) and 32 (33%) received only RUX. Of the 44 pts who received RUX on study, 17 (39%) had BL platelet counts <50,000/µL and would not have been candidates for RUX by approved indication (or study protocol). Around half of PAC (46%) and BAT pts (51%) had received prior RUX, including 32/44 (73%) pts treated with RUX on study. One (3%) and 6 (19%) RUX pts (n=32 in ITT-E population) achieved SVR ≥35% and TSS reduction ≥50% at week 24, respectively, *vs* 11 (15%) and 13 (17%) PAC QD and 16 (22%) and 24 (32%) PAC BID pts. For PAC pts with prior RUX, SVR and TSS endpoints were achieved in 6% and 10% with QD, and 13% and 32% with BID, *vs* 20% and 23% with QD, and 28% and 33% with BID for PAC pts without prior RUX. Grade 3/4 adverse events (AEs) were reported in 76%, 70%, and 45% of PAC QD, PAC BID, and RUX pts, most commonly (≥9% in any arm) thrombocytopenia (31%, 32%), anemia (27%, 22%), and neutropenia (9%, 7%) with PAC QD and BID, respectively, and thrombocytopenia (16%) anemia (9%), and neutropenia (2%) with RUX. Dose reductions due to AEs occurred in 20%, 12%, and 11% of pts treated with PAC QD, PAC BID, and RUX, respectively, though the majority of RUX-treated pts began with 5mg dosing (Figure). Discontinuations due to AEs occurred in 19%, 15%, and 16% of pts treated with PAC QD, PAC BID, and RUX, respectively. Half (22/44) of RUX-treated pts crossed over to PAC treatment, at a median of 26.1 (95% CI 25.3-27.3) weeks. Of those 22, 19 pts remained on PAC treatment at the time of data cut-off, 7 for ≥24 weeks of PAC treatment (Figure 1).

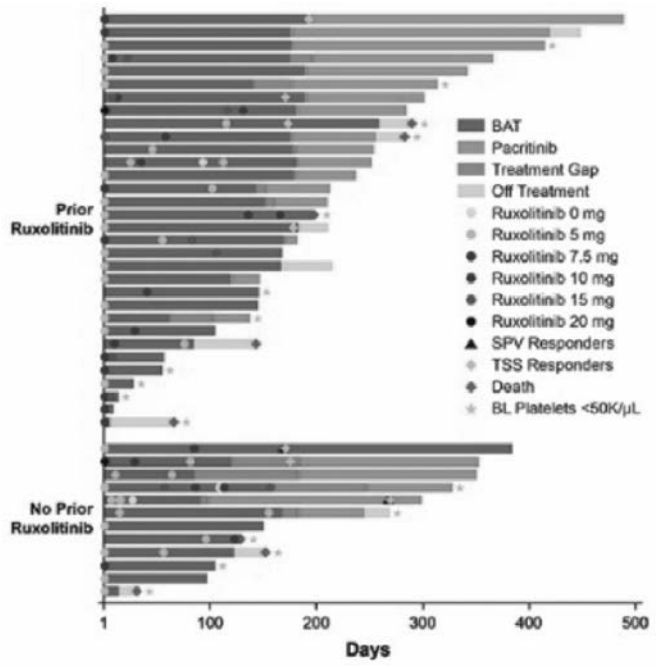

Figure 1.

Summary/Conclusions: In the phase 3 PERSIST-2 study of PAC *vs* BAT in pts with MF and BL thrombocytopenia, although 19% of RUX-treated pts achieved a 50% reduction in TSS, RUX-treated pts rarely achieved SVR ≥35% at week 24. Rates of grade 3/4 AEs were higher with PAC *vs* RUX treatment, though the majority of RUX-treated pts began with 5mg dosing. Rates of dose reductions and discontinuations due to AEs with PAC BID and RUX were similar. Following crossover to PAC in 22 RUX-treated pts, 19 remained on treatment at the time of data cut-off.

Ltd, Hyderabad, India, [12]Azienda Ospedaliera Bianchi-Melacrino'-Morelli, Reggio Calabria, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that has led to reductions in splenomegaly and symptoms in patients (pts) with MF. Although few studies have assessed RUX in elderly pts, a recent analysis including 100 pts >75 y showed that RUX was safe and effective in these pts, with safety and efficacy outcomes similar to those in younger pts (Latagliata *et al. Blood*. 2016;128:4251). JUMP, a large (N=2233), phase 3b, expanded-access trial assessed safety and efficacy of RUX in pts with no access to RUX outside a clinical trial and included a cohort of pts ≥75 y.

Aims: To assess the safety and efficacy of RUX in pts aged ≥75 y.

Methods: Pts with high- or Int-2–MF, or Int-1–risk pts with a palpable (≥5 cm) spleen, were eligible. RUX starting doses were based on baseline platelet (PLT) counts (5mg bid [≥50 to <100×10^9/L], 15mg bid [100 to 200×10^9/L], or 20mg bid [>200×10^9/L]). Pts were ≥18 y; there was no maximum age limit. The primary endpoint was safety and tolerability of RUX. Secondary endpoints included changes in spleen length and symptoms.

Results: This analysis includes 416 pts (primary MF, 66%) who were ≥75 y and started treatment ≥1 y before data cutoff (01 Jan 2016). Baseline characteristics (median) were age, 78 y (range, 75-89 y); male, 57%; spleen length, 10 cm (0-35 cm); blast count ≥1%, 30.3%; hemoglobin, 101 g/L (<100 g/L, 46.9%); PLT count, 249×10^9/L (<100×10^9/L, 6.3%); ECOG PS <2, 84.9%. At data cutoff, more than half of pts remained on treatment or completed treatment per protocol (52.6%). As expected, a greater proportion of elderly pts discontinued RUX due to adverse events (AEs; 23.6%) or death (8.7%) than pts in the overall study (17.7% and 4.1%, respectively). Overall, 72.4% of pts had dose modifications (AEs, 58.4%), and 33.9% had an interruption (AEs, 31.5%). Safety of RUX in elderly pts was consistent with that in the overall population. Median exposure was 11 mo; mean average daily dose was 26.8mg (SD, 10.6). The most common hematologic grade 3/4 AEs were anemia (43.8%; overall, 34.1%) and thrombocytopenia (22.1%; overall, 16.3%). AEs (all grade [grade 3/4]) in >10% of pts included asthenia (18.3% [2.6%]), pyrexia (18.0% [2.6%]), dyspnea (14.4% [4.3%]), diarrhea (13.5% [1.9%]), fatigue (11.8% [2.4%]), peripheral edema (10.8% [0.2%]), and pneumonia (10.1% [7.2%]). Infections in >5% of pts included pneumonia (10.1%), urinary tract infection (7.0%), and bronchitis (5.1%). Herpes zoster occurred in 3.9% of pts. At wk 24, 56.4% (124/220) of pts had a ≥50% reduction from baseline in spleen length (overall, 56.6%), and 19.1% (42/220) had 25%-50% reductions (overall, 23.3%); rates were similar at wk 48 (54.6% [65/119] and 19.3% [23/119]; overall, 61.6% and 18.9%). Most pts (64.2%) achieved a ≥50% reduction at any time (**Figure 1**), similar to the overall population (70.2%). Pts also experienced significant improvements in symptoms. From wk 4 to 48, 42%-48% and 50%-57% of pts achieved a clinically meaningful response on the FACT-Lym TS and FACIT-Fatigue, respectively.

Figure. Best Percent Change From Baseline in Palpable Spleen Length at Any Time by Week 72

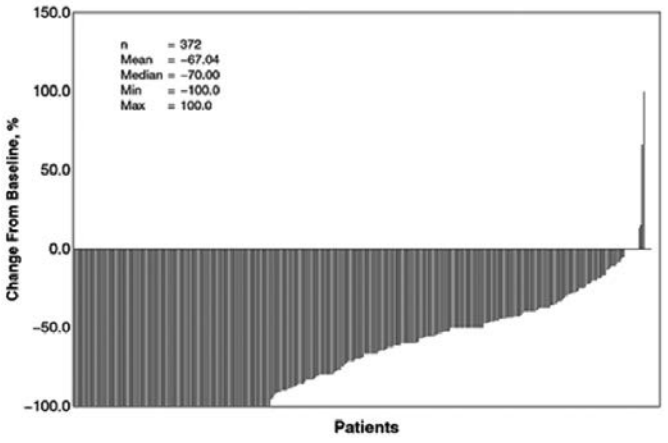

Figure 1.

Summary/Conclusions: This analysis included the largest cohort of elderly pts with MF treated with RUX to date. Consistent with the study by Latagliata et al, RUX was safe and effective in pts ≥75 y, with pts achieving reductions in splenomegaly and symptoms similar to those in the overall population, with comparable rates of AEs. Additionally, findings from our study were consistent with those of the COMFORT studies, which included few pts ≥75 y. Overall, our study provides further evidence that RUX is safe and effective in elderly pts with MF.

P703

PROGNOSTIC RISK MODELS FOR TRANSPLANT DECISION-MAKING IN MYELOFIBROSIS

Background: Accurate disease risk stratification is crucial for transplant decision-making in myelofibrosis (MF). Although several prognostic models are available, it is unknown if they are equivalent in the way they distribute patients into risk groups and in their discriminatory power to predict survival.
Aims: We have compared the performance of the International Prognostic Scoring System (IPSS), dynamic IPSS (DIPSS), DIPSS-plus, and Rumi's score in a series of 544 MF patients aged 70 years or younger at time of diagnosis.
Methods: The Spanish Registry of Myelofibrosis is a nationwide, longitudinal registry contributed by centers associated to the *Grupo Español de Enfermedades Mieloproliferativas Filadelfia negativas* (GEMFIN). From January 2000 to January 2016, a total of 544 adult patients aged ≤ 70 years with primary MF (n=335) or secondary MF (n=209) had been included in the registry. Cases of the prefibrotic form of MF were not considered. Comparison of the relative power of each prognostic model to discriminate levels of risk was estimated by means of the Harrell's concordance index (C-index) and the R^2explained variation. All the statistical analyses were performed with IBM SPSS 22.0 and Stata 11.
Results: At the study closing date, median follow-up from diagnosis of MF was 3.35 years, 177 patients (33%) had died, and the remaining were censored alive. Sixty-nine patients (13%) had been submitted to allogeneic stem cell transplantation, after a median time of 20 months from MF diagnosis. The median projected survival of the overall series was 9.46 years (95% confidence interval: 7.44-10.59). Median survival was not reached for the low risk category of all classifications (and Rumi's very low risk category). The projected survival for patients in the intermediate-1 group (intermediate in the Rumi's score) and in the high risk group (very high risk in the Rumi's score) was comparable in the four models. By contrast, the Rumi's high risk group had a projected median survival of 9.2 years, whereas that of the intermediate-2 categories by the IPSS, DIPSS, and DIPSS-plus models was 6.6 years, 5.6 years, and 6.5 years, respectively. The number of patients in the intermediate-2 and high risk categories was smaller in the DIPSS than in the IPSS or the DIPSS-plus. Overall, the Rumi's score yielded the highest power to discriminate between risk categories as measured by the concordance index and the R^2 explained variation. However, the IPSS and DIPSS-plus were the best models to discriminate between the intermediate-1 and intermediate-2 risk categories, which is the critical cut-off point for patient selection to transplant.
Summary/Conclusions: In our contemporary series of MF patients only the highest risk categories of the current prognostication systems have a median survival below the 5-year threshold recommended for considering transplantation. Patient selection for transplant is quite dependent on which prognostication model is used for disease risk stratification.

P704

LEUKEMIC TRANSFORMATION AND SECOND CANCERS IN 3649 HIGH RISK ET PATIENTS IN THE EXELS STUDY

G. Birgegård[1,*], Y. Folkvaljon[2], H. Garmo[2], L. Holmberg[3,4], C. Besses[5], M. Griesshammer[6], L. Gugliotta[7], J. Wu[8], H. Achenbach[9], J.-J. Kiladjian[10], C. N. Harrison[11]
[1]Department of Haematology, Uppsala University, [2]Regional Cancer Centre, Uppsala University Hospital, Uppsala, Sweden, [3]King's College London, Faculty of Life Sciences and Medicine, London, United Kingdom, [4]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden, [5]Department of Haematology, Hospital del Mar-IMIM, Barcelona, Spain, [6]Hematology and Oncology, Johannes Wesling Medical Center, Minden, Germany, [7]Department of Haematology, St Orsola-Malpighi Hospital, Bologna, Italy, [8]Global Biometrics, Shire Pharmaceuticals, Lexington, United States, [9]Research & Development, Shire GmbH, Zug, Switzerland, [10]APHP, Saint-Louis Hospital, Clinical Investigations Center, Paris, France, [11]Department of Haematology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: A common therapy for essential thrombocythemia (ET), hydroxycarbamide (HC), has mutagenic properties and there is potential for leukemogenicity and secondary cancers with this agent. In the EXELS study, we reported higher event rates for acute myeloid leukemia (AML) and other malignancies in HC-treated patients compared with those treated with anagrelide (ANA). However, there were large age differences between groups. Here, we account for age difference by estimating standard incidence ratios (SIRs) using country-specific cancer registration data.
Aims: To assess the risk of AML and non-hematological malignancies in patients treated with HC or ANA in the EXELS study.
Methods: Previous exposure to ANA and HC was based on patient history. SIRs were calculated using background rates retrieved from Cancer Incidence in Five Continents (CI5). Risk of AML after study enrolment was estimated by cumulative incidence. Minimum exposure time of 180 days was used to account for disease progression as a confounding factor. Informed consent was obtained before the start of the study.
Results: Overall, 3460 patients were exposed to HC, ANA or both at registration; 481 patients had ANA treatment, 2305 had HC treatment and 674 had been exposed to both drugs. The median age in ANA patients was 51 years, and 71 years in HC patients. One hundred and seventy four cases of non-hematologic cancer, including 35 cases of skin cancer, were recorded. SIRs for all malignancies were close to 1 for all treatment groups, indicating similar risks to the background population. For all skin cancers, including melanoma, the SIR for patients with HC treatment was higher than expected for the normal population and patients on ANA (1.15 *vs* 0.45). When melanoma was excluded, the figures changed only marginally. However, due to the low number of events, the CIs were wide, and no statistically significant difference was found between treatments. Sixty seven AML cases were reported; 39 AML cases were found in the HC group (person-years 8970, SIR 39.7), with another 20 AML cases in the group who switched from HC to ANA (person-years 2934, SIR 91.5). The risk ratio for AML developing in patients who switched from HC more than doubled (RR 2.30-2.52), irrespective of minimum exposure time. In contrast, no AML case was observed in the ANA-only group (person-years 1905, SIR 0) and there were only 3 AML cases in the group who switched from ANA to HC (person-years 802, SIR 68.5). Since the number of AML cases in the ANA group was 0, no statistical comparison could be made. Five AML cases were excluded from analysis since there was uncertainty about which drug was used first.

Table 1.

Table 1. Standardized incidence ratios (SIRs) with 95% confidence intervals (CIs). A minimum time of 180 days on a drug is required to be classified as exposed

	Observed	Expected	Person-years	SIR
Acute myeloid leukemia (C92.0)*				
ET without HC/ANA	0	0.08	331	0.00
ET with HC	39	0.98	8970	39.7
ET with ANA	0	0.08	1905	0.00
ET with HC and then ANA	20	0.22	2934	91.5
ET with ANA and then HC	3	0.04	802	68.5
Skin cancer (C43-C44)				
ET without HC/ANA	0	0.66	331	0.00
ET with HC	28	24.3	8967	1.15
ET with ANA	1	2.21	1905	0.45
ET with HC and then ANA	5	5.38	2941	0.93
ET with ANA and then HC	1	1.05	802	0.95
Skin cancer, other (C44)				
ET without HC/ANA	0	0.56	331	0.00
ET with HC	24	21.2	8968	1.13
ET with ANA	1	1.76	1905	0.57
ET with HC and then ANA	4	4.51	2941	0.89
ET with ANA and then HC	0	0.83	802	0.00
All cancers (C00-C96)				
ET without HC/ANA	0	4.64	331	0.00
ET with HC	159	166	8937	0.96
ET with ANA	8	15.4	1899	0.52
ET with HC and then ANA	53	39.1	2906	1.36
ET with ANA and then HC	7	8.31	795	0.84

ANA: anagrelide; HC: hydroxycarbamide. *Five AML patients with exposure to both HC and ANA not included in the analysis, since there is uncertainty about which drug was given first.

Summary/Conclusions: ET patients have a substantially increased risk for AML development; the SIR for AML was 40-fold higher than expected with HC exposure. In patients who switched from HC to ANA the SIR was approximately 90-fold higher, with 20 AML cases observed *versus* the expected 0.22 cases. The number of AML cases was much lower (n=3) in patients who switched from ANA to HC. It has been proposed that exposure of ET patients failing HC therapy to a second potentially leukemogenic agent should be avoided; yet these data suggest that even after switching to a non-leukemogenic agent, HC-treated patients still have an over 90-fold increased risk of AML. Our data reinforces concerns of a leukemogenic effect of HC, with a markedly higher risk in patients failing HC and switching to another drug, even if that drug is ANA. The caution advocated in the use of HC seems well advised.

Background: Infectious complications represent one of most frequent cause of morbidity and mortality in Myelofibrosis (MF), the most severe of myeloproliferative neoplasms. Ruxolitinib (RUX), the first approved JAK1/2 inhibitor, significantly ameliorates disease-related splenomegaly and constitutional symptoms. Prospective controlled studies observed a high rate of infectious complications including opportunistic and unusual infections, probably due to its immune-suppressant activity. However, risk factors for infections in MF patients (pts) treated with RUX are still to be investigated.
Aims: To evaluate characteristics, incidence and risk factors for infections in RUX-exposed MF pts.
Methods: Clinical and laboratory data of MF pts treated with RUX were retrospectively collected from the database of 21 Italian Hematology Centers. Infections were defined according to the CTCAE.

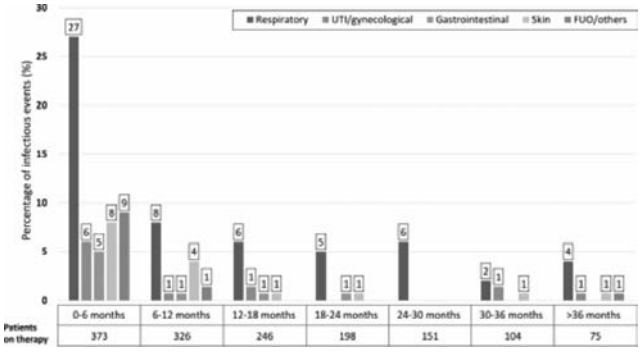

Figure 1.

Results: Overall, 373 pts received RUX between June 2011 and June 2016. At RUX start the clinical features were (median): age 68 years (27-89), ≥65y, 62%; male, 57%; Hb, 10.8g/dL (7-16.7); Hb <10g/dL, 40%; PLT, 246×10^9/L (33-1887); PLT <100×10^9/L, 10%; spleen enlargement, 97%; spleen length ≥10cm, 66%; constitutional symptoms, 52%. International Prognostic Score System (IPSS) was intermediate-1 (15%), intermediate-2 (46%), high (39%). *JAK2*^{V617F} mutation was detected in 255 out of 313 evaluated pts (81%). Karyotype was unfavorable in 15 out of 203 evaluable pts (7%). Previous infectious complications were recorded in 31 pts (8%). After a median RUX exposure of 20 months (range, 1-56), 101 pts (27%) experienced 129 infectious events ([3]grade 3, 33%), for an incidence rate of 14.9 cases for 100 pts/year. The rate of infections tended to decrease over time: 54% occurred within 6 months of therapy, 15% between 6 and 12 months, 9% between 12 and 18 months (p<0.0001). Respiratory tract infections were more frequently observed (73 events, 57%). Cutaneous, urinary tract and gastrointestinal infectious events were diagnosed in 15%, 10% and 7% of cases, respectively. In 14 cases fever of unknown origin was recorded (**Figure 1**). Etiological agents were isolated in 14 cases (11%): bacteria in 9 cases (gram+ 56%, gram- 22%, *C. difficile* diarrhea 22%) and fungi in 2 cases (pulmonary aspergillosis and oesophageal candidiasis); *Mycobacterium tuberculosis* was isolated in 3 cases. Herpes-virus reactivations occurred in 12 cases (9%). No patients reactivated hepatitis B virus. At last follow-up, 88 pts (24%) have died, in 10 cases (11%) due to infectious complication. Among baseline features, age≥65 years at RUX start (p<0.0001), previous infection (p=0.001), primary *vs* secondary MF (p=0.021) and high IPSS (p=0.029) significantly correlated with higher infectious risk. Notably, no differences were observed according presence of large (≥10cm) splenomegaly, higher (>20) total symptoms score, presence of cytopenias, Charlson comorbidity index (>2) and body mass index (<21 and >30). In multivariate analysis, PMF diagnosis (HR 1.6 CI95% 1.07-2.5), age≥65 years (HR 2.1 CI95% 1.3-3.3) and previous infection (HR 3 CI95% 1.7-5.4%) confirmed their negative prognostic association. Interestingly, RUX dosage, spleen response and hematological toxicities during treatment were not associated with infectious risk.
Summary/Conclusions: Infections occurred in around one-third of RUX-treated pts; the rate of infections tended to decrease over time, and were fatal in 11% of the cases. Advanced age, a previous infectious event and diagnosis of PMF seem to be the main contributors to infectious risk.

P706

TREATMENT AND MANAGEMENT OF PATIENTS WITH MPNS-FINDINGS FROM THE INTERNATIONAL MPN LANDMARK SURVEY

Background: Patient (pts) with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. Pts are managed with watchful waiting or therapy, including aspirin, hydroxyurea (HU), and other drugs. The international MPN LANDMARK survey evaluated the patient-reported impact of MPNs in pts in 6 countries and identified current management strategies in these pts.
Aims: To analyze treatment strategies used by physicians and pts to manage MPNs.
Methods: This cross-sectional, internet-based survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK and was administered to pts with MPNs and to physicians treating pts with MPNs. Pts and physicians were recruited independently. We describe disease-management strategies in these pts.

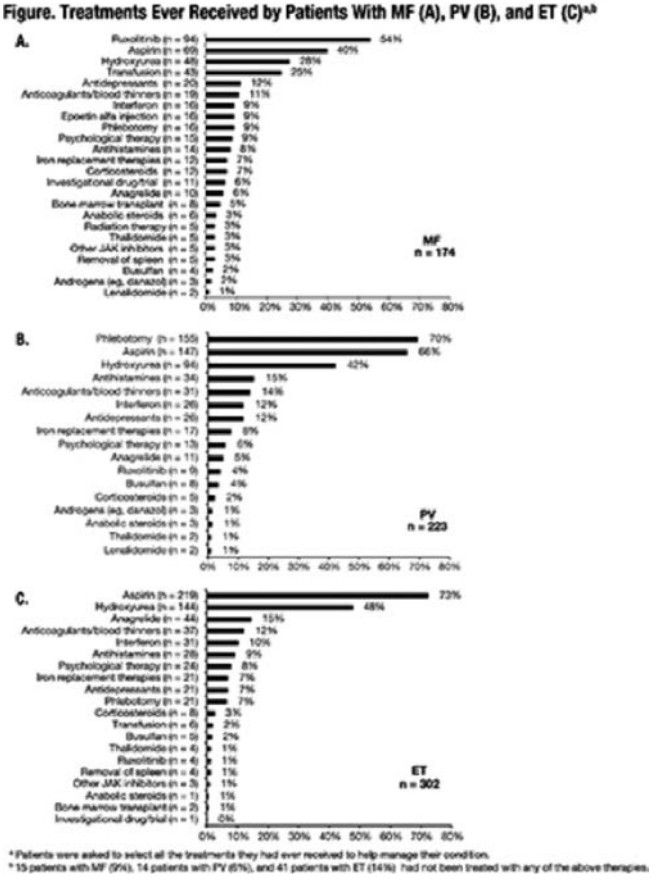

Figure 1.

Results: Overall, 699 pts (MF, n=223; PV, n=174; ET, n=302) and 219 physicians completed the survey. In line with treatment guidelines, main therapies used by pts were ruxolitinib (54%), aspirin (40%), and HU (28%) in MF; phlebotomy (PLB; 70%), aspirin (66%) and HU (42%) in PV; and aspirin (73%), HU (48%), and anagrelide (15%) in ET (**Figure 1.**). Most physicians reported prescribing the following: ruxolitinib (76%), transfusion (54%), and HU (53%) in MF; aspirin (79%), HU (77%) and PLB (67%) in PV; and aspirin (80%), HU (67%), and anagrelide (52%) in ET. Many physicians (51% MF, 47% PV, 49%

ET) chose watchful waiting to manage >25% of their pts at diagnosis; 22% of untreated pts had moderate to high (quartiles 3-4) overall symptom burden. Physicians primarily recommended treatment for pts experiencing severe symptoms (72% MF, 68% PV, 72% ET) or symptomatic splenomegaly (71% MF, 61% PV, 39% ET). PLB was mainly used to treat pts with PV. Of those who received PLB (n=155), 71% were very or somewhat satisfied; 25% were very or somewhat dissatisfied and felt that PLBs had a negative impact on their QOL. Similarly, 37% of physicians felt that PLB had a negative impact on pt QOL; PLB alone was insufficient for disease control in 38% of pts. Pts stopped PLB because physician deemed it no longer necessary (62%), pts felt worse after treatment (10%), and visit frequency was inconvenient (8%). Physician-reported reasons for stopping PLB were that visit frequency was inconvenient (38%), pts felt worse after treatment (35%), and lack of intravenous access (33%). HU use was assessed in pts with PV or ET. Of those who received HU (PV, n=95; ET, n=145), 78% and 74%, respectively, continued to receive HU; 19% and 22% were dissatisfied with HU therapy. Main reasons for stopping HU were lack of efficacy (29% PV, 13% ET) and toxicity (19% PV, 27% ET). Overall, 78% of physicians reported that up to 25% of their pts showed inadequate efficacy or intolerance of HU. Main measures of treatment success among pts were physician feedback (73% MF, 75% PV, 75% ET) and blood counts (72% MF, 67% PV, 74% ET). Lack of efficacy, side effects, and disease progression were key reasons for changing therapies.

Summary/Conclusions: Many pts with MPNs are managed with watchful waiting at diagnosis. Although most of these pts have a low symptom burden, 22% have a moderate to high burden, highlighting the need for proactive and standardized symptom assessments at diagnosis and over the course of treatment. Interestingly, a proportion of physicians and pts felt that phlebotomy had a high negative impact on pt QOL. Overall, pts consider physician feedback and blood counts to be important indicators of treatment success.

P707

SUCCESSFUL LONG-TERM MAINTENANCE OF PV PATIENTS WITH A MONTHLY SCHEDULE OF ROPEGINTERFERON ALFA-2B-AN UPDATE FROM THE PEGINVERA STUDY

Internal Medicine V, Haematology & Oncology, Innsbruck Medical University, Innsbruck, Austria, [6]Department of Hematology, Oncology and Rheumatology, Center of Integrated Oncology Cologne Bonn, University Hospital of Bonn, Bonn, Germany, [7]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [8]Hematology and Hemostaseology, Medical University Vienna, [9]Sozialmedizinisches Zentrum Ost - Donauspital, Vienna, [10]IIIrd Medical Department, Salzburg Cancer Research Institute, Paracelsus Medical University, Salzburg, Austria, [11]Aprova CRO, Brno, Czech Republic

Background: Ropeginterferon alfa-2b is a novel long-acting monopegylated interferon alpha (IFNa) with Orphan designation in Europe and the U.S. Reduced dosing frequencies and favorable tolerability accompanied by robust clinical responses in patients with polycythemia vera (PV) have been reported over the first few years of treatment. Successful long-term, potentially life-long maintenance with high rates of adherence, compliance and treatment outcome remain important goals to be elucidated.

Aims: PEGINVERA phase I/II (NCT: 2010-018768-18), is a prospective, open-label, multicenter study investigating efficacy and safety of ropeginterferon alfa-2b in long-term treatment of patients with confirmed diagnosis of PV, pre-treated or naïve to cytoreductive therapy.

Methods: All patients responding well to the initial bi-weekly administration schedule and participating in the study for longer than one year, had the option to switch to a "once every 4 weeks"-schedule. The 2-week regimen (defined as the time period when all criteria for switching were fulfilled but the patient continued the 2-week regimen) was compared to the 4-week regimen (for a duration of 6 months after switch). The present analysis was focused on maintenance of efficacy.

Results: Data from the last available analysis include 29 patients remaining on study with a median treatment duration of 213 weeks. All 29 patients have completed at least 2 years of treatment (5 patients are in the 3rd year, 7 in the 4th year, 10 in the 5th year and 7 in the 6th year of treatment). Baseline characteristics of the study cohort during short-term treatment and two year safety and efficacy follow-up data were already presented earlier (Gisslinger *et al.* 2015). All of the 29 patients were switched to dosing once every 4 weeks. Median treatment duration at time of switch was 104 weeks (Q1-Q3: 69-124 weeks). All 29 patients remained on the 4-week schedule with a median observation duration of further approx. 2 years for this analysis, reflecting the excellent safety and tolerability profile of ropeginterferon alfa-2b in this setting. The percentage of patients maintaining their best haematological response according to ELN before (i.e. after median 104 weeks of treatment) and 6 months after switching to the 4-week regimen was consistent at 51.7%. Further, need for phlebotomy during the 6 months after switching did not increase (consistent 7/29 patients). Changes in haematological parameters and spleen size were minimal and without clinical relevance. Similarly, the percentages of patients maintaining their best molecular response were 62.1% and 58.6%, respectively (non-significant). Importantly, the majority of patients on ropeginterferon alfa-2b long-term treatment, developed a sustained reduction of mutant JAK2 allele burden to below 10%, a feature that can only be achieved by IFNa based therapies.

Summary/Conclusions: In summary, all patients remaining on ropeginterferon alfa-2b after a median of 2 years of initial treatment were successfully switched to a more convenient monthly long-term maintenance schedule, thereafter no patients discontinued, and all patients could be maintained on this schedule for currently another 2 years (trial still ongoing). These data underscore the expected long-term efficacy with regard to haematological, clinical and molecular parameters and the excellent safety/tolerability of ropeginterferon alfa-2b. Long-term maintenance treatment of PV patients using ropeginterferon-alfa 2b monthly is feasible, efficacious and well tolerable. Continuous patient-individual adaption of dosing regimen, including dose and dosing schedule, is recommended.

P708

NO IMPROVEMENT IN SURVIVAL OVER TIME FOR PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASM PATIENTS WHO TRANSFORM TO ACCELERATED OR BLAST PHASE

C. Mcnamara[1,*], J. Kennedy [1], T. Panzarella[2], G. Daher-Reyes[1], R. Alblooshi[1], J. Ramanna[1], A. Arruda[1], J. Ho[1], N. Siddiq[1], J. Claudio[1], R. Devlin[1], T. Stockley[3], M. Sukhai[3], M. Thomas[3], S. Chan [1], D. Maze[1], A. Schimmer[1], A. Schuh[1], H. Sibai[1], K. Yee[1], S. Kamel-Reid[3], M. Minden[1], V. Gupta[1]
[1]Department of Medical Oncology and Hematology, [2]Department of Biostatistics, [3]Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, Toronto, Canada

Background: The outcome of patients with Philadelphia negative myeloproliferative neoplasms (MPN) who transform to acute leukemia is abysmal. There have been no advances in targeted therapy for this cohort of patients or individualized treatment based on genomic information. Furthermore, no large studies have investigated the impact of molecular profiling on clinical outcome in patients with accelerated or blast phase of MPN.

Aims: To describe the clinical outcomes of patients with MPN who transform to accelerated or blast phase and evaluate the impact of genomic alterations on outcomes.

Methods: Eligibility criteria included: Prior diagnosis of Philadelphia negative MPN according to WHO 2008 criteria; evidence of transformation to accelerated (10-19% blasts in peripheral blood or bone marrow) or blast phase (≥20% blasts) and seen at Princess Margaret Cancer Center between January 1998 and February 2017. The primary endpoint was overall survival (OS): defined as the time from transformation to death or last follow-up. Secondary endpoints included survival based on curative *versus* non-curative approach and treatment over time. In addition the impact of mutations will be correlated with clinical outcomes and survival.

Figure 1: OS for patients treated from 1998 until June 2011 (arm a) and patients treated from July 2011 until 2017 (arm b)

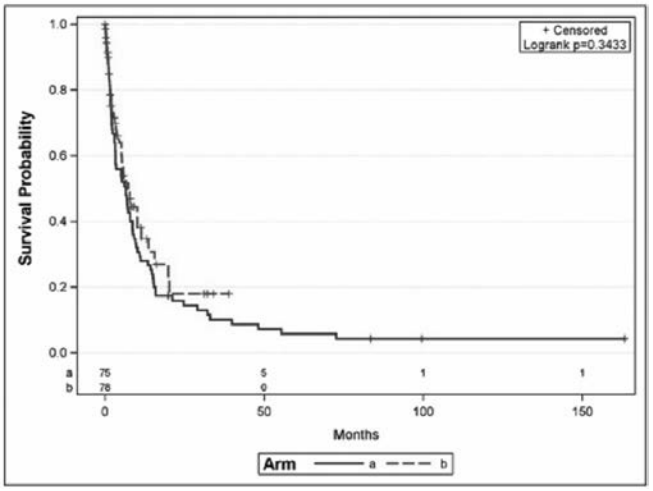

Figure 1.

Results: One hundred and eighty-seven patients who transformed to accelerated or blast phase with a prior diagnosis of MPN were identified at our insti-

tution. Twenty-nine patients were excluded: 17 for myelodysplastic/myeloproliferative overlap (MDS/MPN), six for insufficient information, five for not meeting criteria for accelerated or blast phase and one patient for a diagnosis of systemic mastocytosis. Of the 158 patients included in the study, the median age at the time of MPN diagnosis and leukemic transformation was 59 and 67 years respectively. Prior MPN diagnosis was: polycythemia vera (PV; n=25, 16%), essential thrombocythemia (ET; n=21, 13%), primary myelofibrosis (n=50, 32%), post ET myelofibrosis (PET MF; n=27, 17%), post PV myelofibrosis (PPV MF; n=24, 15%) and MPN-unclassifiable (n=11, 7%). One hundred and forty-two (90%) patients met the criteria for acute myeloid leukemia, thirteen (8%) had accelerated phase and 3 (2%) patients were diagnosed with myeloid sarcoma. Sixty-four (41%) patients were treated with curative intent including 27 (42%) patients who proceeded to hematopoietic cell transplantation, while 94 (59%) received non curative approach including low dose chemotherapy, hypomethylating agent, clinical trial or best supportive care. The median OS for the entire cohort was 6.5 months (95% CI: 5.06-8.01). In patients treated with curative intent median OS was 8.8 *versus* 3.2 months (p=0.003) for patients with non-curative intent. There was no difference in OS between historical controls treated between 1998 and 2011 when compared to a more recent cohort of patients (6.5 *vs* 7.3, p=0.34; see Figure 1). In 105 (67%) patients, NGS molecular profiling of 54 genes (39 hotspot region; 15 complete coding region coverage) was performed on peripheral blood or bone marrow samples using the TruSight Myeloid Sequencing Panel. Mutational data will be correlated with clinical outcomes and will be presented at the EHA annual conference (profiling completed, analysis ongoing).

Summary/Conclusions: Despite advances in systemic therapies and supportive care, there has been no significant improvement in survival for MPN patients who transform to accelerated or blast phase, confirming that current treatment approaches are ineffective. Results of molecular profiling may provide valuable insights and clues as to how to develop an individualized treatment approach for this cohort of patients.

Other Non-malignant hematopoietic disorders

P709

MASITINIB FOR TREATMENT OF SEVERELY SYMPTOMATIC INDOLENT SYSTEMIC MASTOCYTOSIS: ADDITIONAL EFFICACY ANALYSES FROM THE RANDOMIZED, PLACEBO-CONTROLLED, PHASE 3 STUDY

Background: Masitinib, a selective oral tyrosine kinase inhibitor targeting wild-type KIT, LYN and FYN, was the first drug to demonstrate efficacy in a phase 3 setting (study AB06006) for treatment of patients with severe indolent systemic mastocytosis (ISM) who are unresponsive to existing, optimal symptomatic treatments. In *The Lancet* (Feb 11;389(10069):612-620), Lortholary and colleagues reported a significant and clinically meaningful treatment benefit for masitinib (6mg/kg/day over 24-weeks) *versus* placebo, with primary analysis based on cumulative response (≥75% improvement from baseline, timeframe weeks 8-24, comprising 5 visits at 4-week intervals) in at least one of four severe baseline symptoms (pruritus, flushes, depression, or fatigue) using repeated measures methodology for rare diseases (i.e. a longitudinal analysis with respect to symptoms as opposed to patient response rate at a single point in time). Eligible patients were aged 18–75 years and had ISM according to inclusion criteria that were slightly broader than the WHO classification.
Aims: To aide interpretation of this study's prospectively declared primary endpoint via comparison with additional efficacy analyses based on a cohort restricted to the WHO classification of ISM and more conventional patient-centric response endpoints.
Methods: Randomized, placebo-controlled, phase 3 study that included 135 severely symptomatic ISM patients, including the subvariant smoldering systemic mastocytosis (71 masitinib, 64 placebo), 80% of whom satisfied the WHO classification.
Results: Masitinib showed a significant improvement over placebo according to its pre-specified primary endpoint (mITT population), with a cumulative response of 18.7% *versus* 7.4%, respectively, odds ratio (OR) of 3.6 [95%CI 1.2-10.8], P=0.008 (with re-randomization). This outcome was confirmed in the WHO patient subgroup: 17.8% *versus* 8.0%, respectively, OR=3.25 [0.97-10.88], P=0.0317. Computing the primary analysis (mITT) according to cumulative response per patient (GEE model) was also positive: 26.7% *versus* 12.8%, respectively, OR=2.48 [1.16-5.31], P=0.0212; as was analysis according to individual patient response (Pearson chi-square): 40.3% *versus* 24.2%, respectively, P=0.0062. Response (per patient) on all severe baseline symptoms for at least one visit was: 16.4% *versus* 1.6%, respectively, P=0.0062. Finally, analysis of sustained response in all severe baseline symptoms over multiple visits was highly discriminatory between treatment-arms: for patients with 3 severe baseline symptoms masitinib generated a 12.5% response rate (≥75% improvement in each symptom) for 3 out of 5 visits, *versus* no response for placebo; and for patients with 2 severe baseline symptoms masitinib generated a response rate of 21.1%, 15.8% and 10.5% over at least 1, 2, and 3 visits, respectively, *versus* no response for placebo.
Summary/Conclusions: These post-hoc analyses confirm the clinical relevance, durability, and generalizability of the positive primary endpoint from study AB06006. Findings therefore support the conclusion that masitinib generates a significant therapeutic benefit in patients with severely symptomatic ISM who were unresponsive to optimal symptomatic treatments.

P710

THERAPY RESPONSE AND LONG-TERM OUTCOME OF 71 ADULT PATIENTS WITH HEMATOLOGICAL MALIGNANCY-ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A SINGLE INSTITUTION EXPERIENCE

M. Machaczka[1,2,*], K. Kosior[3], E. Pawłowicz[4], M. Wolan[2], M. Gajewski[5], M. Klimkowska[3]

[1]Hematology Center Karolinska, Karolinska University Hospital Huddinge, Stockholm, Sweden, [2]Medical Faculty, University of Rzeszow, Rzeszow, Poland, [3]Department of Clinical Pathology and Cytology, Karolinska University Hospital Huddinge, Stockholm, Sweden, [4]Medical University of Łódź, Łódź, [5]Medical University of Silesia, Katowice, Poland

Background: Hemophagocytic lymphohistiocytosis (HLH) is a devastating disorder of uncontrolled immune activation characterized by clinicopathological evidence of extreme inflammation. Hematological malignancy-associated HLH (hM-HLH) has the worst outcome in comparison with any other form of HLH. hM-HLH can occur as the first manifestation of an occult malignancy, before start or during the treatment of known malignancy, or as the sign of a malignancy relapse or transformation to the more aggressive disease form.
Aims: The aim of the present study was to analyze the response to HLH therapy and overall survival of adult patients with hM-HLH.
Methods: From 2008 and onwards, data on adult patients referred to the Hematology Center Karolinska with suspected HLH were prospectively collected. Review concerned records of 142 adults with suspected HLH, hospitalized between Jan 2009 and Dec 2016. Of those, 71 patients with hematological malignancy were diagnosed with HLH and included to the present study. Hematological malignancy was defined as a neoplasm of lymphoid or myeloid origin. In all studied patients, the diagnosis of HLH was based on the HLH-2004 criteria. Infection as a possible additional trigger of HLH was carefully studied in all our hM-HLH patients. EBV and CMV DNA were routinely examined in whole blood, using RT quantitative PCR; other viruses (*e.g.* adenovirus, HSV, VZV, HHV6, influenza) were studied based on indications. Blood and urine cultures were performed in order to reveal any bacterial or fungal infections. Tests for fungal antigens, tuberculosis, and parasites were also performed if indicated. HLH treatment categories have included proapoptotic chemotherapy (etoposide) and immunosuppressive drugs, targeting hyperactivated macrophages (etoposide, corticosteroids, IVIG) and T cells (corticosteroids, cyclosporine A).

Figure Overall survival rate in different subgroups of hM-HLH patients in respect to concomitant infection during chemotherapy (*n*=17) and other patients (*n*=54).

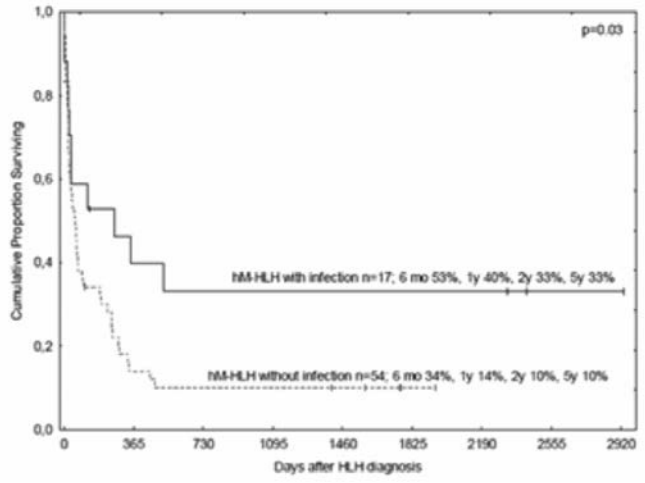

Figure 1.

Results: Seventy-one adults, aged 22–84 years, were diagnosed with aggressive hM-HLH during the 8-year period. Lymphoid malignancy was diagnosed in 42 patients and myeloid malignancy in 29 patients. Fifty-four (76%) patients developed HLH as a first manifestation of an unknown malignancy, during progressive disease, or malignancy relapse. The remaining 24% patients developed HLH during chemotherapy. In 14 patients, HLH therapy started before confirmation of HLH diagnosis, based on suspicion of HLH (mean 6.7±8.4 days; median 2 days; range 1-31 days). Seventeen patients started HLH therapy at the day of HLH diagnosis. In 36 patients HLH therapy started after confirmation of HLH diagnosis (mean 15.9±41.3 days; median 5 days; range 1–242 days). Forty of 71 (56%) patients with active HLH died, of which 20 had signs of progressive malignancy, 16 patients had generalized infection (bacterial - 12 patients, viral - 3 patients, fungal - 4 patients; some patients had more than one type of infection), and 2 patients experienced central nervous system bleeding. Thirty-one (44%) patients responded to HLH therapy and achieved remission of HLH. However, only 13 of 71 (18%) patients with hM-HLH were still alive after a median follow-up time of 50 months, despite the attempted treatment in 67 (94%) cases. The probability of overall survival (OS) from 6, 12, 24 and 60 months after HLH diagnosis were 39, 20, 15 and 15%, respectively. The patients who developed hM-HLH with concomitant infection during chemotherapy had significantly longer OS (p=0.03) compared to patients who had HLH solely attributed to malignancy (Figure 1).

Summary/Conclusions: HLH in the context of malignancy is still considered a challenge of adult hematology. hM-HLH is a highly lethal disorder in adults. The patients who develop hM-HLH with concomitant infection during chemotherapy show better survival than those who had HLH solely attributed to malignancy. Although poor outcome in some patients with M-HLH is related to malignancy progression, in some patients the lack of effective M-HLH therapy may further impede adequate treatment of malignancy.

P711

WHOLE-EXOME SEQUENCING IN CHILDREN WITH IMMUNE CYTOPENIA: THE APPLICABILITY AND CLINICAL IMPACT

M. Svatoň[1,*], V. Kanderová[1], P. Smíšek[2], M. Suková[2], L. Šrámková[2], J. Kayserová[3], J. Stuchlý[1], M. Žaliová[1], L. Dušátková[4], Š. Průhová[4], M. Vlčková[5], T. Freiberger[6], D. [1]CLIP - Childhood Leukemia Investigation Prague, Department of Paediatric Haematology and Oncology, [2]Department of Paediatric Haematology and Oncology, [3]Department of Immunology, [4]Department of Paediatrics, [5]Department of Biology and Medical Genetics, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, [6]Molecular Genetics Laboratory, Centre for Cardiovascular Surgery and Transplantation, Brno, [7]Department of Pediatrics, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, [8]Department of Pediatric Haematology, Masaryk University and University Hospital, Brno, [9]Department of Pediatrics, Masaryk Hospital, Ustí nad Labem, Czech Republic

Background: Next generation sequencing is rapidly becoming the main diagnostic tool for precise identification of gene defects in human diseases. Apart from the identification of novel causal genes and pathogenic variants, the main research goal for now is to assess the impact and strategy of whole exome sequencing (WES) use in routine clinical evaluation.
Aims: We aimed to evaluate the benefits and drawbacks of using WES as a diagnostic method in patients with chronic early-onset autoimmune hemolytic anaemia (AIHA), idiopathic thrombocytopenic purpura (ITP) and immune neutropenia, or their combination (Evans syndrome). Most of these patients presented with additional symptoms of immune dysregulation, *e.g.* common variable immunodeficiency (CVID), lymphoproliferation, autoimmune disorders (diabetes mellitus 1, thyreoiditis).
Methods: 30 patients (age 0-39) were evaluated after an examination by a clinical geneticist and signing an informed consent. Sequencing libraries were prepared from peripheral blood DNA using Agilent SureSelectXT Human All Exon V5/6+UTR kit and sequenced with the Illumina NextSeq 500 system with a mean coverage of at least 30x.
Results: In 10 patients (33%) we were able to find likely causative mutations. In 3 patients (siblings) we identified a novel variant leading to CTLA4 deficiency, another novel variant in CTLA4 was identified together with an additional pathogenic variant in TSC1, causing a mixed phenotype. The genetic diagnosis of CTLA4 deficiency allowed for the use of CTLA4 agonist (Abatacept) treatment in 1 patient that led to improvement of his symptoms and disease stabilisation. However, after 6 months, the patient had developed agranulocytosis that led to hematopoietic stem cell transplantation. In 1 patient we were able to identify a gain-of-function variant in STAT3 that was recently described in immune dysregulation. In 3 patients we observed variants in genes typically described in connection with antibody deficiency (TACI, CD40L, and IKBKG). In 1 patient with chronic AIHA and ITP we found a novel heterozygous variant in TERT gene related to dyskeratosis congenita. In 1 patient with multiple congenital abnormalities and Evans syndrome we discovered a heterozygous variant in KMT2D gene causing Kabuki syndrome. The remainder of our patients harboured variants that posed a diagnostic challenge. In 4 of these cases we identified variants in genes involved in the pathogenesis of immune dysregulation, which are observed at lower frequencies also in healthy people (CASP10, PIK3CD). 12 patients (36%) had either only one hit in the genes reported causal in autosomal recessive diseases (e. g. ITK, LRBA) or we have not yet found any relevant aberration. In 4 patients we were able to identify novel variants in genes related to immune dysregulation. However, these variants require extensive validation studies, using patients' primary cells or manipulating established in-vitro or animal models with gene editing techniques, in order to prove the causality.
Summary/Conclusions: WES is a highly useful method that helps to identify the genetic cause of the disease in approximately one third of patients and enables targeted therapy. While targeted sequencing can further reduce costs and make analysis more straightforward, gene panels are quickly becoming obsolete as new causal variants are discovered in the rapidly evolving field of primary immunodeficiencies. Because of the heterogeneity of genetic causes of immune cytopenias, we recommend to use WES over targeted gene panel sequencing.

Background: : Erythrocytoses are characterized by an elevated red cell mass. The most widely studied disease is Polycythemia Vera (PV), however, other types of erythrocytoses can be either inherited (Congenital Erythrocytosis-CE) or diagnosed in adult patients with no family history (Idiopathic Erythrocytosis-IE). CE/IE are not associated with myeloproliferation but they can be associated with severe thrombo-embolic or haemorrhagic events, pulmonary arterial hypertension and, rarely, tumours (hemangioblastoma, pheochromocytoma). The 8 genes identified so far as causing CE are involved (i) in the regulation of the hypoxia pathway, PHD2 (also called EGLN1), HIF-2A (EPAS1), VHL, (ii) in proliferation and differentiation of erythroid progenitors (EPOR), or (iii) in mature cell function, haemoglobins (HBB, HBA1, HBA2) or bisphosphoglyceratemutase (BPGM). However, in 80% of cases the cause remains unknown meaning that no proper diagnosis can be made, no prognosis or advice can be provided to CE/IE patients and their families, and no curative treatment exists
Aims: to (i) identify, (ii) collect and (iii) analyze the genomic abnormalities in patients suspected of CE
Methods: We created and developed a national network in France to analyze the genomic abnormalities in patients suspected of CE. The selection of patients was performed in order to exclude patients with Polycythemia Vera or obvious secondary erythrocytosis related to lung, cardiac or renal disorder. Next generation sequencing (NGS) has been used to analyse the presence of mutations in 28 genes (enlarged hypoxia pathway and other candidate genes).
Results: To date, samples from 140 patients have been recorded, among whom 46 have been tested using NGS approach. Variants in 14 (30%) patients [13 males and 1 female; median age 50 y. (12-71)] with unknown significance have been detected, including 4 in *PHD* genes, 5 in *HIF* genes, 4 in *LNK* genes (*SH2B3*) and 1 in *JAK2* gene. In patients with variants, a familial history of erythrocytosis was noted in 3. No independent thrombotic complication was reported in the 15 patients. In 2 patients (one with a *PHD2* and one with a *JAK2* variants), the erythropoietin was low, whereas for the others, the erythropoietin was normal. Of note, the median age of the patients was surprisingly high, suggesting that the diagnostic was not previously performed due to the absence of available tests. Functional studies were performed on *PHD2* variants: a significant decrease in the hydroxylase activity was noted for one variant, but not for the others. On the other hand, a decrease in the stability along time of the PHD2 protein was observed for two variants, underscoring the different mechanisms involved in the impairment of the PHD2 activity
Summary/Conclusions: NGS is a useful tool to explore mutations in CE, but identifies genetic variants in only 30% of patients with such disorder. Further exams including whole exome sequencing are planned to achieve a right diagnosis in the 70% remaining CE patients. *In vitro*, *in cellulo* and *in vivo* (including zebrafish model) functional studies are currently performed to validate the clinical relevance of the variants identified in the hypoxia pathway. They are compared to variants identified in the development of tumors in order to dissect the molecular mechanisms of this finely tuned pathway

CHARACTERIZATION OF CD34+ HEMATOPOIETIC PRECURSORS IN INDOLENT SYSTEMIC MASTOCYTOSIS AND THEIR POTENTIAL ROLE IN EARLY DISSEMINATION OF THE DISEASE

A. Mayado[1,*], C. Teodosio[2], N. Dasilva-Freire[1], M. Jara-Acevedo[3], A. García-Montero[1], I. Alvarez-Twose[4], L. Sánchez-Muñoz[4], A. Matito[4], C. Caldas[1], J. Muñoz-González[1], A. Henriques[4], J. Sánchez-Gallego[1], L. Escribano[1], A. Orfao[1]
[1]Cancer Research Centre (IBMCC, USAL-CSIC), Cytometry Service (NUCLEUS) and Department of Medicine, University of Salamanca, Salamanca, Spain; Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain, [2]Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands, [3]Sequencing DNA Service (NUCLEUS), University of Salamanca, Salamanca, [4]Instituto de Estudios de Mastocitosis de Castilla La Mancha (CLMast), Hospital Virgen del Valle, Toledo, Spain

Background: Recent studies show that most systemic mastocytosis (SM) patients, including indolent SM (ISM) with (ISMs+) and without skin lesions (ISMs-), carry the *KIT* D816V mutation in PB leukocytes.
Aims: To investigate the potenctial association between the degree of involvement of BM hematopoiesis by the *KIT* D816V mutation and the distribution of different maturation-associated compartments of bone marrow (BM) and peripheral blood (PB) CD34+ hematopoietic precursors (HPC) in ISM, and identify the specific PB cell compartments that carry this mutation.
Methods: The distribution of different maturation-associated of BM and PB CD34+ HPC from 64 newly-diagnosed (*KIT*-mutated) ISM patients and 14 healthy controls was analyzed by flow cytometry. In 18 patients distinct FACS-purified PB cell compartments were also investigated for the *KIT* mutation.
Results: ISM patients showed higher percentages of both BM and PB MC-committed CD34+ HPC *vs* controls, particularly among ISM cases with MC-restricted *KIT* mutation (ISM_{MC}); this was associated with progressive blockade of maturation of CD34+ HPC to neutrophil lineage from ISM_{MC} to multilineage *KIT*-mutated cases (ISM_{ML}). Regarding the frequency of *KIT*-mutated cases and cell populations in PB, variable patterns were observed, the percentage of *KIT*-mutated PB CD34+ HPC, eosinophils, neutrophils, monocytes and T-cells increasing from ISMs-$_{MC}$ and ISMs+$_{MC}$ to ISM_{ML} patients.
Summary/Conclusions: Positivity for the *KIT* D816V mutation in PB of ISM is usually associated with (early) involvement of circulating CD34+ HPC and multiple myeloid cell populations, *KIT*-mutated PB CD34+ HPC potencially contributing to disease dissemination already at very early stages.

P714

MONOALLELIC VARIANTS IN GENES RELATED TO FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: REPORT FROM THE ITALIAN REGISTRY

L. Vinas[1,2,*], M.L. Coniglio[1], D. Balasco[1], I. Fotzi [1], C. Favre [1], M. Aricò[3], E. Sieni[1]
[1]Hematology-Oncology Department, A. Meyer Children's University Hospital, Florence, Italy, [2]Immunology Department, Vall d'Hebron University Hospital, Barcelona, Spain, [3]Provincial health authority, Ragusa, Italy

Background: Hemophagocytic Lymphohistiocytosis (HLH) is a life-threatening disease of children and adults caused by an impaired cytotoxic function of NK and CTL cells leading to a potentially fatal hyperinflammatory condition. Biallelic mutations in genes involved in the cytotoxic pathway are responsible for the familial form of the disease (FHL). Monoallelic mutations in the FHL-related genes have been reported in association with HLH and other diseases but their role remains to be understood.
Aims: To describe clinical, functional and genetic features of patients referred to the Italian HLH Registry, harboring monoallelic mutations in FHL-related genes.
Methods: Patients with complete or partial HLH diagnostic criteria and monoallelic mutations in at least one of the FHL-related genes were selected from the Italian Registry. Clinical data were collected by specific forms. Perforin expression and NK-cell degranulation measured as CD107a expression were performed by flow-cytometry. Molecular analysis was performed by Sanger or Next Generation sequencing.
Results: Of the 600 patients reported to the Registry, 54 (9%) were found to have monoallelic mutations in FHL-related genes. Their median age was 5 years (quartiles: 1.7, 3, 13, 50 years). Twenty-nine of the 54 patients (54%) fulfilled at least 5 of the 8 diagnostic criteria: fever (n=49/52; 94%), splenomegaly (n=37/50, 74%), cytopenia (n=43/50, 86%), hypertriglyceridemia (n=28/47, 60%), hypofibrinogenemia (n=1/46, 0.02%), hyperferritinemia (n=47/50, 94%; quartiles: 1.454, 7.937, 17.050, 140.000 ng/ml), hemophagocytosis (n=28/45, 62%), central nervous system involvement (n=12/41, 29%). Five patients died; of 8 who reactivated, 4 underwent bone marrow transplantation. An associated/underlying disease was reported in 34/54 (62%): rheumatologic/autoimmune disorder, 22 (11 Juvenile Idiopathic Arthritis, 2 Kawasaki disease, Systemic lupus erythematosus, Cogan Syndrome, colitis ulcerosa; 6 undefined); lymphoproliferative disease, 5 (2 acute lymphoblastic leukemia, 2 non-Hodgkin and 1 Hodgkin lymphoma), infectious diseases, 6 (2 EBV, 1 CMV, 1 parechovirus, 1 osteomyelitis, 1 myocarditis) and 1 pigment deficiency disease. Functional tests were performed in 32/54 (60%), showing impaired degranulation in 42% (n=13/31) and defective perforin expression in 43% (n=16/37). The genetic study revealed 31 monoallelic variants in *PRF1* (n=10)*, UNC13D* (n=9), *STX11* (n=5), *STXBP2* (n=12), *LYST* (n=1) and *Rab27A* (n=1). Four variants were reported as polymorphism. Of the 25 remaining, 23 were missense (9 predicted as benign and 14 as probably damaging), 1 STOP and 1 frameshift both predicted as probably damaging. Two patients had mutations in 2 different genes.
Summary/Conclusions: 9% of patients reported to the Italian HLH Registry carries monoallelic variants in at least one FHL-related genes, including 37% being probably damaging. Altogether these patients are characterized by later onset, partial/milder disease, and partial functional defect. Thus, monoallelic mutation in one FHL-related gene defines a predisposing factor for HLH.

B. Rossi, Verona, [11]Department of Pediatric Haemato-Oncology, University of Catania, Catania, [12]Department of Haematology, Ca'Foncello Hospital, Treviso, Italy

Background: Erythrocytosis, (i.e. increased levels of hemoglobin /hematrocit (Hb/Htc) >95percentile for age and sex), is rarely found in pediatric or adolescent age. Presence of familial cases, presentation at birth or presence of known mutations, as well as exclusion of secondary causes identifies primary (PE) or congenital secondary forms (CE). However, many cases still lack evident etiological definition (Idiopatic E.). Moreover, natural course and treatment are still anecdotally reported.
Aims: Here we present our experience in a large and heterogeous series of children with absolute erythrocytosis. The aims is to identify a possible clinical and diagnostic approach to children with erythrocytosis
Methods: All children with E. who lacked evidence of reactive origin were consecutively referred to our laboratory for molecular evaluation. Molecular analysis of the main involved genes (VHL, HIF2A, EPOR, JAK2, PHD2) was performed by allele specific PCR, PCR on direct DNA sequencing. Erythopoietic Colony Essay (EEC) was performed on peripheral blood with and without cytokines. Clinical features and treatment choices were reported by referring clinicians (table 1).

Table 1.

Category	Families (n)	Children (adults) (n)	Gene Defects /transmission	EPO	Splenomegaly	Thrombosis	Vascular symptoms	Notes

Sporadic, classic PD		18M /3 F	NO			18.8/48.1	8 YES (headach e, abdominal pain, [illegible], & dizziness, pruritus) 13 NO	
PV		1F	JAK2V617F	Suppressed	Y	18.7/52	Y	ASA, phlebotomy

Results: Patients were group according to the definitons of absolute Eryhtrocytosis. A total of 44 pediatric cases were identified (less than 18 years old). There were 7 families, where 5 adults were also found polyglobulic. However, in only 4 families a defect was identified (2 VHL, and 2 Hb variants). One HIF positive case was found sporadic. Most Hb variants were not symptomatic, while all other familiar cases had splenomegaly and vascular symptoms.Among non familial, non genetic cases, 5 children were affected by Down Syndrome; 4 children had severe renal or cerebral disease. In one 4 year old girl, with a polymorphic VHL variant, who presented with arterial hypertension, a small size ganglioneuroma was found after a 5yrs follow-up. In 21 cases non causes could be identified. They were mostly male (n18); presented at adolescent age with advanced puberal status (n17); many were symptomatic (6). Only one 9 year old girl was diagnosed with Polycytemia vera (JAK2V617F positive). Treatment varied according to physician decisions and presence of vascular symptoms, 6 children received ASA and 11 were phlebotomysed. In two older patients severe vascular complications were observed (arterial thrombosis), even with Htc<45%.
Summary/Conclusions: This series shows the heterogeneity of Eryhtrocytosis as found in pediatrics. Extensive clinical and genetic analysis are required but still a large number of cases lack clear definitions. The usefulness of antiaggregation and phlebotomy is not proved.

Background: Neurological involvement is poorly described in autoimmune cytopenias (AIC), containing immune thrombocytopenia (ITP), autoimmune hemolytic anemia (AIHA) and Evans syndrome (ES). This association suggests an underlying primary immunodeficiency (PID).
Aims: To describe neurological involvement observed in autoimmune cytopenias, evolution under treatment and PID profiles in these patients.
Methods: OBS'CEREVANCE is a French nationwide prospective cohort including children with an AIC since 2004. Patients with a neurological involvement were analyzed excluding neurological symptoms related to a traumatism or isolated febrile seizures. Clinical, radiological and biological data were collected from primary centers. Centralized radiological review was performed. Genetic analyses were performed by Sanger gene sequencing or gene-panel based next generation sequencing.
Results: On October 2016, among the 1,167 patients of the cohort (371 AHAI, 615 ITP, 181 ES), a significant neurological involvement was observed in 8 patients from 7 centers. With a median (range) follow-up of 12 years (6-26.5), 7 children had ES (including autoimmune neutropenia in 5) and 1 child had isolated AIHA. Median age at initial cytopenia was 11.5 years (1.6-15.8). At the last follow-up point, AIC were in partial or complete remission for all patients. Neurological symptoms appeared with a mean delay of 6 years (2.5-18) after AIC onset. The symptomatology was: seizures (n=4), cranial nerve palsy (n=2), Brown-Sequard syndrome (n=2) and / or sensory neuronopathy (n=1). No infectious pathogens were identified. MRI showed multiple (n=6) or unique (n=2) inflammatory lesions with hyperintense T2 signal in all patients, gadolinium-enhancing lesions in 7 and perilesional edema in 5. Five patients had a total of 8 biopsies, which confirmed the inflammatory process with macrophagic (n=3) or lymphoplasmocytic (n=5) infiltrates. In 4 cases, a lymphocytic meningitis was associated. Non-neurological organ involvement was present in all patients, mainly pulmonary nodules (n=6) and lymphoproliferation (n=4). All patients had an abnormal immunophenotype, with T-cell (n=7) or B-cell (n=3) deficiency and hypogammaglobulinemia was present in 7 of the 8 cases. Patients have been given steroids (n=6), intravenous immunoglobulins (n=2) or immunosuppressive treatment (n=3, Ciclosporin, Mycophenolate Mofetil and Methotrexate), improving symptomatology and MRI for all. Five patients relapsed and 3 patients had an asymptomatic radiological progression. At the last follow up point, all patients had neurological sequels and 7 persisting radiological abnormalities. Four out of the 6 patients analyzed had a PID: 22q11.2 microdeletion (n=1), heterozygous *CTLA* mutation (n=2) or homozygous *LRBA* mutation (n=1).
Summary/Conclusions: Neurological involvement is a rare and severe late event in the course of childhood ES, or exceptionally AHAI, that may reveal various underlying PID. Complete imaging and pathology examination highlight a causative immune dysregulation and could guide specific therapeutic strategies.

P717

AUTOIMMUNE NEUTROPENIA OF CHILDHOOD SECONDARY TO OTHER AUTOIMMUNE DISORDERS: DATA FROM THE ITALIAN NEUTROPENIA REGISTRY

Background: The most frequent Autoimmune Neutropenia (AIN) in childhood is the primary type (p-AIN), whereas in adults AIN is mostly represented by secondary neutropenias, which can be associated to infection, drug administration, immunodeficiency, neoplasms, bone marrow transplantation or other autoimmune disorders.
Aims: To describe clinic and laboratory findings in children affected by AIN secondary to other autoimmune diseases (s-AIN).
Methods: This registry study analyzes 26 patients affected by s-AIN enrolled in the Italian neutropenia registry of A.I.E.O.P. (Associazione Italiana di Onco-Ematologia Pediatrica) over a 15-year time-span: this cohort, the largest ever described, was compared to 263 patients affected by p-AIN enrolled in the Registry in the same period.

Table 1.

Sex	Age at onset (y)	Recovery from AIN	Age at recovery (y)	Associated autoimmunity
M	15,12	yes	15,89	ES (AIN+thrombocytopenia); DAT pos)
F	13,88	yes	14,12	Celiac disease; Autoimmune thyroiditis (anti-TPO pos)
I	2	no		Autoimmune hepatitis; ES (AIN+ thrombocytopenia); DAT pos
F	7,87	no		IDDM; ANA 1:320
M	5,6	no		Celiac disease; ES (AIN+ thrombocytopenia); DAT pos
M	10,82	no		ES (tri-lineage); ANA 1:160; GH deficiency
F	2,76	no		ES (tri-lineage); autoimmune encephalitis
M	13,43	no		ES (AIN+ thrombocytopenia); DAT pos
M	4,02	no		ES (AIN+ thrombocytopenia); ANA 1:320; arthritis
M	0,5	no		ES (AIN + AIHA)
M	17,17	no		ES (tri-lineage); ANA 1:160
I	17,49	no		ES (tri-lineage); ANA 1:640; SLE
F	12,33	no		ES (tri-lineage); ANA 1:160;
F	15,55	no		Autoimmune thyroiditis (anti-TPO pos; anti-TG pos)
F	13,45	no		Autoimmune thyroiditis (anti-TPO pos; anti-TG pos)
I	7,45	no		Autoimmune thyroiditis (anti-TG pos)
M	7,46	no		Autoimmune thyroiditis (anti-TPO pos)
I	16,47	no		Autoimmune thyroiditis (anti-TPO pos; anti-TG pos); ANA 1:1280
M	9,54	no		Autoimmune thyroiditis (anti-TG pos); ANA 1:320
F	11,98	no		GH deficiency; ANA 1:320
I	7,4	no		GH deficiency; ANA 1:320
M	12,49	no		IDDM
F	0,61	no		ANA 1:160; arthralgia; ASMA pos; anti-GAD pos
I	4,2	no		ANA 1:1280; arthralgia
I	2,65	no		ANA 1:320; arthralgia; anti-DNA pos
I	4,1	no		ANA 1:320; arthralgia

ES: ES syndrome; pos: positivity; AIN: autoimmune neutropenia; DAT: direct antiglobulin test; anti-TPO: *anti-thyroid* peroxidase antibodies; IDDM: insulin dependent diabetes mellitus; ANA: *antinuclear antibodies*; *GH*: growth hormone; anti TG: AIHA: autoimmune hemolytic anemia; anti TG: *anti thyroglobulin* antibodies; ASMA: anti smooth muscle antibodies; anti GAD: anti glutamic acid decarboxylase antibodies; anti-DNA: *anti*-double stranded DNA antibodies; SLE: *Systemic lupus* erythematosus.

Results: Specific characteristics of s-AIN patients are presented in Figure 1. The prevalence of former preterm babies among p-AIN (and not s-AIN) patients was significantly higher than in a cohort of 487 consecutively hospitalized children (p=0.008362). The median age of onset of AIN was 0.77 year and 10.07 year in p-AIN and s-AIN respectively (p=1.105e-12). The prevalence of selected IgA deficiency was 3% in p-AIN and 13.6% in s-AIN children: both prevalences were significantly higher than that (0.21%) of a group of 470 controls (p=0.0009 in p-AIN and p=7.239e-12 in s-AIN). Median value of neutrophils was lower in p-AIN (0.45 x 10^9/L) than in s-AIN 0.63 x 10^9/L (p =0.03); median value of lymphocytes was significantly reduced (p=6.29e-11) in s-AIN (1.58 x 10^9/L) *vs* p-AIN (4.36 x 10^9/L) group. Leucopenia (p=1.80e-07) and severe infections (p=0.0001) occurred more frequently in s-AIN; monocytosis (p=0.039) and spontaneous remission (p=3.21e-11) in p-AIN. GCSF was used in 6.9% of the p-AIN and 23.1% of the s-AIN patients (p=0.0045). Neutropenia appeared contemporarily to other autoimmune manifestations in 11/26 s-AIN patients (42.3%), appeared firstly in 8/26 patients (30.7%) (median and mean time of appearance of other autoimmune signs: 440 and 987 days respectively) and later in 7/26 patients (26.9%) (median and mean time of appearance of s-AIN: 558.5 and 865.3 days respectively). Evans Syndrome (ES) and autoimmune thyroiditis (AT) were the most common secondary autoimmune diseases (11 and 7 patients, respectively), whereas 7 s-AIN patients presented not previously reported associations: 3 with GH deficiency, 2 with coeliac disease (CD), 1 with autoimmune hepatitis (AH) and 1 with autoimmune encephalitis. In 6 children s-AIN was associated with more than one defined autoimmune disease and in 4 children with *undefined* autoimmune signs characterized by arthralgia and ANA positivity. Finally, only 2/26 patients presented spontaneous remission: a boy who recovered from ES and one patient, affected by both AT and CD who, after starting gluten-free diet, recovered from s-AIN (and not from AT). A third girl suffering from both AH and bi-lineage ES (thrombocytopenia + AIN) has been maintained, 30 months after the stop therapy, a stable remission from AH and thrombocytopenia (but not from s-AIN).

Summary/Conclusions: p-AIN is in the vast majority of cases a benign and self-limiting disorder typically occurring under 2-3 years old whereas s-AIN is a more severe disease, usually appearing after the first 5 years of life, usually associated to lymphocytopenia and with a highly frequent tendency to become chronic.

P718

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA TREATMENT DURING PREGNANCY

M. Vinogradova[1,*], A. Kulagin[2], T. Kirsanova[1], N. Klimenchenko[3], R. Shmakov[3]
[1]hematology, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, [2]hematology, 1st Saint Petersburg State Medical University, Saint Petersburg, [3]obstetrics, Federal Scientific Center for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a life-threatening disorder with a high risk of thrombosis. Targeted therapy radically changed the prognosis in PNH. Therefore issues of reproductive health in PNH patients are becoming very important. Recently the management of PNH during pregnancy has been challenging because of the high risk of maternal morbidity and frequent pregnancy loss. The combination of targeted therapy with eculizumab and anticoagulants made it possible not only to increase the survival rate, but also to improve the quality of life
Aims: We compared the pregnancy outcomes in PNH patients on eculizumab treatment and retrospective data of pregnancies on symptomatic therapy only.
Methods: Since 1999 we have analyzed 32 pregnancies in PNH patients. 17 patients (group 1) from 2013 exposed to eculizumab during pregnancy with anticoagulants. Other 15 women (group 2) received only symptomatic therapy. The median of PNH granulocyte clone at that time was 74,7% (23-99). PNH diagnosed before the pregnancy in all cases. 64,3% of them had previously received immunosuppressive treatment of aplastic anemia. 18,7% patients registered venous thromboses before conception. 92,9% of patients had been using eculizumab prior to becoming pregnant, mean duration of therapy was 21 months (4-44). Anticoagulation with low molecular weight heparin was used in 85,7% pregnancies.
Results: Clinical manifestations of hemolysis significantly regressed during eculizumab treatment: normalization of LDH was registered in 76,5% patients. Without eculizumab LDH level increased in all pregnant patients. No maternal death and thrombotic events have been observed. 42,9% of patients required a dose adjustment due to breakthrough hemolysis (a dose increase and/or more frequent use of eculizumab). Pregnancy complications were less frequent with eculizumab: abortion threat 35,3% *vs* 85,7%, fetal growth retardation syndrome 7,1% *vs* 21,4%, preeclampsia 5,9% *vs* 14,3%. Transfusion rate was higher without eculizumab (86,7% *vs* 41,2%). Pregnancies resulted in the birth in 100% patients exposed eculizumab and 42,9% on supportive treatment. Mean birth weight 2560 g (450-3550). Most of newborns (87,5%) are healthy, 83,3% of them received breastfeeding without complications both on eculizumab and without it.
Summary/Conclusions: We can conclude that pregnancy outcomes in PNH patients with eculizumab are much better than with symptomatic therapy only. Our data demonstrate the possibility of safe therapy with eculizumab in pregnant women. Pregnancy does not worsen the prognosis of PNH in the case of targeted and adequate supportive therapy. There is no difference in health between infants born by mothers with PNH and the newborns from general population.

Platelet disorders: Clinical

P719

LONG-TERM RESPONSE TO ORAL ELIGLUSTAT IN TREATMENT-NAÏVE ADULTS WITH GAUCHER DISEASE TYPE 1: FINAL EFFICACY AND SAFETY RESULTS FROM A PHASE 2 CLINICAL TRIAL AFTER 8 YEARS OF TREATMENT

E. Lukina[1,*], N. Watman[2], M. Dragosky[3], H. Lau[4], E. Avila Arreguin[5], H. Rosenbaum[6], Y. Wu[7], S. Gaemers[7], M.J. Peterschmitt[7]
[1]National Research Center for Hematology, Moscow, Russian Federation, [2]Hospital Ramos Mejia, [3]IMAI-Research, Buenos Aires, Argentina, [4]New York University School of Medicine, New York, United States, [5]Instituto Mexicano del Seguro Social Hospital de Especialidades, Col. La Raza, Mexico, [6]Rambam Medical Center, Haifa, Israel, [7]Sanofi Genzyme, Cambridge, United States

Background: In Gaucher disease type 1 (GD1), deficient lysosomal acid β-glucosidase activity leads to accumulation of glucosylceramide, primarily in macrophages (Gaucher cells), which deposit in the spleen, liver, and bone marrow, leading to thrombocytopenia, anemia, hepatosplenomegaly, and skeletal disease. Hematologists often identify and manage the disease. Intravenous enzyme replacement therapy (ERT) with recombinant acid β-glucosidase has been the mainstay of therapy for GD1. Eliglustat is an oral substrate reduction therapy approved as first-line treatment for adults with GD1 with poor, intermediate, or extensive CYP2D6-metabolizer phenotypes (>90% of patients). Phase 3 trials demonstrated safety and efficacy of eliglustat in naïve patients (Mistry *et al. JAMA*. 2015) and safety and stability in patients switching from long-term ERT (Cox *et al. Blood.* 2017). We report the final 8-year results of an open-label Phase 2 trial (NCT00358150, Sanofi Genzyme) in previously untreated adults with GD1. These data build on 1-, 2-, and 4-year data showing sustained improvements in hematologic parameters, organ volumes, disease-related biomarkers, and measures of bone health (Lukina *et al. Blood Cells Mol Dis*. 2014).
Aims: Report long-term efficacy and safety after long-term eliglustat treatment.
Methods: Adult GD1 patients who had splenomegaly with thrombocytopenia and/or anemia received 50 or 100mg eliglustat tartrate (equivalent to 42 or 84mg eliglustat) twice daily, dosed by plasma trough levels. Efficacy outcomes included changes in hemoglobin, platelets, spleen and liver volumes, disease-related biomarker levels, skeletal manifestations, and achievement of therapeutic goals for anemia, thrombocytopenia, splenomegaly, and hepatomegaly (Pastores *et al. Semin Hematol.* 2004; Lukina *et al. Blood.* 2010).
Results: Of 26 enrolled patients, 19 completed the trial and 7 withdrew: 2 on the first day of treatment due to asymptomatic nonsustained ventricular tachycardia detected during routine monitoring (plasma levels of eliglustat were undetectable); 1 after 1 year due to progression of a bone lesion (retrospectively identified at baseline); 1 chose to withdraw after 2 years; and 3 due to pregnancy. After 8 years of eliglustat, mean (±SD) hemoglobin level and platelet count increased by 2.1±1.7 g/dL (from 11.3±1.6 to 13.4±1.3 g/dL) and 110% (from 67.5±21.1 to 130.7±59.8 x10^9/L), respectively. Mean spleen and liver volumes (multiples of normal, MN) decreased by 68% (from 17.3±10.4 to 5.1±3.5 MN) and 31% (from 1.6±0.5 to 1.1±0.3 MN), respectively. All patients met ≥3 of 4 long-term therapeutic goals (spleen, 100% of patients; liver, 100%; hemoglobin, 93%; platelets, 53%) by 7-8 years. Median chitotriosidase levels decreased by 84%, CCL-18 by 82%, and glucosylsphingosine (Lyso GL-1) by 88%; plasma GL-1 normalized. Total mean lumbar spine bone mineral density increased by 0.12 g/cm^2; mean Z-score increased by 0.88 (from -1.27±1.02 to -0.39±1.13) and mean T-score by 0.95 (from -1.64±1.07 to -0.69±1.31). Eliglustat was well-tolerated. All quality of life measures (SF-36, fatigue severity score, Gaucher disease severity score) showed improvement over time. Most adverse events in this long-term trial were mild or moderate in severity (98%, 342/348) and considered unrelated (94%, 328/348) to treatment.
Summary/Conclusions: After 8 years of treatment with eliglustat, clinically meaningful improvements in hematologic, visceral, biomarker, and bone parameters continued or were maintained among patients in this Phase 2 trial. No new safety concerns emerged.

P720

REAL WORLD EVIDENCE ON DRUG UTILIZATION PATTERNS OF ELTROMBOPAG IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA: REVIEU (REVOLADE™ [ELTROMBOPAG] IN SELECTED COUNTRIES IN THE EUROPEAN UNION) STUDY

E.O. Gutiérrez[1,*], A. Salama[2], J.-F. Viallard[3], R.G. Delgado[4], M.E. Mingot-Castellano[5], E. Quebe-Fehling[6], O.A. Ozlem[6], A. Allepuz[6], T.J. González-López[7]
[1]Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain, [2]Charite Universitätsmedizin Berlin, Berlin, Germany, [3]Hôpital Haut Lévêque Centre F.Magendie Avenue de Magellan, Bordeaux, France, [4]Hospital Clínico Universitario Virgen de la Victoria Campus Universitario de Teatinos s/n, [5]Hospital Regional Universitario de Málaga Avenida Carlos Haya s/n, Malaga, Spain, [6]Novartis Pharma AG, Basel, Switzerland, [7]Hospital Universitario de Burgos Avda. Islas Baleares s/n, Burgos, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by isolated thrombocytopenia, with platelet counts <100x10^9/L. Eltrombopag is an oral small-molecule nonpeptide thrombopoietin-receptor agonist that has shown to increase platelet production. It is approved for the management of patients with chronic ITP (aged ≥1 year) who are refractory to other treatments (eg, corticosteroids, immunoglobulins). The recommended eltrombopag dose in patients with chronic ITP is 25mg once daily, OD (East Asians, 12.5mg OD or 25mg every other day) in pediatrics aged 1-5 years, and 50mg OD (East Asians, 25mg OD) in adults and pediatrics aged 6-17 years at initiation, followed by dose adjustment to a maximum of 75mg OD based on platelet counts. REVIEU study was conducted in accordance with risk management plan in five European Union (EU) countries to document eltrombopag utilization patterns in real-world practice. Here, we report the eltrombopag data on the subset of adult patients (aged ≥18 years) with ITP as primary diagnosis.
Aims: To evaluate the real-world data to determine drug utilization patterns among adult patients with ITP receiving eltrombopag within five EU countries.
Methods: REVIEU study was a multinational, multicenter, retrospective, medical chart review in patients with a documented past treatment with eltrombopag between the period immediately after first approval/launch in May 2010 and September 2014 (ie, dispensed at least once by the pharmacy and patient received at least one dose) for whatever reason. Patients who participated or were participating in a randomized eltrombopag clinical trial were excluded.

Table 1.

Table 1. Proportion of patients with platelet counts by ITP disease phase, and by eltrombopag dose

Platelet count and eltrombopag dose, n (%)	Acute ITP (n=39)		Persistent ITP (n=31)		Chronic ITP (n=216)		Total (N=287)	
	At initiation (n=36)	At dose change (n=25)	At initiation (n=30)	At dose change (n=29)	At initiation (n=211)	At dose change (n=164)	At initiation (n=277)	At dose change (n=218)

100 - <250 x 10^9/L	0 (0)	1 (4)	0 (0)	0 (0)	1 (0.5)	0 (0)	1 (0.4)	1 (0.5)
≥250 x 10^9/L	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)

Results: Overall, 287 adult patients with ITP (chronic [>12 months], 75.3%; persistent [3-12 months], 10.8%; acute [<3 months], 13.6%; unknown [n=1]) were included, majority in Spain (n=128) followed by Italy (n=67), Greece (n=36), France (n=29), and Germany (n=27). Eltrombopag was the first treatment with no prior ITP therapies in 12 (4.2%) [acute, 10.3%; persistent, 6.5%; chronic, 2.8%] patients. A total of 99 (34.6%) patients received one prior therapy (corticosteroids, 79 [27.6%]), 128 (44.8%) patients received two prior therapies (corticosteroids+immunoglobulin, 114 [39.9%]), and 47 (16.4%) patients received three prior therapies (corticosteroids, immunoglobulins, and splenectomy). In total, the majority of patients received at least one prescription of corticosteroids (252, 88.1%) followed by immunoglobulins (180, 62.9%), and splenectomy (64, 22.4%) prior to eltrombopag initiation. Patients received an average daily dose of eltrombopag 45.6mg (chronic ITP, 44.6mg; persistent ITP, 43.1mg; acute ITP, 53.0mg) during the study. Overall, dose changes were reported in 749 adult ITP prescriptions (down-titration, 53.7%; up-titration, 43.7%; no change in dose, 2.7%). 49.1% of dose changes were reported during the first 6 months of treatment (35% in first 3 months). The main reasons for dose change included: disease improvement (30.4%), no treatment response (26.8%) and others (27.1%). Disease improvement accounted for down-titration in 51.2% (206/402) and up-titration in 4.6% (15/327), and no treatment response for up-titration in 54.4% (178/327) and down-titration in 5.0% (20/402) of adult patients with ITP. Proportion of patients with platelet counts by ITP disease phase, and by eltrombopag dose are reported in **Table 1**.
Summary/Conclusions: The majority of adult patients with ITP (75.3%) were diagnosed with chronic ITP, and were treated with eltrombopag as second-line or greater therapy after corticosteroids and immunoglobulins, in line with the approved indication. Eltrombopag was also prescribed in 24.4% of adult patients with acute and persistent ITP. The starting dose followed the summary of product characteristics (SmPC) recommendations in the majority of cases and dose modifications were generally according to platelet counts. Data from REVIEU study have shown that eltrombopag use in the real world setting is largely consistent with the EU label and is considered part of ITP medical therapies.

P721

BIOLOGICAL CHARACTERIZATION OF ITP PATIENTS THAT ARE NON-RESPONDERS TO TRADITIONAL THERAPIES

Grupo de investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance in immune thrombocytopenia (ITP) (1). Antibody-mediated platelet desialylation may lead to platelet clearance in the liver via hepatic Ashwell–Morell receptors, providing a potential explanation for refractoriness to classical therapies (steroid, IVIG and splenectomy).
Aims: The aim of this study was to analyze the biological features of ITP patients refractory to conventional therapies.
Methods: We performed a prospective study in 8 patients with primary ITP not responding to standard therapies (coticosteroids, IVIG and/or splenectomy) as well as in 8 patients with non-refractory ITP (control group). Mean platelet size, surface expression of platelet glycoprotein (GP) IIb,and the activation marker CD62 were examined by flow cytometry (FC) analysis, as well as desialylation of platelet membrane GPs using fluorescein-conjugated *Ricinus Communis* Agglutinin I (RCA-1), a lectin that binds to galactose residues underlying sialic acids. Patients' sera was also incubated with normal human platelets to analyze their ability to induce desialylation in normal platelets. Analysis of desialylation of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (transferrin). The specificity of platelet autoantibodies was assessed by a solid-phase modified antigen capture ELISA test (MACE). FC results are expressed as ratio of mean fluorescence intensity (MFI) compared to that of a control.
Results: The characteristics of the patients according to the response to conventional treatments (A, no responsers; B, responders) are summarized in Table 1. Non responders exhibited lower platelet counts (p=0.006), higher expression of GPIIb (p=0.049) and loss of platelet sialic acids (p=0.005). Additionally, those who did not respond not only to traditional therapies (corticosteroids, IVIG and splenectomy) but also to thrombopoietin receptor agonists (TPO-RA) (n=5) displayed higher platelet size and alpha-granule secretion. Furthermore, TPO-RA refractory patients' sera desilylated normal platelets, but not plasma proteins. MACE assay revealed that unique positivity for anti-GPIbα antibodies was only detected in those patients classified as non-responders to conventional ITP therapies, including TPO-RA.

Table 1. Patients' characteristics

	Group A: Refractory ITP to conventional treatment (n=8)	Group B: ITP with response to conventional treatment (n=8)	
Age(y) Median (range)	55 (22-79)	30 (20-63)	
Sex (male/female)	4/4	3/5	
Splenectomized	50%	75%	
Platelet count ($x10^9$/L) Mean ± standard error	40 +/- 54 Refractory to TPO-RA(n=5): 4 +/- 6 Response to TPO-RA(n=3): 97 +/- 49	260 +/- 172	*p=0.006
FSC (ratio)	1.81 +/- 1.54 Refractory to TPO-RA(n=5): 1.96 +/- 1.85 Response to TPO-RA(n=3): 0.90 +/- 0.30	1.21 +/- 0.38	p=0.430
GPIIb (ratio)	1.93 +/- 1.02 Refractory to TPO-RA(n=5): 1.91 +/- 1.42 Response to TPO-RA(n=3): 1.33 +/- 0.65	1.06 +/- 0.14	*p=0.049
CD62-P expression in patient platelets (ratio)	4.40 +/- 3.38 Refractory to TPO-RA(n=5): 4.87 +/- 4.16 Response to TPO-RA(n=3): 2.14 +/- 1.06	2.49 +/- 2.78	p=0.064
RCA-1 expression in patient platelets (ratio)	3.01 +/- 2.45 Refractory to TPO-RA(n=5): 3.35 +/- 3.04 Response to TPO-RA(n=3): 1.46 +/- 0.34	1.10 +/- 0.29	*p=0.005
RCA-1 expression in control platelets, patient sera (ratio)	1.57 +/- 0.86 Refractory to TPO-RA(n=5): 1.72 +/- 0.99 Response to TPO-RA(n=3): 1.19 +/- 0.33	1.29 +/- 0.78	p=0.247
Platelet autoantibody specificity	Refractory to TPO-RA(n=5): -GPIbα: 2/5 -GPIIb/IIIa: 2/5 -Both: 1/5 -Negative: 0 Response to TPO-RA(n=3): -GPIbα: 0 -GPIIb/IIIa: 1/3 -Both: 0 -Negative: 2/3	-GPIbα: 0 -GPIIb/IIIa: 1/8 -Both: 1/8 -Negative: 6/8	

Patients who did not achieve complete platelet responses to splenectomy, corticosteroids and / or immunoglobulins were considered refractory (group A). Group A has been subdivided as refractory or not to TPO-RA. Flow cytometry results are expressed as mean fluorescence intensity ratio compared to a parallel healthy control. Abbreviations: TPO-RA, thrombopoietin receptor agonist.

Summary/Conclusions: This study shows a significant higher platelet desialylation in ITP patients who are non-responders to conventional therapies, particularly if they are also refractory to TPO-RA. According to a previous study (1), these results seem to be associated to platelet activation mediated by antiplatelet specific antibodies.

Background: ITP is a disorder characterized by thrombocytopenia resulting from both increased immune-mediated platelet clearance and inappropriate thrombocytopoieis. TPO-RAs–romiplostim (R) and eltrombopag (E) - offer a new opportunity of treatment with high response rates. However, a small fraction of pts does not respond or loses response - *i.e.* desired platelet (plt) count achieved but not sustained over time - during long-term follow-up, which can not be resumed even if dosage is increased over time, or experience wide fluctuations in plt counts with either agent. Moreover, adverse events (AE) may necessitate treatment discontinuation. Finally, patient's preference may be an important issue considering the different route and timing of administration of the two agents and the alimentary restrictions needed for proper E absorption. Availability of two TPO-RAs for clinical use, with different molecular structure and site of binding within the TPO receptor, has prompted trials of TPO-RA switching with the aim of overcoming treatment limitations of either agent resulting in reported overall response rates of approximately 80% in poor responders to 1st TPO-RA.
Aims: To present the results of a multicenter survey on TPO-RA switch policies and outcome.
Methods: Charts of ITP pts receiving TPO-RAs at 17 collaborating Haematology Centers were reviewed; demographic and clinical data were collected in a dedicated case report form. Pts were grouped and analyzed based on the clinical setting prompting the switch (Table 1). The study was approved by the Hospital Review Board of each participating Center.

Table 1.

Table 1		Reason for switching				
	Patients	1st TPO-RA failure	Loss of response	Fluctuation	Patients' preference	Adverse events
Number	106	51 (48.1%)	20 (18.9%)	11 (10.4%)	8 (7.6%)	16 (15.0%)
eltr-> rom	47 (44.3%)	27 (52.9%)	5 (25%)	2 (18.2%)	0 (0%)	13 (81.3%)
rom -> eltr	59 (55.7%)	24 (47.1%)	15 (75%)	9 (81.8%)	8 (100%)	3 (18.7%)
Max dose used	72 (67.9%)	41 (80.4%)	15 (75%)	5 (45.5%)	5 (62.5%)	6 (37.5%)
No response	37 (34.9%)	26 (51%)	4 (20%)	2 (18.2%)	3 (37.5%)	2 (12.4%)
Response	39 (36.8%)	17 (33.3%)	4 (20%)	4 (36.4%)	3 (37.5%)	11 (68.8%)
Complete Response	30 (28.3%)	8 (15.7%)	12 (60%)	5 (45.4%)	2 (25%)	3 (18.8%)

Results: A total of 546 pts received either R or E between Dec 2009 and Dec 2015. Of these, 106 (19.4%) underwent TPO-RA switch. Table 1 summarizes outcome after switch. Overall 69/106 (65%) of pts achieved, regained or maintained response upon switching. Either one TPO-RA switch sequence was equally effective (p=0.682). Outcome was not associated with gender, age at 1st TPO-RA treatment, splenectomy status. However, number of lines of previous therapies was associated with lower response rates (p=0.020): each additional line of therapy yielded a 30% increase in the odds of being a non responder; a trend toward lower probability of response was observed in pts with longer lasting disease before 1st TPO-RA administration (p=0.066). Adverse events (AE; 16/106 pts) were generally mild and reversible upon discontinuation of either one TPO-RA; 1 arterial (managed with thromboendarterectomy) and 1 venous (standard anticoagulation) thrombotic events were observed which did not recur after switching. AE were characteristic of older pts: each additional year increase in pts age determined a 5% increase in the odds of developing AE.
Summary/Conclusions: Approximately 20% of TPO-RA treated pts were felt by their attending physicians to potentially benefit from a switching policy. Exposure to the 2nd TPO-RA was more effective in pts who had lost response to 1st TPO-RA (80% responders) compared to those who were non responders to 1st TPO-RA (49% responders, p=0.001). It could be speculated that lack of response to either one of the two available TPO-RA identifies a subgroup of pts least likely to respond when switched to the second available TPO-RA. Pts switched for non-efficacy reasons are more likely to maintain a response upon switch (p=0.030). The so far unexplained and unprecedented phenomenon of wide plt fluctuation appears to be linked to the removal of the spleen, the physiological plt reservoir organ

P723

THROMBOEMBOLIC EVENT MANAGEMENT AND OUTCOMES IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP) DURING TREATMENT WITH ELTROMBOPAG (EPAG): RESULTS FROM THE EXTEND STUDY

M.N. Saleh[1,*], J.B. Bussel[2], R.S. Wong[3], B. Meddeb[4], A. Salama[5], O. Ocak[6], S. Atkinson[6], E. Quebe-Fehling[6], A. Khelif[7]
[1]Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, [2]Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, United States, [3]Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, Chinese University of Hong Kong, Shatin, Hong Kong, [4]Hôpital Aziza Othmana, Tunis, Tunisia, [5]Charite-Universitätsmedizin, Berlin, Germany, [6]Novartis Pharma AG, Basel, Switzerland, [7]Hôpital Farhat Hached, Sousse, Tunisia

Background: EPAG is an oral thrombopoietin receptor agonist approved for treatment of previously treated patients (pts; eg corticosteroids, immunoglobulins) with cITP aged ≥1 yr. The EXTEND study, a global, open-label, extension study of pts with cITP who received EPAG or placebo in prior EPAG studies, evaluated long-term safety and tolerability of EPAG. In EXTEND, 19 (6.3%) pts receiving EPAG experienced a total of 24 thromboembolic events (TEEs; Saleh *et al. Blood* 2016;128:1368), which is similar to TEE incidence in cITP pts receiving romiplostim (Kuter *et al. Br J Haematol* 2013;161:411–23) and to one estimate in the general cITP population (Sarpatwari *et al. Haematologica* 2010;95:1167-75).
Aims: To describe management and outcomes of TEEs occurring during EPAG treatment in the EXTEND study.
Methods: Adult pts with cITP received EPAG starting at 50mg/day, with titration to 25–75mg per day or less as required, based on individual platelet count responses (target range ≥50–200x10^9/L). Maintenance dosing continued after minimization of concomitant ITP medication and optimization of EPAG dosing. Pts could remain on EPAG either for 2 yrs in countries where EPAG was commercially available, or for >2 yrs until EPAG became commercially available. The EXTEND primary objective included detection and documentation of AEs, including investigator-reported TEEs.
Results: 302 pts were enrolled and received ≥1 EPAG dose: 67% female; 38% splenectomized; 49% aged 18-49 yrs. Median exposure duration was 2.4 yrs (range, 2 days to 8.8 yrs) and mean daily dose was 50.2 (range, 1-75)mg/day. Overall, 259/302 (86%) pts achieved platelet counts of ≥50×10^9/L at least once and 126/248 (51%) pts maintained continuous platelet counts ≥50×10^9/L for ≥31 weeks. TEEs during EPAG treatment (n=24 events) included deep vein thrombosis (DVT; n=8), myocardial infarction (MI; n=5), cerebral infarction (CI; n=4), transient ischemic attack (TIA; n=3), others (n=4) [Table]. Where available, platelet counts prior to TEE were <150×10^9/L in eight pts and ≥150×10^9/L in nine; 6 pts experienced the TEE at or shortly after achieving their maximum platelet count. Most TEEs resolved with intervention; 15 pts received anticoagulant therapy for 16 TEEs (treatment not recorded, n=3; no anticoagulation, n=5). EPAG was discontinued after a TEE (DVT, n=4; CI, n=3; MI, n=1; other, n=2) in 10 pts (n=9/10 TEE resolved). Seven pts continued to receive EPAG after a TEE (MI, n=3; TIA, n=3; CI, n=1; DVT, n=1; other, n=2; TEE resolved, n=8/10); in two cases, EPAG was continued with no anticoagulant therapy (TIA; both resolved), and in four, anticoagulants were given concomitantly with EPAG (TEE resolved, n=2/4); one of these also underwent percutaneous transluminal coronary angioplasty (MI, resolved). EPAG was interrupted during treatment for TEEs in two pts, one pt had two DVTs and acute MI (n=3/3 TEEs resolved), the other had a DVT (not resolved). TEE risk factors were not recorded for all pts; risk factor effect on the treating physician's management could not be analyzed.

Table 1.

Table. Occurrence of TEEs during eltrombopag treatment, eltrombopag treatment decision and number of resolved events by TEE

		Eltrombopag treatment decision*		
TEE	Total events	Discontinued	Continued	Interrupted
DVT, n (resolved, n)	8 (6)	4 (4)	1 (0)	3 (2)
MI, n (resolved, n)	5 (5)	1 (1)	3 (3)	1 (1)
CI, n (resolved, n)	4 (3)	3 (2)	1 (1)	0
TIA, n (resolved, n)	3 (3)	0	3 (3)	0
Other,† n (resolved, n)	4 (3)	2 (2)	2 (1)	0
Total, n (resolved, n)	24 (20)	10 (9)	10 (8)	4 (3)

*Three patients experienced more than one TEE during eltrombopag treatment
†Cerebral ischemia, pulmonary embolism, pulmonary infarction, thrombophlebitis (n=1 occurrence each)

Summary/Conclusions: This analysis shows that most pts who experienced a TEE had resolution of the event after medical/surgical treatment, most commonly anticoagulant therapy, regardless of whether EPAG was discontinued, interrupted or continued. The decision to restart EPAG following a TEE should be made on a case-by-case basis, with caution (including frequent platelet count monitoring) and only if the benefit is expected to outweigh any risk. If anticoagulation therapy is instituted (as in most cases), it is possible the bleeding risk may shift the risk-benefit to maintenance of EPAG treatment.

P724

SEVERE BLEEDING IN THE ELDERLY WITH PRIMARY IMMUNE THROMBOCYTOPENIA: CHARACTERISTICS, RESPONSE TO THERAPY AND LONG-TERM OUTCOME

M. Lyu[12,*], Y. Li[1], R. Fu[1], H. Li[1], F. Xue[1], X. Liu[1], L. Zhang[1], R. Yang[1]
[1]State Key Laboratory of Experimental Hematology, Institute Of Hematology And Blood Diseases Hospital, Chinese Academy Of Medical Sciences And Peking Union Medical College, Tianjin, [2]Department of Hematology, Affiliated Suzhou Hospital of Nanjing Medical University (Suzhou Municipal Hospital), Suzhou, China

Background: Primary immune thrombocytopenia (ITP) is often diagnosed in the elderly. The elderly patients have been reported to have a higher incidence of severe bleeding manifestations and a higher ITP-related mortality. Nonetheless, few data exist on the characteristics and long-term prognosis of elderly patients with severe bleeding.
Aims: We retrospectively evaluated elderly patients with ITP who had severe bleeding to determine characteristics, response to therapy and long-term outcome.
Methods: We reviewed the medical records of 517 ITP patients over 60 years of age diagnosed at our center (192 men and 325 women) between 1991 and 2012. Therapy was started at diagnosis or during follow up. Bleeding severity was assessed by the Mazzucconi's bleeding assessment. Logistic regression analysis was used to determine which presenting features were associated with the risk of severe bleeding. Cox regression analysis was used to estimate rate ratios(RR) for no remission and mortality.
Results: Among 517 patients with ITP, 10 (1.9%) presented intracerebral hemorrhage(ICH) and 74 (14.3%) presented severe (non-ICH) bleeding during ITP. According to multivariate analysis, risk of severe bleeding in patients was increased with platelet count <10×10^9/L (*P*=0.001, OR=1.682, 95% CI 1.271-2.234), female patients (*P*=0.010, OR=2.148, 95% CI 1.200-3.844), complication of pulmonary disease (*P*=0.001, OR=4.724, 95% CI 1.845-12.092), gum or oral mucosal bleeding (*P*<0.001, OR=2.941, 95% CI 1.658-5.216) and epistaxis (*P*=0.027, OR=1.865, 95% CI 1.074-3.238). Compared to severe (non-ICH) bleeding, ICH was more likely incurred in severe bleeding patients with hypertension (*P*=0.031, OR=2.750, 95% CI 1.266-5.974). Of 103 patients simply observed after diagnosis, 7(6.7%) patients presented severe (non-ICH) bleeding and 3(2.9%) patients presented ICH during ITP. Of 222 patients who had bleeding after treatment, 31 patients (13.9%) presented severe (non-ICH) bleeding and 4(1.8%) patients presented ICH. Compared to observation, treatment did not significantly reduce the risk of severe bleeding (χ^2=1.889, *P*=0.169). The total response rate (CR+R) to initial treatment in patients who presented severe bleeding was 58.1% (43/74), which was lower than that in patients without severe bleeding (70.2%, 238/340, χ^2=4.014, *P*=0.045). The response to steroids, IVIG or combination had no significant difference among

patients with severe bleeding. At the end of follow-up, the estimated 10-year cumulative rate of no remission among patients with severe bleeding was higher than that among patients without severe bleeding (*P*=0.017, RR=1.608, 95%CI, 1.052-2.456). The estimated 10-year cause-specific mortality related to fetal bleeding in patients with severe bleeding was higher than that in patients without severe bleeding (*P*<0.001, RR=9.886, 95% CI, 1.806-54.098). The estimated 10-year mortality among ICH patients was higher than that among severe (non-ICH) patients (*P*<0.009, RR= 4.543, 95% CI, 1.317-15.668).
Summary/Conclusions: Platelet count <10×10^9/L, female patients, complication of pulmonary disease, gum or oral mucosal bleeding and epistaxis are significant predictive factors for severe bleeding in the elderly. Severe bleeding in elderly ITP was associated with more failure of response to treatment, increased long-term risk of no remission and mortality related to fetal bleeding.

P725

ATORVASTATIN IMPROVE THE PROGNOSIS OF ADULT PATIENTS WITH CORTICOSTEROID-RESISTANT IMMUNE THROMBOCYTOPENIA VIA ENHANCING BONE MARROW ENDOTHELIAL CELL FUNCTION

Y. Kong[1], X.-N. Cao[1,*], X.-H. Zhang[1], M.-M. Shi[12], Y.-Y. Lai[1], Y.-Q. Sun[1], Y. Wang[1], L.-P. Xu[1], Y.-J. Chang[1], X.-J. Huang[12]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Immune thrombocytopenia (ITP) is generally considered to be an autoimmune disorder characterized by increased peripheral platelet destruction and reduced platelet production. Corticosteroids represent the standard first-line therapy achieving responses in around 80% of patients. However, for those corticosteroid-resistant ITP patients, who exhibit either no response (NR) to corticosteroids or corticosteroid-dependent, the pathogenesis remains poorly understood and the management is challenging. Emerging evidence from mouse studies has suggested that the cross-talk between megakaryocytes (MKs) and endothelial progenitor cells (EPCs) in the bone marrow (BM) microenvironment regulates MKs maturation and thrombopoiesis. We recently reported that the impaired BM EPCs, which could be quantitatively and functionally improved by atorvastatin in vitro, induced the occurrence of poor graft function following allo-transplant (***Blood****, 2016,128:2988-2999*). However, little is known about the functional role of BM EPCs and how to improve impaired BM EPCs in patients with corticosteroid-resistant ITP.
Aims: To determine whether quantitative and/or functional abnormalities of BM EPCs are involved in the occurrence of corticosteroid-resistant ITP. Moreover, to investigate the effects of atorvastatin and N-Acetyl-L-cysteine (NAC, a ROS scavenger) on the number and function of cultivated BM EPCs derived from patients with corticosteroid-resistant ITP and its underling molecular mechanisms. Finally, to evaluate the efficacy and safety of atorvastatin and NAC to adult patients with corticosteroid-resistant ITP.
Methods: Twenty-three patients with corticosteroid-resistant ITP, 30 patients with newly diagnosed ITP and 17 healthy donors (age 18-55) were enrolled from 2016 to 2017 at Peking University Institute of Hematology. BM EPCs were cultured as previous reported. Atorvastatin and NAC were administrated to the 5-day cultivated BM EPCs in corticosteroid-resistant ITP patients until tested on day 7. The number and function of BM EPCs were evaluated pre- and post-treatment by cell counting, DiI-Ac-LDL and FITC-lectin-UEA-1 double staining, migration, cell proliferation, tube formation, levels of reactive Oxygen Species (ROS) and apoptosis. Proteins expressions for p38, ERK, JNK, Akt were measured by flow cytometry and western blot. Subsequently, a single-center pilot study was performed to evaluate the efficacy and safety of atorvastatin and/or NAC in corticosteroid-resistant ITP patients. The primary end points were complete response (CR), response(R), and overall response (OR). Secondary end points were time to response (TTR) and adverse events.
Results: Human bone marrow EPCs were demonstrated as the spindle shape and the similar expression of CD34, VEGFR2 and CD133 at day 7 of cultivation among the enrolled three cohorts of subjects. Decreased and dysfunctional BM EPCs, which were characterized by impaired proliferation, migration, angiogenesis, and higher levels of ROS and apoptosis, were revealed in corticosteroid-resistant ITP patients compared to those in newly diagnosed ITP. Activation of p-P38 was detected in BM EPCs from corticosteroid-resistant ITP patients. Furthermore, the number and function of BM EPCs derived from corticosteroid-resistant ITP patients were enhanced by atorvastatin or NAC treatment *in vitro* through down-regulation of the p38 mitogen-activated protein kinase (MAPK) pathway. In the single-center pilot study, a total of 12 corticosteroid-resistant ITP patients were recruited to receive either the combination of atorvastatin and NAC or alone. As a result, the CR, R and OR rates were 25% (3/12), 41.7% (5/12) and 66.7% (8/12), respectively. In patients who achieved CR and R, the median (range) TTR was 24 days (7-51 days), with no apparent adverse events.
Summary/Conclusions: The number and the function of BM EPCs were impaired in corticosteroid-resistant ITP patients. Treatment with atorvastatin and NAC *in vitro* and *in vivo* quantitatively and functionally improved BM EPCs derived from corticosteroid-resistant ITP patients through down-regulation of the p38 MAPK pathway. Although the sample size of clinical study is small, with a relatively short follow-up period by now, our data suggest that atorvastatin and NAC are effective and safe in the management of corticosteroid-resistant ITP patients. Therefore, further prospective multicenter randomized clinical trials with larger sample size are needed in the future.

P726

PLATELET DESIALYLATION IS A NOVEL MECHANISM AND A THERAPEUTIC TARGET IN THROMBOCYTOPENIA DURING SEPSIS: AN OPEN-LABEL, MULTICENTER, RANDOMIZED CONTROLLED TRIAL

X. Li[1,*], M.-F. Li[2], X.-L. Li[2], S.-Y. Geng[3], L. Huang[4], M. Hou[1], L.-Y. Liu[2], J. Peng[1]
[1]Department of Hematology, Qilu Hospital, Shandong University, Jinan, China, Jinan, [2]Yantai Yuhuangding Hospital Affiliated to Qingdao University, Yantai, China, [3]Infectious Disease Hospital of Yantai, Yantai, China, [4]Yantaishan Hospital of Yantai, Yantai, China, Yantai, China

Background: Sepsis is a systemic, deleterious host response to infection leading to severe sepsis, and possibly septic shock as defined by the Surviving Sepsis Campaign guidelines. Thrombocytopenia is a common finding in sepsis. Studies in murine models suggested that platelet desialylation was an important mechanism of thrombocytopenia during sepsis. Desialylation-induced platelet removal could possibly be circumvented by adding sialidase inhibitors during sepsis. Oseltamivir, also known as Tamiflu, is a viral sialidase inhibitor that prevents the release of progeny virions. Several studies suggests the feasibility that oseltamivir can be used for the treatment of infection-associated thrombocytopenia.
Aims: To determine whether thrombocytopenia is associated with increased platelet desialylation in septic patients, and whether oseltamivir is an effective treatment to increase platelet counts in severe sepsis.
Methods: We first performed a prospective, multicenter, observational study that enrolled septic patients with or without thrombocytopenia to determine the association between platelet desialylation and thrombocytopenia in patients with sepsis. Next, we conducted an open-label, randomized controlled trial in which the patients who had severe sepsis with thrombocytopenia (platelet counts ≤50×10^9/L) were randomly assigned to receive antimicrobial therapy alone (control group) or antimicrobial therapy plus oseltamivir (oseltamivir group). The study flowchart is shown in Fig. 1. Both groups received appropriate antimicrobial agents and standard medical support based on the guidelines issued by the Surviving Sepsis Campaign. The oseltamivir group additionally received 5 full days of oseltamivir therapy. The oseltamivir was administered orally or through a feeding tube at a dose of 75mg once every 12 hours. Time from randomization to the administration of oseltamivir was less than 24 hours. The antimicrobial agents were continuously administered until 3 days after the resolution of the physiological abnormalities related to the systemic inflammatory response syndrome (SIRS). The primary outcomes were platelet desialylation level at study entry, and overall platelet response rate within 14 days post-randomization. Secondary outcomes included platelet recovery time, the occurrence of bleeding events, and the amount of platelets transfused within 14 days post-randomization**.** The percentages of platelets positive for *Ricinus communis* agglutinin I (RCA-I), *Erythrina cristagalli* lectin (ECL) or Succinyl *Triticum vulgare* lectin (sWGA) analyzed by flow cytometry represented the levels of platelet desialylation. Platelet response was defined as platelet counts returning to or above 100×10^9/L. Platelet recovery time was calculated as the date of randomization to the date when platelet counts were >100×10^9/L. Written informed consents were obtained from the study participants prior to inclusion in the study.

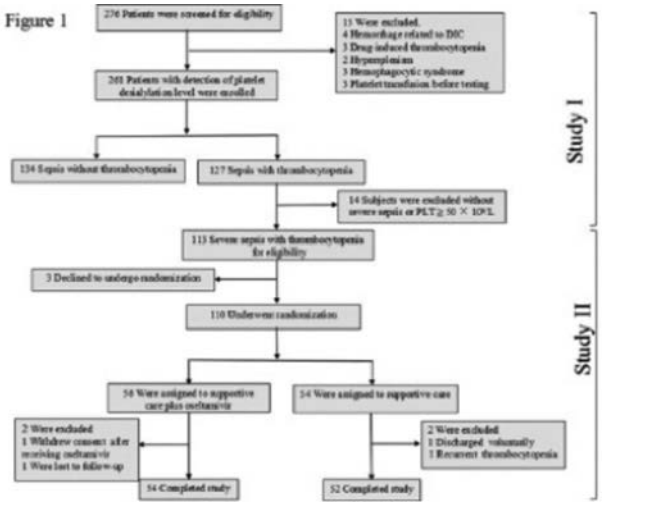

Figure 1.

Results: The platelet desialylation levels increased significantly in the 127 septic patients with thrombocytopenia compared to the 134 patients without thrombocytopenia. A platelet response was achieved in 45 of the 54 patients in the oseltamivir group (83.3%) compared with 34 of the 52 patients in the control group (65.4%; P=0.045). The median platelet recovery time was 5 days (interquartile range 4-6) in the oseltamivir group compared with 7 days (interquartile range 5-10) in the control group (P=0.003). The amount of platelets transfused decreased significantly in the oseltamivir group compared to the control group (P=0.044). The multivariate analysis by Cox proportional hazards models showed that the Sequential Organ Failure Assessment (SOFA) score and platelet recovery time were independent indicators of oseltamivir therapy.
Summary/Conclusions: Thrombocytopenia was associated with increased platelet desialylation in septic patients. The addition of oseltamivir could significantly increase the platelet response rate, shorten platelet recovery time and reduce platelet transfusion. Chinese Clinical Trial Registry, ChiCTR-IPR-16008542.

Background: Children with ITP for ≥6 months who completed a romiplostim phase 1/2 or phase 3 parent study could enroll in this open label long term extension study
Aims: To evaluate the safety and efficacy of long-term romiplostim in children with ITP.
Methods: Patients enrolled at 28 sites in the US, Canada, Spain, and Australia. All patients received SC romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg for patients previously receiving placebo; dose was then adjusted from 1-10 µg/kg to target platelet counts of 50−200×10^9/L. Incidence of adverse events (AEs) was the primary endpoint.

Remission cases	1	2	3	4	5	6	7	8	9
Age, years	18	10	13	8	5	7	7	5	5

B, black; Rx, therapy; W, white. * Still on study.

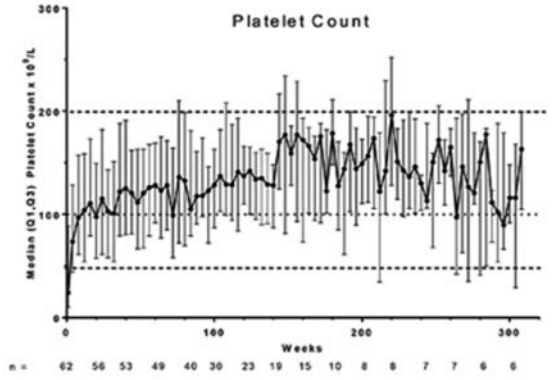

Figure 1.

Results: As of 24 Feb 2016, 66 patients entered this study; 65 received romiplostim for up to 6.2 years. At baseline, median (min–max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, 14% Hispanic/Latino, 9% Asian, and 3% other; 9.1% had prior splenectomy. Median (min–max) baseline platelet count was 27.5 (2–458)×10^9/L. Median (min–max) treatment duration was 100 (5–321) weeks. Median (min–max) average weekly romiplostim dose was 4.8 (0.1–10.0) µg/kg, which included escalation to a stable dose. After ~week 200 (n ≤8 patients), the median dose was observed to fluctuate. All 65 patients received their doses per protocol >90% of the time; 18 patients missed ≥1 dose due to noncompliance for a total of 41 times. Reasons for discontinuing treatment (n=22, 33%) included consent withdrawn (n=8), required other therapy (n=4), noncompliance (n=3), administrative decision (n=3), per protocol (n=1), and AE (n=2) (asthenia, headache, dehydration, and vomiting in one patient and anxiety in the other, per investigator, none of the AEs were treatment-related); 43 (65%) patients continued in the study. Fifty-two serious AEs occurred in 17 patients, 3 deemed treatment-related (anemia, epistaxis, and thrombocytopenia). Bleeding AEs occurred in 56 patients; 5 deemed treatment-related (gingival bleeding, petechiae, injection site bruising, injection site hematoma, and epistaxis). No thrombotic events were reported. There were no peripheral blood abnormalities warranting a bone marrow examination. No patients had anti-TPO neutralizing antibodies. From week 2 on, median platelet counts remained >50×10^9/L; platelet counts were >100×10^9/L at most timepoints, despite an observed decrease in the median dose from 4-5 µg/kg to 2-3 µg/kg around week 160 (Figure). Nearly all (94%, 61/65) patients had a platelet response (median platelet counts for a month ≥50×10^9/L). Nine (14%) patients (5 boys and 4 girls, none with prior splenectomy) entered remission (Table), defined here as platelet counts ≥50×10^9/L for 24 weeks with no ITP treatments. Twenty-three (35%) patients received rescue medications.
Summary/Conclusions: Over 6 years of data from this ongoing open-label extension study of romiplostim in children with ITP show that >90% of children achieved a platelet response with romiplostim. The safety profile was overall tolerable, similar to that in past studies. Some children (9/66) with longstanding ITP entered remission after receiving romiplostim.

Quality of life, palliative care, ethics and health economics 2

P728

IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF CLL PATIENTS RELAPSED/REFRACTORY TO B-CELL RECEPTOR (BCR) SIGNALING PATHWAY INHIBITOR TREATMENT

W. Wierda[1,*], K. Sail[2], J. Potluri[2], L. Noe[2], R. Kamalakar[2], J. Gdovin[2], R. Humerickhouse[2], M. Verdugo[2]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]AbbVie Inc, North Chicago, United States

Background: The prognosis for patients with CLL after B-Cell Receptor inhibitor (BCRi) failure is very poor. Patients with R/R CLL who discontinue and/or progress on BCRi treatment tend to have poor clinical outcomes. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.
Aims: To assess whether VEN has an impact on health related quality of life (HRQoL) among CLL patients R/R to BCRi treatment and receiving VEN monotherapy.
Methods: The study enrolled patients with CLL who had previously received treatment with ibrutinib and/or idelalisib, have relapsed on treatment, or experienced progression after discontinuation of either agent. Patients are to receive VEN monotherapy for up to two years, or until discontinuation due to disease progression, unacceptable toxicity, or any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), Week 24, and every 12 weeks thereafter. Mean change from BL to each assessment through Week 48 are reported here. Clinical relevance was based on minimum important difference (MID) of values from BL to each assessment. A change of 5-10 points is considered a "small" change on the EORTC-QLQ-C30. The lower bound of 5 points was used for MID acceptance on both measures.
Results: Clinically meaningful improvements from BL were observed early and were sustained through week 48 in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Furthermore, early and sustained improvements in fatigue through week 48 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (**Table 1**).

Table 1.

Table 1. Change from Baseline Results in Key Domains on EORTC QLQ-C30 and EORTC QLQ-CLL16

EORTC QLQ-C30 parameter (n)	BL Mean	Visit Mean	Mean Change from BL (95% CI)
Global Health Status[a]			
Week 24 (40)	62.9	75.0	12.1 (3.2, 20.9)
Week 48 (33)	64.1	71.0	6.8 (-1.7, 15.3)
Role Functioning[a]			
Week 24 (40)	74.2	87.9	13.8 (5.1, 22.4)
Week 48 (34)	77.5	91.7	14.2 (6.2, 22.2)
Social Functioning[a]			
Week 24 (40)	75.0	85.8	10.8 (2.7, 19.0)
Week 48 (34)	77.9	86.3	8.3 (0.7, 15.9)
Fatigue[b]			
Week 24 (40)	38.1	23.7	-14.3 (-21.1, -7.5)
Week 48 (34)	35.3	22.5	-12.7 (-21.0, -4.5)
EORTC QLQ-CLL16 parameter (n)	**BL Mean**	**Visit Mean**	**Mean Change from BL (95% CI)**
Fatigue[b]			
Week 24 (40)	35.4	20.0	-15.4 (-23.6, -7.2)
Week 48 (34)	33.3	20.1	-13.2 (-20.8, -5.7)

[a] A positive change in score represents improvement.
[b] A negative change in score represents improvement.

Summary/Conclusions: This interim analysis provides preliminary evidence that demonstrates CLL patients R/R to BCR inhibitors receiving VEN monotherapy experienced improvement in several key aspects of functioning and HRQoL. These results may be important to consider when making therapeutic choices in R/R CLL following relapse or progression on BCRi inhibitors.

P729

THE ROLE OF PSYCHOLOGICAL VARIABLES FOR TYROSINE KINASE INHIBITORS (TKI) DISCONTINUATION IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS: IMPLICATION FOR MEDICAL DECISION MAKING PRACTICE

S. Riva[1,*], A. Cortelezzi[2], I. Cutica[1], E. Orlandi[3], E. Chiara[3], C. Bucelli[2], A. Iurlo[2], G. Pravettoni[1]
[1]Department of Oncology and Hematology, University of Milan, [2]Hematology-BMT Unit, IRCCS Ca' Granda Policlinic Foundation Hospital, Milan, [3]Department of Oncology Hematology,, IRCCS Policlinic San Matteo Foundation Hospital, Pavia, Italy

Background: Treatment-free remission (TFR) is an emerging goal for CML patients (pts) that reach a sustained deep molecular response (DMR), as it can reduce the risk of long-term toxicities that impair quality of life, and mitigate the costs associated with long-term TKI therapy. Therapy discontinuation may represent a great challenge for patients and different factors (not only clinical) may play a role in medical decision, such as psychological and emotional variables. In this respect, it is essential to consider pts' concerns and preferences regarding the discontinuation option.
Aims: This study was aimed at investigating psychological (emotional and cognitive) and clinical factors related with the attitude to opt for discontinuation of therapy in CML pts.
Methods: This is an observational, prospective, no-drug related study conducted in 3 Italian centers with large experience in CML treatment. A detailed battery of questionnaires focusing on health behaviour, risk taking and personality was administered.
Results: One hundred and twenty pts were enrolled (56% males; mean age=50, SD=1.2). Median duration of the disease was 8 years (range 1-39y). 62/120 pts were receiving Imatinib first line. The idea of stopping TKI is appealing for the 81.6% of pts if there is a chance of long-term stable disease and a high probability of response upon restarting a TKI. Pts are more likely to stop their TKI if the risk of relapse is no more than 30% (% Mean=33.62; SD=33.46). Main worries related with the choice to stop TKI are fear of possible disease recurrence, (60.5%), fear of drug resistance if the disease relapses (44.5%) and fear to disappoint family or friends (26.9%). Older pts (>40 years) are more concerned about relapse and subsequent lack of response than younger (x^2=9.65, p=0.02). Finally, pts with higher *passive risk taking* attitude (who are more reluctant and undecided in everyday-life decisions) seemed to be more afraid to lose disease control in CML. ANOVA showed a significant difference between the two groups (F=5.46; p=.021).
Summary/Conclusions: Many studies have confirmed the feasibility and safety of stopping TKI therapy in selected pts, with the potential to drastically modify clinical practice in CML management in the next future. TKI discontinuation appears appealing and challenging at the same time for many CML pts. This study, for the first time, analyses how and when pts would consider this option including implications for health care providers in clinical practice, using both a clinical and psycho-cognitive perspective.

P730

BUDGET IMPACT ANALYSIS OF BIOSIMILAR RITUXIMAB (CT-P10) FOR THE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE 28 EU MEMBER STATES

F. Rencz[1,2,*], L. Gulácsi[1,2], P. Baji[1,2], M. Péntek[1,2], V. Brodszky[1,2]
[1]Department of Health Economics, Corvinus University of Budapest, [2]HTA Consulting Budapest, Budapest, Hungary

Background: In December 2016, the European Medicines Agency's Committee for Medicinal Products for Human Use has recommended granting marketing authorization to biosimilar rituximab (CT-P10) in all indications of the reference product, including chronic lymphocytic leukaemia (CLL). Compared to the originator rituximab, significant price reductions are expected offering a more affordable treatment option for CLL patients across Europe.
Aims: To assess the budget impact of the introduction of CT-P10 into the treatment of CLL in the 28 EU member states. Moreover, we provide an estimation for the number of additional CLL patients that can be treated with CT-P10 from the cost savings.
Methods: A budget impact analysis was performed to evaluate the one-year cost outcomes under two scenarios with and without the availability of CT-P10. The budget impact was calculated as the difference in costs between the two scenarios. For the major European markets, five-year cost savings were also estimated. Market uptake of CT-P10 was assumed to be 30%. A third party payer's perspective was adopted, and only drug costs were considered. Based on expert opinion, it was assumed that when CT-P10 is entering the market it will be at 50-70% of the official list price of originator rituximab in each country. Costs of administration and monitoring were not incorporated in the calculations, as it can be assumed that these are equal for the reference product and CT-P10. The initial number of patients treated with rituximab was estimated from IMS sales data on total annual consumption of originator rituximab in 2016. Other model parameters such as patients' average body surface area and treatment rate of rituximab among CLL patients, were derived from the published literature. One-way sensitivity analysis was undertaken to test the robustness of model assumptions.
Results: Over a one year time horizon, the cumulative budget impact of adopting CT-P10 is estimated to be €17.80 million in the 28 EU member states (30% discount in drug prices compared to the originator rituximab). Countries responsible for the majority of the cost savings are Germany (€4.06 million), Italy (€3.15 million), France (€2.41 million), Spain (€1.50 million), the UK (€1.34 million), Poland (€0.80 million), Austria (€0.66 million), the Netherlands (€0.59 million), Finland (€0.49 million) and Sweden (€0.43 million). If the cost savings were used to treat additional CLL patients with CT-P10, a total of 1,624 patients could be treated annually throughout Europe. The potential cost savings are in a direct correlation with the price and market uptake of CT-P10. Applying a 40% and 50% discount in drug prices compared to the originator rituximab, cost savings are projected to €23.73 and €29.67 million, from which further

2,526 and 2,706 CLL patients could be treated with CT-P10, respectively. Over five years, the total cost savings are expected to reach €29.81 million in Germany, €23.10 million in Italy, €17.65 million in France, €10.98 million in Spain and €9.83 million in the UK.
Summary/Conclusions: Biosimilar rituximab has the potential to improve the affordability of CLL treatments and easing the burden of healthcare costs in Europe. The cost savings might be even larger in case of a higher price discount for CT-P10. Using the cost savings to treat additional patients would substantially increase the access to better cancer medications, and thus contribute to a longer survival as well as better quality of life outcomes in CLL.

P731

AN INVESTIGATION INTO THE NEEDS AND PRIORITIES OF PATIENTS WITH MULTIPLE MYELOMA DURING REMISSION–IMPLICATIONS FOR RE-DESIGNING PATIENT-CENTRED HEALTHCARE SYSTEMS.
D. De-Silva[1,*], J. Land[2], M. Heinrich[2], J. Galinsky[3], Y. Reyal[4], N. Rabin[5], A. Mehta[5], K. Yong[1]
[1]UCL Cancer Institute, [2]Department of Behavioural Science and Health, University College London, London, [3]Myeloma UK, Edinburgh, [4]Haematology, St George's Hospital, [5]Haematology, University College London Hospital, London, United Kingdom

Background: Therapeutic advances in multiple myeloma (MM) mean that patients have extended periods of remission without need for active anti-myeloma therapy. This provides an opportunity to review how these patients are managed and design patient-centred healthcare systems. Remote monitoring systems have been implemented for other cancer patients in remission.
Aims: We aimed to explore patient needs during stable remission from MM and the influence of these on acceptability of remote monitoring.
Methods: Patients with stable MM in a treatment-free interval selected from outpatient clinics at a tertiary centre completed a survey which explored the acceptability of various methods of remote monitoring. Subsequently semi-structured interviews were conducted by an independent researcher to investigate factors influencing this preference. Interviews were carried out until saturation of themes, transcribed verbatim and thematic analysis was performed using open coding by a doctor, physiotherapist and psychologist.
Results: 78 patients were surveyed; the most acceptable alternative was a telephone clinic (with doctor 77%, nurse 69%). 19 interviews were conducted exploring suitability of a nurse-led telephone clinic (TC) replacing current face to face (FTF) consultations with a doctor. Median age was 61years (range 46-76), and 9 were male. 18 patients were in 1st remission; 16 had most recently received high dose therapy and autograft, 3 had post autograft consolidation. The centre was not the local hospital for 18 patients interviewed. The majority were accepting of TC as an alternative to FTF clinics due to the burden of travel, associated cost and clinic waiting times. These affected patients' physical and psychological well-being, with TC perceived as less burdening. Patients acknowledged reduced needs during remission compared to treatment phase and felt TC would benefit redistribution of consultant time for patients on active therapy. Some patients suggested this service change would be more beneficial for healthcare resourcing rather than them personally. Interpretation of blood results by clinicians was regarded as central to monitoring disease, and for some who were unaware of clinical symptoms, the only way a relapse would be detected. General preference was for bloods to be done locally, leading to concerns about availability of results for TC. Patients were unsure how to monitor their own MM, hence valued the knowledge of their medical team. Doctors were perceived to have more expertise than nurses and this influenced preferences regarding who undertook TC. As a result, patients sought reassurance they could see a doctor if they had any concerns after TC with a nurse. Patients valued continuity under the centre where they were treated due to prior positive experience and the importance of being seen at a tertiary centre renowned for its expertise in MM. This influenced acceptability of TC as long as they remained under the centre's care with preference for continuity of staff involved. Whilst TC was acceptable for patients in remission, some were concerned about how relapse would be managed and expressed preference for FTF when being told they had relapsed.
Summary/Conclusions: Nurse led TCs are an acceptable alternative to FTF consultations for monitoring patients in remission from MM. Design of healthcare systems incorporating TCs need to have robust systems for accessing blood test results, for managing relapse, ready access to doctors and reassurance about the competence and knowledge of practitioners involved.

P732

COST-EFFECTIVENESS OF RITUXIMAB IN ADDITION TO STANDARD OF CARE CHEMOTHERAPY FOR ADULT PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA
J. Nam[1], M. Geirnaert[2], R. Milenkovski[1], K. Paulson[3,4], S. Yunger[1], M. Seftel[3,4,*]
[1]Hoffmann-La Roche Limited, Mississauga, [2]Provincial Oncology Drug Program, [3]Haematology and Medical Oncology, CancerCare Manitoba, [4]Internal Medicine, University of Manitoba, Winnipeg, Canada

Background: In The Group for Research on Adult Acute Lymphoblastic Leukemia Rituximab (GRAALL-R) study, the addition of the anti-CD20 monoclonal antibody rituximab to standard chemotherapy for Philadelphia chromosome negative, CD20-positive, B-cell precursor Acute Lymphoblastic Leukemia (CD20+ Ph- BCP-ALL) resulted in improved clinical outcomes. However, the cost-effectiveness of rituximab for this indication has not been previously evaluated. We examined this question in the context of the Canadian publicly funded health care system.
Aims: To determine the economic impact in Canada of the addition of rituximab to standard of care (SOC) chemotherapy *vs* SOC alone in newly diagnosed CD20+ Ph- BCP-ALL.
Methods: Standard of care consisted of the two most widely used chemotherapy regimens for adults with ALL in Canada: hyper-CVAD or the Dana Farber Cancer Institute (DFCI) ALL consortium. A decision analytic model included the following health states over a 15-year time-horizon: event-free survival, relapsed/resistant disease, cure (death from causes other than ALL, given ≥5 years EFS) and death. Event-free survival, overall survival and serious adverse event (SAE) rates were taken from the GRAALL-R randomized controlled trial by Maury *et al.* Costs of the model included: first-, second- and third-line treatment and administration; disease management; palliative care; and SAE-related treatments. Model inputs were sourced from public data, literature and provincial cancer agency input. Results are presented using probabilistic sensitivity analysis and Monte Carlo simulation incorporating uncertainty around all model inputs.
Results: Life years increased by 1.33 years (95%CI: 0.10-2.63 years) with rituximab in addition to SOC *vs* SOC alone. Quality-adjusted life-years (QALYs) increased by 1.15 QALYs (95%CI: 0.34-1.93 QALYs) with rituximab in addition to SOC. The incremental cost of rituximab plus SOC was C$46,624 (95%CI: C$28,881-C$64,515), chiefly due to the drug acquisition costs of rituximab. Superior relative EFS associated with rituximab in addition to SOC drove lower second-line treatment and palliative care use, resulting in modest cost savings. The resulting mean Incremental Cost-Effectiveness Ratio (ICER) was C$40,505/QALY. At a willingness-to-pay threshold of C$100,000/QALY, the probability of being cost-effective was 96%. Decision outcomes were robust to the probabilistic and deterministic sensitivity analyses, including the SOC backbone as either hyper-CVAD or DFCI.
Summary/Conclusions: For adults with CD20+ Ph- BCP-ALL, rituximab in addition to SOC is a cost-effective intervention compared to SOC alone, from a Canadian public payer perspective. Rituximab is associated with increased life years and increased QALYs at a reasonable incremental cost.

P733

THE THERAPEUTIC UTILITY OF A SYSTEMATIC PROTOCOL FOR GERIATRIC ASSESMENT IN ONCOHEMATOLOGIC PATIENTS
C. Terán [1,*], A. Hormigo [2], R. Cordoba [1], M. Jarana[3], M. Perez[3], C. Plaza[3], P. LLamas[1]
[1]Hematology, [2]Geriatrics, [3]Oncohealth, Fundacion Jimenez Diaz, Madrid, Spain

Background: The prevalence of hematological malignancies has increased overtime especially in the older population. In the era of immunochemotherapy and targeted therapy, it is important to have a multidimensional and comprehensive assessment that allows the identification of those subsidiaries to intensive therapeutic measures or a more conservative approach. To choose the best treatment for these patients, a geriatric hematology program has been launched.
Aims: Evaluate the utility of the comprehensive geriatric assessment (CGA) in patients with hematologic malignancies on the initial therapeutic decision making. Determine frailty prevalence and short - mid term prognostic impact using a screening tool for its identification.
Methods: Patients diagnosed with hematological malignancies were followed prospectively. Patients age 70 and over were referred to hematological nursing consultation. G8 screening tool was used to identify frailty risk. Patients with G8 score <14 were referred for a complete medical consultation in Geriatric Oncology Clinic for carrying out the CGA. In the comprehensive geriatric assessment, the clinical information obtained included: physical, mental, social and nutritional assessments, as well as an additional screening on geriatric syndromes. The regular medication was reviewed based on the **STOPP/START** criteria. The patients were classified in 3 categories according to the ***Balducci*** classification: 1) **Fit,** 2) **Fragile** and 3) **Poor prognostic**.
Results: We have included 32 patients in the last 9 months, with an average age of 81 (71-89) years. 56% of the sample was female. The main hematological malignancy referred was high grade non-Hodgkin lymphoma (59%). At the time of the evaluation, 87% had ECOG 1 and 56% EuroQoL score of 80. The social, functional and mental profiles are shown in Table 1. According to polipharmacy and comorbidities, data are shown in Table 2. The distribution of patients by frailty scales, are described in Table 3. 56% of the patients were classified as robust, 35% fragile and the rest with poorly prognosis**.** After the evaluation we recommended nutritional measures, control of the polypharmacy and physical exercise. Of the included patients, 22 had been reviewed at 6 months staying alive 95%. 24% required hospitalization after the initial assessment and 13% went to the emergency department.

Tables.

Table 1.

BARTHEL	LAWTON	FAC	GDS	SOCIAL
56% independent. 34% mild dependence.	80% <4 advanced activities.	80% independent walk.	90% do not have cognitive impairment	90% had social support.

Table 2.

CHARLSON	CIRS	>5 DRUGS	>3 diagnostics in addittion to oncological
56% high comorbidity rate.	11.25 on average.	75%	34,3%

Table 3.

FRAIL	SPPB
61% was not fragile	83% had mild or no limitation.

Summary/Conclusions: Our population had a high score of comorbidity and polypharmacy with a high median age. Nevertheless, 9% of the patients benefited from the treatment. In 34% of the cases, the treatment was adjusted because of the frailty criteria. 95% were alive and without clinical impairment. All these findings support the importance of the comprehensive geriatric assessment in the inicial evaluation of elderly patients with hematological malignancies.

P734

RADIATION EXPOSURE FROM CT IMAGING AND CHILDHOOD LEUKEMIA: A NATIONWIDE CASE-CONTROL STUDY

A. Nikkilä[1,*], J. Raitanen[2,3], O. Lohi[4], A. Auvinen[2,4,5]
[1]Faculty of Medicine and Biosciences, [2]Faculty of Social Sciences, University of Tamepre, [3]UKK Institute for Health Promotion, [4]Tampere Center for Child Health Research, Tampere University Hospital and University of Tampere, Tampere, [5]STUK - Radiation and Nuclear Safety Authority, Helsinki, Finland

Background: Pediatric CT imaging offers significant benefits in clinical practice. However, children are more sensitive to carcinogenic effects of ionizing radiation than adults and red bone marrow is especially radiosensitive tissue type. The risk estimates of low doses of ionizing radiation are mainly[1,2] based on extrapolated results of studies done with substantially higher radiation doses and there exists a need to assess the risks of low doses with a more direct approach.
Aims: We assessed the leukemia risk in children after computed tomography imaging studies with high-quality Finnish register data and data from hospital databases.

Table 1.

Table Odds ratios and frequencies of CT scans

	Cases	Controls	TOTAL	
CT scans				**OR *(95% CI)***
0	1043	3268	4311	
1	5	7	12	*2.78 (0.73, 10.5)*
2 or more	5	2	7	*16.9 (1.91, 150)*
1 or more	10	9	19	*4.75 (1.55, 14.5)*
by type				
ALL	8	6	14	*6.50 (1.66, 25.5)*
others	2	3	5	*2.03 (0.25, 16.5)*
by age-group				
2 - <7yo	3	1	4	*9.00 (0.94, 86.5)*
7 - <15yo	8	7	15	*1.69 (0.99, 9.09)*

The reference group for all calculated ORs is zero CT scans.

Methods: We used nationwide, register-based case-control study design to investigate the role of CT imaging in the etiology of childhood leukemia. We identified all childhood (0-15 years) leukemia cases from 1990 to 2011 (N=1093) in Finland and randomly selected thrice as many controls (N=3279) from the Population Registry, individually matched by gender and year of birth. The cases were 81% (N=885) acute lymphoblastic leukemias and 13% (N=142) acute myeloid leukemias. We collected data on all pediatric CT scans from 1975–2011 from the databases of all five university hospitals in Finland and two large central hospitals. In total, we identified 46 CT scans to our subjects. We approximated that this approach covers 81% of all pediatric CT scans performed in Finland from 1975 to 2011. We used a two-year latency period to avoid reverse causation. Conditional logistic regression analyses were adjusted for birth weight (large for gestational age) to control confounding. Cases with Down syndrome were excluded from the analyses.
Results: Overall, 13 cases (1.2%) and nine controls (0.3%) had a record indicating at least one CT examination. Of the relevant CT scans, 50% were performed on the head region and 41.3% the thorax region. The median age at CT scan was 8.12 years (7.46 years for cases and 10.0 years for controls).
In a conditional logistic regression analysis adjusted for birth weight, a significantly increased leukemia risk (OR=4.75, 95% CI 1.55, 14.5) was found for any CT examination (one or more) at least two years prior to leukemia diagnosis. When comparing one CT examination and two or more CT examinations with no examinations the ORs were respectively 2.78 (95% CI 0.73, 10.5) and 16.9 (95% CI 1.91, 150).
Summary/Conclusions: In our preliminary analyses we observed a substantial increase in childhood leukemia risk related to pediatric CT scans. The risk estimates are materially higher than in two earlier studies[1,2] and need to be interpreted with caution. We will seek to estimate radiation doses to the red bone marrow, based on limited data available on CT examinations (body part and examination type).

HEALTHCARE RESOURCE UTILIZATION WITH IXAZOMIB OR PLACEBO PLUS LENALIDOMIDE-DEXAMETHASONE IN THE RANDOMIZED, DOUBLE-BLIND, PHASE 3 TOURMALINE-MM1 STUDY IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

P. Hari[1,*], H.M. Lin[2], Y. Zhu[2], D. Berg[2], P. Richardson[3], P. Moreau[4]
[1]Medical College of Wisconsin, Milwaukee, [2]Millennium Pharmaceuticals Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [3]Dana-Farber Cancer Institute, Boston, United States, [4]University Hospital Hôtel Dieu, Nantes, France

Background: Treatment paradigms for RRMM have evolved in recent years with the approvals of multiple novel agents and evidence of benefits for using triplet *vs* doublet therapy and continuous treatment until progression. With more complex regimens and longer treatment duration, costs of treatment and healthcare resource utilization (HRU) are expected to increase, with IV agents having a greater impact on treatment burden than oral agents. The oral proteasome inhibitor ixazomib is approved in the US, EU, and multiple countries worldwide, in combination with lenalidomide-dexamethasone (Rd), for the treatment of RRMM patients (pts) following at least 1 prior therapy. Approval was based on the phase 3 TOURMALINE-MM1 study of ixazomib-Rd *vs* placebo-Rd, which demonstrated significantly improved progression-free survival (PFS; median 20.6 *vs* 14.7 months, HR 0.74) with ixazomib-Rd, with limited additional toxicity and no adverse impact on patient-reported quality of life (QoL; Moreau et al, N Engl J Med 2016).
Aims: HRU was an exploratory endpoint of the TOURMALINE-MM1 trial. The aim of this analysis was to compare HRU with ixazomib-Rd *vs* placebo-Rd, incorporating all non-protocol additional medical care encounters such as inpatient and outpatient admissions and their duration, as well as time lost from work or other activities by pts and their caregivers.
Methods: 722 RRMM pts with 1-3 prior lines of therapy received ixazomib 4mg (n=360) or matching placebo (n=362) on days 1, 8, and 15, plus lenalidomide 25mg on days 1-21 and dexamethasone 40mg on days 1, 8, 15, and 22, in 28-day cycles until disease progression or unacceptable toxicity. The primary endpoint was PFS. HRU was assessed on day 1 of each cycle prior to treatment and every 4/12 weeks during PFS/overall survival follow-up. After a median follow-up of ~23 months, pts had received a median of 17 (range 1-34) and 15 (1-34) cycles of ixazomib-Rd and placebo-Rd, respectively; HRU data are reported from this analysis time point.

Table 1.

Table 1	Ixazomib-Rd (n=360)		Placebo-Rd (n=362)	
Hospitalizations	**Rate ppy (95% CI)**	**Mean length, d**	**Rate ppy (95% CI)**	**Mean length, d**
Any	0.530 (0.471, 0.588)	10	0.564 (0.503, 0.624)	10.8
Acute care unit	0.411 (0.359, 0.462)	6.3	0.463 (0.408, 0.517)	8.2
Palliative care unit	0.069 (0.048, 0.090)	1.3	0.062 (0.042, 0.082)	1.6
Intensive care unit	0.034 (0.019, 0.048)	1.1	0.024 (0.011, 0.036)	0.4
Hospice care	0.022 (0.010, 0.034)	1.2	0.029 (0.015, 0.042)	0.5
Outpatient visits	**Rate ppy (95% CI)**		**Rate ppy (95% CI)**	
Any	3.305 (3.159, 3.451)		3.355 (3.208, 3.502)	
ER	0.143 (0.112, 0.173)		0.109 (0.083, 0.136)	
Study physician	0.889 (0.813, 0.964)		0.939 (0.861, 1.017)	
Other physician/clinic	1.677 (1.573, 1.781)		1.810 (1.702, 1.918)	
Lab	0.037 (0.021, 0.052)		0.032 (0.018, 0.046)	
Radiology/biomedical imaging	0.179 (0.145, 0.213)		0.207 (0.170, 0.244)	
Other	0.589 (0.527, 0.650)		0.436 (0.383, 0.489)	

Ppy, per patient-year

Results: Overall, 152 (42%) pts on the ixazomib-Rd arm had 316 hospitalization events, compared to 156 (43%) pts (335 events) on the placebo-Rd arm. Exposure-adjusted hospitalization rates (0.530 and 0.564 per pt-year [ppy], respectively) and mean length of stay (10 and 10.8 days) were similar between the ixazomib-Rd and placebo-Rd arms (Table 1). Rates of outpatient visits were also similar between arms; 217 (60%) pts on the ixazomib-Rd arm had 1971 visits (median 4) compared to 198 (55%) pts and 1994 visits (median 5) on the placebo-Rd arm. Exposure-adjusted outpatient visit rates were 3.305 and 3.355 ppy, respectively (Table 1). On the ixazomib-Rd arm, 46 (13%) pts missed a total of 527 (median 7) days of work or other activity, compared to 51 (14%) pts and 580 (median 8) days on the placebo-Rd arm. Similarly, 16 (4%) pts' caregivers missed 128 (median 5) days of work or other activity on the ixazomib-Rd arm, compared to 24 (7%) pts' caregivers and 110 (median 4) days on the placebo-Rd arm.
Summary/Conclusions: The ixazomib-Rd triplet regimen did not add to the HRU burden compared to the placebo-Rd doublet, while prolonging PFS. These findings are consistent with the limited additional toxicity burden and the reported lack of an adverse impact on QoL with ixazomib-Rd. In contrast to findings reported for injected agents (Armoiry et al, J Clin Pharm Ther 2011; Gaultney et al, J Clin Pharm Ther 2013; Baz et al, Support Care Cancer 2015), this all-oral triplet regimen did not increase time lost from work, caregiver burden, or the number of inpatient/outpatient visits.

P736

MANAGEMENT, ECONOMIC AND SOCIAL IMPACT OF SUB-CUTANEOUS RITUXIMAB ADMINISTRATION IN LYMPHOPROLIFERATIVE MALIGNANCIES
V. Tomarchio[1], M.A. Surano[2], M.A. Tafuri[3], M. Becilli[3], C. Sarlo[3], P. Berti[3], S. Ferraro[3], R. Proietti[2], G. Tafuro[4], A. Bolettieri[5], D. Ioele[6], D. Tassielli[6], G. Scerbo[6], O. Annibali[1,*]
[1]UOC Ematologia Trapianto di Cellule Staminali, University Campus Biomedico, rome, [2]Area di Infermieristica, [3]UOC Ematologia Trapianto di Cellule Staminali, Università Campus Biomedico, [4]Area di Controllo e Gestione, [5]Area dei Sistemi Informativi, [6]Area Farmacia, Policlinico Universitario Campus Bio medico, Roma, Italy

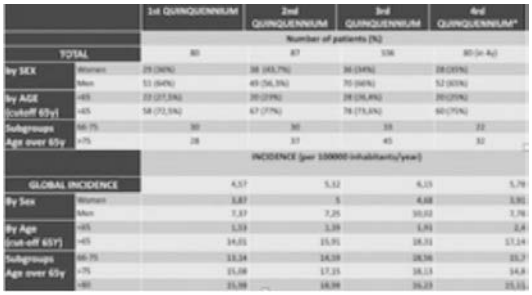
Background: Lymphoproliferative disorders (LD) represent a major burden of hematologic malignancies generally treated and followed in Hematological Day Hospital (DH). Diffuse Large B-Cell Lymphoma (DLBCL) and Follicular Lymphoma (FL) are among the most frequent LD treated with chemo-immunotherapies. These therapies are time consuming and costing and may affect the Quality of Life (QoL) of these patients because of their prolonged stay in DH.
Aims: To evaluate, in patients with DLBCL and FL, the economic and social impact of subcutaneous Rituximab administration.
Methods: From March 2016 to December 2016, we investigate in DLBCL and FL, the management advantages of subcutaneous rituximab administration compared to the intravenous formulation. During one week we evaluate in 40 patients the time of intravenous and subcutaneous administration, the type of treatment (rituximab combined or subsequent to chemotherapy, or in monotherapy) and the time required by the pharmacy to prepare each formulation. Moreover, we collected and analyzed data about patients' time expenditure in DH until discharge. Collected data have been categorized as follows: time and human resource employment; drug waste; safety for patient. In order to measure the effect on QoL of subcutaneous formulation, we administered a questionnaire of satisfaction to the patients affected by DLBCL and FL, and their 40 caregivers. Furthermore, we evaluated its role in the optimization of DH management in terms of time, professionals and economic expenditure and in improving patients' safety.
Results: Among the 40 patients, 55% were affected by DLBCL and 45% by FL, 64% were males and 36% females; as for age 68% were over 60 years. The questionnaire examined patient's emotions and perceptions during rituximab administration (anxiety, fear and pain), time required for infusion and interference with daily activities. Overall, 98% of interviewed patients preferred subcutaneous administration because less scared by this formulation and because of the lower waste of time. Among the 40 interviewed caregivers 68% were workers. They considered advantageous the subcutaneous formulation because of the lower waste of time (90%) and the reduced number of workdays lost (80% of workers). With the subcutaneous formulation, we observed a reduction of 38% (equal to 17.5 hours) of time spent at hospital per cycle. However, nurses needed 23% lesser time to handle a patient per cycle (from 144 minutes to 111 minutes), earning 33 minutes/patient per cycle. Furthermore, pharmacy spent 53% lesser time for drug preparation (from 40 minutes to 19 minutes), earning 21 minutes/patient per cycle. Finally, we observed a reduction of clinical risk. As for the cost, using subcutaneous formulation, we saved €254.25 for each dose, with a final saving of €61.021 in a year. Considering that patients who underwent subcutaneous administration of rituximab did not require DH admission, we saved additional for €24.000 for 2016, and caregivers spared 112 work days.
Summary/Conclusions: Our investigation shows that subcutaneous formulation of rituximab requires a lower psychological effort for both patients and caregivers because of a reduced time of administration. In addition, it reduces healthcare professionals and pharmacist's workload, ensures a major safety for patients, and allows an optimized use of DH armchairs. This brings to an increased satisfaction of patients and caregivers. Moreover, the costs analysis demonstrates a significant spending reduction improving planning of therapy sessions and organization.

P737

EFFECT OF IMPROVEMENTS OF SURVIVAL, POPULATION AGING AND IMWG´14 CRITERIA ON INCIDENCE AND PREVALENCE OF MULTIPLE MYELOMA
V. Martínez-Robles[1,*], B. Ballina[1], S. Cerdá[1], N. de las Heras[1], M. Fuertes[1], L. Villalobos[1], J.A. Rodríguez-García[1], E. Fernando[1]
[1]Hematología, Complejo Asistencial Universitario de León, LEON, Spain

Background: There are some variables that can modify Multiple Myeloma incidence of New Diagnosed (NDMM) and prevalence over the time: Past decade shows a new demographic data in our society: the increment of expectancy of life and an excellent performance status. In the last years we have assisted to an amazing improvement in the management and expectancy of life of Multiple Myeloma (MM) patients. Recent changes in criteria recommendation by IMWG´14 to begin treatment in NDMM patients can increment its incidence. New expensive but very effective and well tolerated antimyeloma (antiMM) agents are in the center of attention of Hematologic and Public Healthcare Systems. There are data of improvement of survival that can increment of prevalence.
Aims: We have analysed our data base and calculate incidence by sex, age and three 5-years periods of time at diagnosis and obtain tendencies to get ready for next decade of ageing people with best antimyeloma agents. We have analysed prevalence of MM patients on last 7 years with cutoff date on 1st of November (2010 to 2016).
Methods: We retrospectively analysed the incidence of patients with new diagnostic of Multiple Myeloma (NDMM) from 1998 to 2012. (Fig.1). Then we divide the cohort in several groups: sex and age at diagnosis (3 groups: <65, 66-75 and 75y) and in four 5-year (quinquennium) period of time (1998-2002, 2003-07, 2008-12, 2013-NOV2016). (Fig. 2). We have calculated the incidence per 100000 inhab/year using census data of our Local Registry of Tumours of our Public Health Area. Characteristics of patients: n= 346. M/F: 206/140. Median age at diagnosis: 74 years (Range: 39-100).
Results: A) INCIDENCE RATES (*see Table*). In the past IMW (Roma-14#PO197) we reported incidence rates form 1998 to 2012. We observed a constant increase of Annual Average of incidence from 4.57 cases/100000 inhabitants/ year from the 1st period to 6.15 in the last. Adjusted by Age Incidence also increase from 14 to 18.5 cases in the O65 group. From 2013 to Nov-2016 global and adjusted by age incidence remains similar to last years data with 80 new cases in the 4 year-period (5,9 cases for global population and 17,2 cases for over65 population). After IMWG´14 criteria to begin treatment in NDMM the incidence was similar to the last 7 years (2008-12 period plus 2013-14) Incidence with 37 NDMM cases (25 O65y group).
B) PREVALENCE RATES (PrevR):
• 2010. 74 patients alive. PrevR: 21.25 /100000 inhabit;
• 2012. 77 pats alive. PrevR: 22.2 /100000 inhabit;
• 2014. 84 pats alive. PrevR: 24.4/100000 inhabit;
• 2016. 103 pats alive. PrevR: 30.3 / 100000 inhabit.

Table 1.



Summary/Conclusions: Although we don´t observe substantial changes on incidence rates of NDMM, we have noted an important rise on prevalence rates of more than 40% from 2010 to 2016 (21.2 to 30.3 pats alive /100000 inhabit.) Several new antiMM drugs are available in the therapeutic arsenal and probably increases the prevalence rates.

Stem cell transplantation - Clinical 2

Ospedale Pediatrico Bambino Gesù, Roma, Italy

Background: Although most children affected by Acute Lymphoblastic Leukemia (ALL) are cured with current protocols, relapses still occur in the bone marrow as well in extramedullary sites, mainly the central nervous system (CNS) and the testis.
Aims: Optimal treatment for isolated extramedullary relapse (iEMR) is still controversial. To address this issue, we collected data of patients treated with hematopoietic stem cell transplantation (HSCT) for ALL iEMR from 19 centers, members of the Italian Pediatric Onco-Hematology Association (AIEOP).
Methods: From 1990 to 2015, 281 children (1-18 years) underwent HSCT for ALL iEMR in Italy. Informed consent was obtained from parents or legal guardians. Treatment protocols were based on Berlin-Frankfurt-Münster (BFM) Study Group concept, as well as definitions of iEMR, CNS relapse, and time of relapse (very early/ early/ late). HSCT was performed in second complete remission (CR2) or subsequent remission (CR>2), even patients transplanted with disease were included in the analysis. If a matched familiar (MFD) or a matched unrelated donor (MUD) was available, HSCT was performed from one of these; if not, the single center decided to perform autologous HSCT (Auto HSCT) or haploidentical HSCT (Haplo HSCT).
Results: Of the 281 patients (203 male, 78 female) 167 presented relapse confined to CNS, 73 to testis, 14 to mediastinum,11 to CNS + other sites and 18 to other organs. Thirty one percent of children experienced a late relapse, 34.5% an early relapse, 31% a very early relapse, for 3.5% the time of relapse is not known. Ninety-seven patients underwent auto HSCT, 79 MFD HSCT, 75 MUD HSCT and 30 Haplo HSCT. At transplantation 72.6% of children were in CR2, 21.0% in CR>2 and 6.4% were not in remission Total body irradiation (TBI) was part of 83.6% of conditioning regimens. Overall survival (OS) for the entire cohort was 56% at 10 years and was not influenced by sex, lineage, age, site of relapse, length of first remission, HSCT type (Auto *vs* MFD *vs* MUD *vs* Haplo). Patients transplanted in CR2 had the better OS (64%), those in CR>2 showed an OS of 44%, those transplanted with disease had an OS of 11% (p<0.0001). For HSCT performed before 2000 the OS was 45%, after 2000 was 63% (p 0.0009). TBI containing regimen yielded a better OS (59%) then regimens without TBI (40%) but this difference was not statistically significant (p 0.069). TRM for the entire cohort was 10% at 100 days, 11% at 6 months and 1 year and 16% at 10 years, with no difference between HSCT types. Multivariate analysis was conducted after exclusion of patients with active disease at HSCT: the only factors influencing outcome were number of CR and year of transplantation. Patients in CR>2 have a risk of death 2.3 times greater than those in CR2. Children treated after 2000 have half the risk of death then those treated from 1995 to 2000.
Summary/Conclusions: In this study we present the largest series of patients with ALL iEMR treated with HSCT with a very long follow up. Comparison with published chemo/radiotherapy approaches is favorable, especially for early and very early relapse: in fact the use of HSCT seems to abrogate the impact of some "classical" negative risk factors. Our results suggest that both autologous and allogenic HSCT are efficient treatments for ALL iEMR. Data from contemporary treatment protocols, that include MRD assessment to better stratify the patients, will further clarify the role of HSCT in the treatment of extramedullary relapses.

P739

PREDICTIVE FACTORS FOR DEVELOPING VENO-OCCLUSIVE DISEASE IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH INOTUZUMAB OZOGAMICIN FOLLOWED BY ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

P. Kebriaei[1,*], R. Saliba[1], W. Wallis[2], R. Garris[3], C. Ledesma[1], G. Rondon[1], U. Popat[1], A. Alousi[1], S. Ahmed[1], B. Oran[1], E. Shpall[1], S. Ciurea[1], F. Ravandi[3], K. Rezvani[1], D. Marin[1], R. Champlin[1], H. Kantarjian[3], E. Jabbour[3]
[1]Stem Cell Transplantation and Cellular Therapy, [2]Pharmacy Clinical Programs, [3]Leukemia, University of Texas M.D. Anderson Cancer Center, Houston, United States

Background: Inotuzumab ozogamicin (IO) is a CD22 monoclonal antibody attached to calicheamycin and targets B lymphocytes in early stages of development. In a randomized study of IO compared with conventional salvage therapy in patients with refractory relapsed B-ALL, patients treated with IO had higher complete response rates (81% *vs* 29%, p<0.001), and a greater proportion of patients proceeded to allogeneic hematopoietic stem cell transplantation (SCT) (41% *vs* 11%, p<0.001). However, patients treated with IO prior to SCT were also noted to have higher rates of veno-occlusive disease (VOD) compared to the SCT group without IO exposure (11% *vs* 1%) (Kantarjian NEJM 2016).
Aims: In efforts to further investigate this finding, we reviewed transplant outcomes for patients with and without IO exposure.
Methods: We performed a nested control comparison of patients transplanted during the years when they were being treated with IO on a number of clinical trials at our institution.
Results: Between 6/2010 and 10/2016, 251 patients with B-ALL with a median age of 35 years (range, 4-70 years) received an allogeneic matched sibling (n=85), matched- or 1-antigen mismatched unrelated (n=90), haplo-identical (n=38), or cord blood donor SCT (n=38) in CR1 (n=103), CR2+ (n=105), or with active disease (n=43). Patients received largely myeloablative regimens (82%) that were busulfan- (64%), fludarabine- (29%) or total body irradiation-based (TBI) (7%). 19% of patients received double alkylator regimens consisting of cyclophosphamide-TBI, fludarabine-melphalan-thiotepa, or busuflan-clofarabine-thiotepa. IO was administered to 69 (27%) patients prior to SCT. A median of 3 cycles of IO were administered (range, 1-5 cycles) at a median of 35 days from SCT (range, 11-254 days). Patients were heavily pre-treated, including 18 who had a prior allogeneic SCT. VOD was noted in 21 patients overall (8%) with median onset 19 days following SCT (range, 7-230 days); fatal VOD was noted in 5 patients (2%). VOD was noted in 11 patients treated with IO (16%), and it was fatal in 2 patients (3%). Factors noted to be significant in contributing to VOD in univariate analysis were prior exposure to IO (HR 3.05, 95% C.I. 1.3-7.2, p=0.01) and receiving a busulfan-based transplant preparative regimen (HR 3.4, 95% C.I. 1.02-12, p=0.05); not receiving a prior SCT was significantly protective (HR 0.3, 95% C.I. 0.1-0.8, p=0.02). Number of IO cycles, time from IO to SCT, age, and donor relation were not found to be significant factors for developing VOD. In efforts to predict the risk for VOD in a patient who has received prior IO, we performed a classification and regression tree analysis (CART) and noted that the combination of IO and a double alkylator preparative regimen was significantly associated with the risk for developing VOD (HR 5.9, 95% C.I. 1.9-18, p=0.002).
Summary/Conclusions: Fatal VOD is a rare occurrence. However, IO exposure prior to SCT increases the risk for any VOD. Furthermore, IO exposure followed by a double alkylator preparative regimen increases this risk nearly 6-fold, and should be avoided in these patients.

P740

DEFIBROTIDE EFFICACY AND SAFETY IN PATIENTS WITH HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME (VOD/SOS) DIAGNOSED AFTER DAY 21: ANALYSIS OF FINAL DATA FROM AN EXPANDED-ACCESS PROGRAM

P. Richardson[1,*], A. Smith[2], B. Triplett[3], N. Kernan[4], S. Grupp[5], J. Antin[6], L. Lehmann[7], S. Giralt[8], R. Ryan[9], R. Hume[9], W. Tappe[9], R. Soiffer[7]
[1]Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [2]Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, [3]Bone Marrow Transplantation and Cellular Therapy, St. Jude Children's Research Hospital, Memphis, [4]Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, [5]Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, [6]Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, [7]Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [8]Memorial Sloan-Kettering Cancer Institute, New York, [9]Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: Hepatic VOD/SOS is a potentially life-threatening complication of conditioning for hematopoietic stem cell transplant (HSCT). VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Although VOD/SOS typically begins <21 days post-HSCT (per Baltimore/modified Seattle criteria), late-onset VOD/SOS has been reported in 15%>20% of cases, sometimes after hospital discharge. The European Society for Blood and Marrow Transplantation (EBMT) proposed new criteria for adults including late-onset VOD/SOS (>21 days post-HSCT) by Baltimore criteria, histological evidence of VOD/SOS, or a version of Baltimore criteria using ≥2 of: bilirubin

≥2mg/dL, painful hepatomegaly, weight gain >5%, or ascites—***plus*** mandatory hemodynamic/ultrasound evidence of VOD/SOS. Defibrotide (DF) is approved to treat severe hepatic VOD/SOS post-HSCT in the EU, and for hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the US.
Aims: This is an analysis of DF efficacy and safety in patients (pts) with late-onset VOD/SOS using final data from an expanded-access study.
Methods: The original expanded-access protocol required VOD/SOS per Baltimore criteria or biopsy by Day+35 post-HSCT, with MOD (renal/pulmonary) by Day+45. The study was amended to include pts with later-onset VOD/SOS, with or without MOD; VOD/SOS per modified Seattle criteria; and VOD/SOS after chemotherapy alone. Pts provided informed consent and received DF 25mg/kg/d (6.25mg/kg q6h) for a recommended ≥21 days. "Late-onset" in this post-hoc analysis was defined as diagnosis >21 days post-HSCT; hemodynamic/ultrasound data (EBMT criteria) were not available.
Results: Of 1000 HSCT pts with a confirmed diagnosis of VOD/SOS and receiving ≥1 dose of DF, 264 (26.4%) had late-onset VOD/SOS, of whom 139 (52.7%) had MOD. By age group, 95/264 (36.0%) were pediatric (aged ≤16 years; 51/95 [53.7%] with MOD) and 169/264 (64.0%) were adults (aged >16 years; 88/169 [52.1%] with MOD). Kaplan-Meier estimated survival at Day +100 (**Figure**) was 52.8% (95% CI, 46.5%–58.7%) across all HSCT pts and 43.9% (95% CI, 35.4%–52.0%) for pts with MOD; for pediatric pts, this was 60.4% (95% CI, 49.5%–69.7%) overall and 45.4% (95% CI, 31.0%–58.6%) for pts with MOD; for adults, Day +100 survival was 48.7% (95% CI, 40.9%–56.0%) overall and 43.0% (95% CI, 32.5%–53.0%) for pts with MOD. Adverse events (AEs) occurred in 75.4% of the total group (80.6% with MOD); 70.5% of pediatric pts (76.5% with MOD); 78.1% of adults (83.0% with MOD). Treatment-related AEs (TRAEs) occurred in 20.8% overall (23.7% in those with MOD); 21.1% of pediatric pts (23.5% with MOD); 20.7% of adults (23.9% with MOD). The most common TRAEs (>3%) were epistaxis, pulmonary hemorrhage, gastrointestinal hemorrhage, and hematuria (each in <5% of pts). For TRAEs leading to study discontinuation (n=25) or death (n=10), the most common was pulmonary hemorrhage.

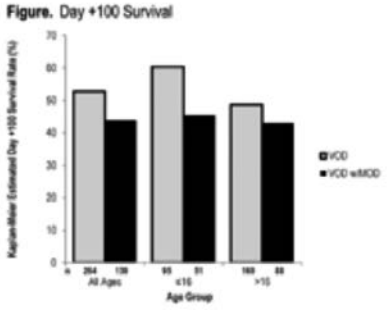

Figure 1.

Summary/Conclusions: In this study, diagnostic criteria requiring onset by day 21 would exclude >26% of pts with VOD/SOS, with more than a third of these being pediatric pts. This highlights the importance of including late-onset VOD/SOS in diagnostic criteria. With DF, 52.8% were estimated to survive to Day +100 (60.4% of pediatric and 48.7% of adult pts). TRAEs for these subgroups were similar to the overall study results. Factors contributing to survival in these pts is a potential area for future exploration.

Support: Jazz Pharmaceuticals.

ALLO-HCT FOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA-12 YEARS OF EXPERIENCE

M. Markiewicz[1,*], M. Dzierzak-Mietla[1], M. Rybicka-Ramos[1], A. Koclega[1], K. Bialas [1], E. Mendek-Czajkowska[2], S. Kyrcz-Krzemien[1]
[1]Hematology and Bone Marrow Transplantation, MEDICAL UNIVERSITY OF SILESIA, Katowice, [2]Hematology Department, Institute of Hematology and Transfusiology, Warsaw, Poland

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal abnormality of hematopoietic stem cell leading to lack of phosphatidylinositol glycoproteins, sensitizing cells to complement-mediated lysis. Despite the efficient symptomatic treatment of hemolytic PNH with eculizumab, allo-HCT is the only curative treatment for the disease, although outcomes presented in the past were controversial.
Aims: The aim of this study was to evaluate the safety and effectiveness of allo-HCT in PNH.
Methods: We report 41 allo-HCTs: 37 from MUD and 4 from MRD performed for PNH in 2004-2016. Median age of recipients was 29(20-62) years and donors 30(19-53), median time from diagnosis to allo-HCT was 16(2-307) months. Median size of PNH clone was 80% granulocytes (0.5%>100%). Indication for allo-HCT was PNH with aplastic/hypoplastic bone marrow (19 pts), MDS (2 pts), overlapping MDS/aplasia (3 pts), severe course of PNH with hemolytic crises and transfusion-dependency without access to eculizumab (17 pts). Additional risk factors were Budd-Chiari syndrome and hepatosplenomegaly (1 pt), history of renal insufficiency requiring hemodialyses (2 pts), chronic hepatitis B (1 pt) and C (1 pt). The preparative regimen consisted of treosulfan 3x14 g/m2 plus fludarabine 5x30mg/m2 (31 pts) or treosulfan 2x10 g/m2 plus cyclophosphamide 4x40mg/kg (10 pts). Standard GVHD prophylaxis consisted of cyclosporine-A, methotrexate and pre-transplant ATG in MUD-HCT. 2 pts instead of cyclosporine-A received mycophenolate mofetil and tacrolimus. Source of cells was bone marrow (13 pts) or peripheral blood (28 pts) with median $6.3x10^8$NC/kg, $5.7x10^6$CD34+cells/kg, $24.7x10^7$CD3+cells/kg. Myeloablation was complete in all pts with median 9(1-20) days of absolute agranulocytosis <0.1 G/l. Median number of transfused RBC and platelets units was 9(0-16) and 8(2-18).
Results: All pts engrafted, median counts of granulocytes 0.5 G/l, platelets 50 G/l and Hb 10 g/dl were achieved on days 17.5(10-33), 16(9-39) and 19.5(11-34). Acute GVHD grade I,II and III was present in 16, 7 and 3 pt, limited and extensive chronic GVHD respectively in 11 and 3 pts. LDH decreased by 73%(5%>91%) in first 30 days indicating disappearance of hemolysis. 100% donor chimerism was achieved in all pts. In 1 patient donor chimerism decreased to 81% what was treated with donor lymphocytes infusion (DLI). 3 patients died, 1 previously hemodialysed pt died on day +102 due to nephrotoxicity complicating adenoviral/CMV hemorrhagic cystitis, two other SAA patients with PNH clone<10% died on days +56 due to severe pulmonary infection and +114 due to aGvHD-III and multi organ failure. Complications in survivors were FUO (10 pts), CMV reactivation (13), VOD (1), neurotoxicity (1), venal thrombosis (1), hemorrhagic cystitis (4) and mucositis (8). 38 pts (92.7%) are alive 4.2 (0.4-12) years post-transplant and are doing well without treatment. Complete disappearance of PNH clone was confirmed by flow cytometry in all surviving pts.
Summary/Conclusions: We conclude that allo-HCT with treosulfan-based conditioning is effective and well tolerated curative therapy for PNH.

P742

A COMPARISON OF CLINICAL OUTCOMES BETWEEN MATCHED SIBLING DONOR (MSD) AND UNRELATED DONOR (URD) STEM CELL TRANSPLANTATION IN ADULT PATIENTS WITH SEVERE APLASTIC ANEMIA

S.H. Shin[1,*], S.S. Park[2], Y.W. Jeon[2], J.H. Yoon[2], S.A. Yahng[3], S.E. Lee[2], B.S. Cho[2], K.S. Eom[2], Y.J. Kim[2], S. Lee[2], C.K. Min[2], H.J. Kim[2], S.G. Cho[2], D.W. Kim[2], W.S. Min[2], J.W. Lee[2]
[1]Hematology, Yeouido St. Mary's Hospital, College of Medicine, The Catholic University of Korea, [2]Hematology, Catholic Blood and Marrow Transplantation Center, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, [3]Hematology, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Allogeneic stem cell transplantation (SCT) using HLA-matched unrelated donor (URD) has been usually regarded as a subsequent option in patients with severe aplastic anemia (SAA), who have failed to immunosuppressive treatment (IST). However, recent improved outcomes of URD SCT lead to its extended role for treating those lacking HLA-matched sibling donor (MSD).
Aims: Through this study, we intended to verify the possibility of URD SCT as a front-line treatment for SAA patients.
Methods: We compared outcomes of consecutive SAA patients who received SCT from 8/8 well-matched URD (WM-URD; n=61) and partially (6/8 or 7/8) matched URD (PM-URD; n=33) with 8/8 matched MSD (n=126) at our institution between Mar 2002 and Dec 2016. Patients receiving MSD and URD SCT were conditioned with fludarabine (180mg/m^2) / cyclophosphamide (100mg/kg IV) plus rabbit ATG (10mg/kg IV), and total body irradiation (fractionated 800cGy)/ cyclophosphamide (100-120m/kg IV) with/without rabbit ATG (2.5mg/kg IV), respectively.
Results: Median age of the WM-URD and the PM-URD groups were significantly lower compared to that of the MSD group (29 yrs, 31 yrs, and 39 yrs; *P* <0.01), with a high proportion of those experiencing IST failures before SCT (80.3%, 90.9%, and 33.3%; *P*<0.01). Median days to neutrophil engraftment of the MSD group was significantly shorter compared to those of the WM-URD and the PM-URD groups (12 days, 16 days, and 16 days; *P*<0.01). The incidences of acute and chronic GVHD of the WM-URD and PM-URD groups were significantly higher compared to those of the MSD group (42.6% and 63.6% *vs* 9.5%; *P*<0.01, and 44.6% and 33.3% *vs* 8.9%; *P*<0.01, respectively). When we compared the incidence of transplant-related mortality (TRM; 10.7% *vs* 7.4% at 6 yrs; *P*=0.53) and overall survival rate (OS; 89.3% *vs* 92.5% at 6 yrs; *P*=0.52) between the WM-URD and the MSD groups, there were no significant difference. However, trends of higher TRM incidence (18.2% *vs* 7.4% at 6 yrs; *P*=0.05) and lower OS rate (81.8% *vs* 92.5% at 6 yrs; *P*=0.05) were observed between the PM-URD and the MSD groups. There was no primary graft failure in either group. Incidence of secondary graft failure of both WM-URD (0% *vs* 18.3%; *P*<0.01) and PM-URD (0% *vs* 18.3%; *P*=0.02) groups were significantly lower compared that of the MSD group. When we adjusted other clinical and transplant-related factors, which include age and IST failure, using multivariate

analysis, the OS rate of the WM-URD group was not significantly different (HR 1.45, 95% CI; 0.52-4.09; *P*=0.48), whereas that of the PM-URD group was significantly lower (HR 2.85, 95% CI; 1.01-8.02; *P*=0.04), compared to that of the MSD group.
Summary/Conclusions: Our study showed that there was no significant difference in OS rate between the WM-URD and the MSD groups. As high incidence of GVHD remains as a problem in the former group, strategies to reduce it are needed in future protocols.

P743

HAPLOIDENTICAL ALLOGENEIC STEM CELL TRANSPLANT IN SEVERE THALASSEMIA PATIENTS

S. Hongeng[1,*], S. pakakasama[1], U. anurathapan[1], B. Andersson[2]
[1]Pediatrics, Ramathibodi hospital, Mahidol University, Bangkok, Thailand, [2]Stem cell transplantation, MD Anderson Cancer Center, Houston, United States

Background: Thalassemia free survival after allogeneic stem cell transplantation (SCT) is about 80–90% with either matched related or unrelated donors. However, the probability of finding a HLA-compatible donor is less than 50%. We explored the use of a mismatched related ("Haplo-") donor.
Aims: To evaluate the outcome of SCT with Haplo donors in severe thalassemia patients
Methods: All patients received two courses of pre-transplant immunosuppression therapy (PTIS) with fludarabine (Flu) 40mg/m2/d together with dexamethasone (Dxm) 25mg/m2 for 5 d to facilitate engraftment. After two courses of PTIS, a reduced-toxicity conditioning regimen of rabbit anti-thymocyte globulin (ATG) 1.5mg/kg/d on days SCT -12,-11,-10, Flu 35mg/m2 on days SCT -7,-6,-5,-4,-3,-2 and IV Busulfan (Bu) 130mg/m2 on days SCT
-7,-6,-5,-4 was given followed by T-cell replete peripheral blood progenitor cells (PBPC). GVHD prophylaxis consisted of cyclophosphamide (Cy) 50mg/kg on days SCT +3 and +4 (Post-Cy), and on day SCT +5 tacrolimus or sirolimus was started together with a short course of mycophenolate mofetil.
Results: Fifty-one patients underwent haplo-SCT. Their median age was ten years (range, 2 to 28 years). Forty-nine patients engrafted with 100% donor chimerism. Two of five patients with high titers of donor-specific anti-HLA antibodies suffered primary graft failure. Median time to neutrophil engraftment was 14 days (range, 11 to 18 days). Eight patients developed mild to moderate, reversible veno-occlusive disease, while twelve patients developed acute GVHD grade II, that quickly responded to steroid therapy. Only seven patients developed limited chronic GVHD. Projected overall and event-free survival rates at two years are 95% and 94%, respectively. The median follow up time is 18 months (range;10 to 50 months).
Summary/Conclusions: This haplo-SCT protocol may yield excellent outcomes for thalassemia patients, and provide a treatment option for patients lacking a HLA-matched donor.

P744

AUGMENTATION OF FLUDARABINE AND BUSULFAN-BASED MYELOABLATIVE REGIMEN WITH THIOTEPA IMPROVES OUTCOMES WITH NO ADDED TOXICITY IN ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA

V.S. Sheth[1,*], N. Boaz[1], S. Grisariu[1], B. Avni[1], R. Or[1], M. Shapira[1]
[1]Stem cell transplant, HADASSAH, Jerusalem, Israel

Background: Allogeneic stem-cell transplantation (HSCT, allo-SCT) is the most effective way to control leukemia relapse for patients with acute myeloid leukemia (AML). Busulfan and Cyclophosphamide (Bu/Cy),the current standard of care, in allogeneic transplant for acute myeloid leukemia (AML), is limited by increased treatment related mortality. Myeloablative doses of Busulfan (12·8mg/kg) with Fludarabine (160mg/m^2) (Flu-Bu), has reduced toxicity, however with the limitation of increased relapses. We have tried to improve outcome of Flu-Bu regimen by augmentation with Thiotepa (10mg/kg). Here we compared outcomes of 45 such patients (getting augmented regimen, Flu-Bu with the addition of Thiotepa, (group 2), to 44 patients who received Fludarabine, Busulfan myeloablative reduced toxicity regimen (group 1), during the same period.
Aims: The primary objective of the report was to compare the toxicity and incidence of relapse between the two regimens. Secondary objective was to compare overall survival (OS), and disease-free survival (DFS), the non-relapse mortality (NRM), engraftment kinetics, incidence of acute and chronic graft *versus* host disease (GVHD), and comparison between high and low-risk patients amongst the two groups.
Methods: 89 patients with AML were retrospectively analyzed. 44 patients were conditioned with Flu-Bu (group 1) and 45 patients augmented with Thiotepa (Flu-Bu-TT, group 2). The transplant conditioning regimen, (augmented myeloablative) consisted of 30mg/m^2 intravenous Fludarabine for 5 days (total dose 150mg/m^2), for matched related donors or for 6 days (180mg/m^2), for unrelated or mismatched donors, intravenous Busulfan (3.2mg/kg/day for 4 days, total dose 12.8mg/kg), and intravenous Thiotepa 5mg/kg for 2 days (10mg/kg). The conventional myeloablative regime was identical, however without the addition of Thiotepa.
Results: Toxicities were comparable, with mucositis in 7 patients (15%) in group 1 and 8 patients (17%) in group 2, (p=1.0), severe sepsis in 4 (9%) in group 1 and 3 (6%) in group 2, (p=0.7), severe venocclusive disease in 2% of group 1 and 4% of group 2, (p=1.0) and comparable non- relapse mortality (NRM), (p=0.7). 5-year disease free survival (DFS), (median follow up of 5 years), was significantly better in group 2, 38% for group 1, and 62% in group 2, (p=0.02) and 5-year overall survival showed trend towards benefit in group 2 (62% *vs* 42%, p=0.06). 14/30 (46%) patients in group 1 relapsed, as compared to 4/31 patients, (12%, p=0.005) in group 2, considering NRM as competing risk.

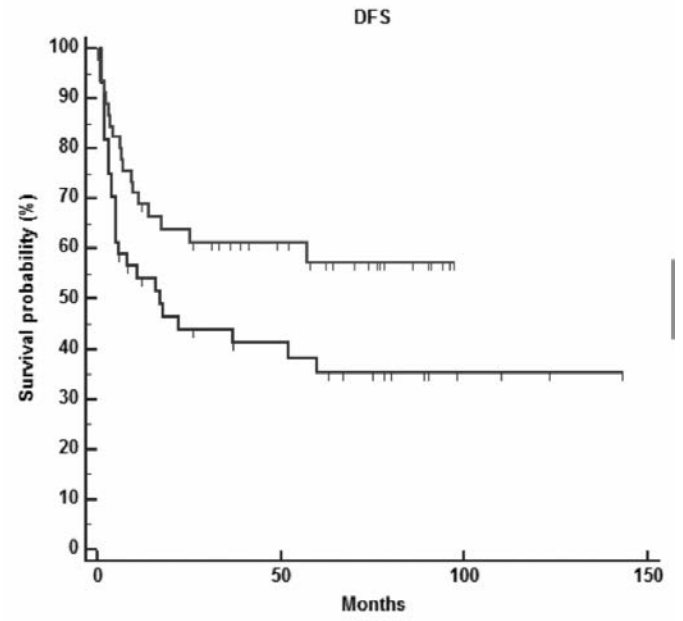

Figure 1.

Summary/Conclusions: In conclusion, the outcome of augmented regimen (DFS and OS) is superior Flu-Bu regime, mainly due to reduction in relapses, with comparable toxicities and could eventually replace Bu/Cy.

P745

PROGNOSTIC TOOLS CAN PROVIDE PERSONALIZED OUTCOMES PREDICTION AFTER ALLOGENEIC HCT IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES

C. Cho[1,*], S. Devlin[2], P. Hilden[2], M. Maloy[1], M. Horowitz[3], J.D. Rizzo[3], B. Logan[3], P. Barba[4], R. O'Reilly[5], S. Giralt[1], M.-A. Perales[1]
[1]Adult Bone Marrow Transplant Service, Department of Medicine, [2]Department of Biostatistics and Epidemiology, Memorial Sloan Kettering Cancer Center, New York, NY, [3]Medical College of Wisconsin and Center for International Blood and Marrow Transplant Research, Milwaukee, WI, United States, [4]Department of Hematology, Hospital Vall d'Hebrón, Universitate Autònoma de Barcelona, Barcelona, Spain, [5]Bone Marrow Transplant Service, Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY, United States

Background: Current prognostic indices for allogeneic HCT (alloHCT) outcomes often focus on a limited set of factors, be they patient characteristics, disease features, or transplant approaches. We sought to evaluate two comprehensive prognostic models in a large sample of patients undergoing alloHCT with CD34 selection (CD34 alloHCT).
Aims: To evaluate two comprehensive prognostic models: The first combining the HCT-Comorbidity Index (HCT-CI) and Disease Risk Index (DRI); the second applying the Center for International Blood and Marrow Transplant Research (CIBMTR) One Year Survival Outcomes Calculator, which uses large-scale multicenter data reported to the CIBMTR to provide patient-specific predictions on survival 1 year after first alloHCT.
Methods: This retrospective analysis included adult recipients of first alloHCT with CD34+ selected PBSCs from 7/8 or 8/8 donors for AML, ALL, or MDS at a single center between 1/2000 and 12/2015. The Kaplan-Meier (KM) method estimated OS and RFS. The cumulative incidence method for competing risks estimated relapse and nonrelapse mortality. We evaluated univariate association between variables of interest and OS/RFS using the log-rank test. Cox regression models assessed the adjusted effect of covariates on OS/RFS. We then determined predicted 1 year OS for each patient using the CIBMTR Calculator. Patients were divided into groups based on predicted OS probability,

in intervals of 5% +/- 2% (*e.g.* 65 +/-2% probability of survival at 1 year). Corresponding observed 1 year OS was then estimated for each group by the KM method. A kernel smoother was used to visually display the average of observed 1 year survival estimates over the continuous range of predicted OS.
Results: 506 patients with AML (n=290), ALL (n=72), or MDS (n=144) were included. Of these, 470 patients (AML=263, MDS=141, ALL=66) had full data available for the CIBMTR Calculator. On univariate and multivariate analyses, DRI, HCT-CI, and age correlated with significant differences in OS/RFS, while donor HLA match correlated with a significant difference in OS. Stratifying patients based on a composite of DRI (low/intermediate *vs* high/very high) and HCT-CI (0-2 *vs* 3+) revealed significant differences in OS/RFS between the 4 groups (Fig. 1). Compared with a reference group of patients with both low/intermediate DRI and low HCT-CI, those with high DRI and low HCT-CI were at greater risk of death (HR 2.30; 95% CI 1.39-3.81) and relapse or death (HR 2.50; 95% CI 1.55-4.05), more so than patients with a higher HCT-CI but still low/intermediate DRI (HR death 1.80; 95% CI 1.34-2.43; HR relapse/death 1.68; 95% CI 1.26-2.24). When comparing predicted and observed survival, KM estimates of 1 year OS fell within range of that predicted by the CIBMTR Calculator in almost all groups (Fig. 1). In one group, patients had lower observed 1 year OS than predicted (76%, 95% CI 62-93%, *vs* 85 +/- 2%, p=NS). In this group, 29/30 patients (97%) had intermediate or high DRI; 59% had poor prognostic AML/ALL by NCCN criteria (n=12, 44%) or other adverse features such as minimal residual disease pre-HCT (n=4, 15%).

Fig. 1: Survival after CD34 allo HCT by two prognostic models

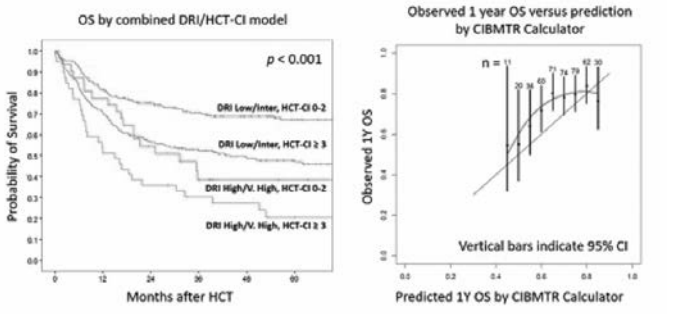

Figure 1.

Summary/Conclusions: Based on a large cohort of patients who underwent CD34 alloHCT for acute leukemia or MDS, we demonstrate that DRI is a major determinant of outcome. The CIBMTR Survival Outcomes Calculator predicts 1 year prognosis with relative precision, though some disease-risk features not reflected in the Calculator may affect outcomes in patients with otherwise good prognosis. Taken together, these prognostic models can assist in predicting outcomes and identifying patients most likely to benefit from CD34 alloHCT. Furthermore, applying the CIBMTR calculator analysis in individual centers may help identify patients with worse outcomes than predicted and guide patient and/or HCT selection.

THROMBOTIC MICROANGIOPATHY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: IS THERE A PROTECTIVE ROLE FOR URSODEOXYCHOLIC ACID?

R. Parody[1,2,*], O. Lopez- Godino[3], F. J. Marquez-Malaver[4], I. García-Cadenas[5], C. Martinez[6], J.L. Piñana[7], L. Lopez-Corral[8], A. Esquirol[9], R. Martino[9], F. Fernandez-Avilés[6], M. Rovira[10], C. Solano[11], D. Caballero[8], J.A. Perez-Simón[4]
[1]Clinical Hematology, H.Universitario Virgen del Rocío, Seville, [2]Clinical Hematology, ICO-Duran i Reynals, Barcelona, [3]Clinical Hematology, H.Universitario de Salamanca, Salamanca, [4]Hematology, H.Universitario Virgen del Rocío, Seville, [5]Hematology, H Santa Creu i Sant Pau, [6]Hematology, H.Clinic, Barcelona, [7]Hematology, H.Clinico, Valencia, [8]Hematology, H.Universitario de Salamanca, Salamanca, [9]Hematology, H.Santa Creu i Sant Pau, [10]Hematology, Hospital Clinic, Barcelona, [11]Hematology, H.Clínico, Valencia, Spain

Background: Thrombotic microangiopathy (TMA) after allogeneic stem cell transplantation (alloSCT) may be a severe complication associated with high mortality. Since there is no standard treatment it would be helpful to have efficacious prophylactic measures. Some data support the beneficial effect of ursodeoxycholic acid (UDA) to prevent endothelial-cell damage.
Aims: We retrospectively analysed a total of 671 patients undergoing to reduced intensity conditioning (RIC) alloSCT, comparing the occurrence of overall TMA according with the use or not of UDA.
Methods: Both uni and multivariate analysis were performed including patient and transplant-related variables at the moment of transplant to analyse the risk of developing TMA.
Results: Cumulative incidence for overall TMA was 4.8 (3.4-6.6) at 1 month, 10.1 (7.9-12.5) at 100 days, and 12.7 (10.3-15.4) at 180 days (figure 1). On univariate analysis, TMA was more frequent in lymphoid malignancies, Fludarabine-melphalan based conditioning, unrelated donor, mismatched donor, prophylaxis with sirolimus-tacrolimus (SRL/TKR), prior transplant and non-UDA patients. The probability of overall TMA at 180 days in UDA patients was 9.6% (95% CI: 5.9-14.3), *versus* 14.7% (95% CI: 11.7-18.1) in non-UDA patients. On multivariate analysis the risk factors which remained statistically significant were unrelated donor and the use of SRL/TKR, whereas the use of UDA significantly decreased the risk of TMA (HR:0.4, 95% CI:0.2-0.8, p:0.01). Moreover, in the subgroup of SRL/TKR, 100 days-cumulative incidence of TMA was 11.8% (95% CI: 6.9-18.1) *versus* 25.6% (95% CI: 17.9-33.9) depending on the use or not of UDA, respectively (p: 0.005), whereas in the subgroup of CNI/MTX 100d-Cumulative incidence of TMA was 3.4%(95% CI: 0.6-10.6) *vs* 12.1(95% CI:7.1-18.6) with and without UDA, respectively (p:0.05).
Summary/Conclusions: In conclusion the use of UDA decreases the risk of TMA after alloSCT regardless of type of immunoprophylaxis.

P747

FACTORS PREDICTING GRAFT *VERSUS* HOST DISEASE-FREE, RELAPSE-FREE SURVIVAL AFTER ALLOGENEIC TRANSPLANTATION. COMPARISON ATTENDING TO TWO DIFFERENT DEFINITIONS AND BENEFICT OF HAPLOIDENTICAL DONOR

O. Lopez Godino[1], E. Pérez López[1,*], S. Alonso Álvarez[1], Ó. Ferré[1], F. López Cadenas[1], N. Arratibel[1], L. Vázquez[1], M.D. Caballero[1], L. López Corral[1]
[1]Hematology department, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Disease free survival is the most common used endpoint for clinical research on allogeneic stem cell transplantation (HSCT), but it doesn't include morbidity endpoints or those which affect their quality of life as graft *versus* host disease (GVHD). Recently, Blood and Marrow Transplant Clinical Trials Network has proposed a composite endpoint: GVHD-free, relapse-free survival (GRFS) for HSCT outcomes. This endpoint includes as event: III-IV acute GVHD (aGVHD), relapse, death or chronic GVHD (cGVHD) requiring systemic treatment. In 2016 EMBT annual meeting a redefinition of this endpoint was proposed changing cGVHD event from those patients with cGVHD requiring systemic treatment (the original one) to those with just severe cGVHD (the redefined one).

• Median day (range)	24 (4-362)	30 (4-252)	22 (4-196)	28 (18-362)	0.001
• III-IV aGVHD	95 (16%)	55 (14%)	37 (20%)	3 (9%)	0.09
cGVHD (*)	318 (61%)	222 (66%)	90 (57%)	6 (20%)	<0.001
• Median day (range)	217 (47-1477)	213 (47-1477)	228 (70-1304)	366 (152-604)	0.1
• Moderate or severe cGHVD	225 (43%)	155 (47%)	68 (43%)	2 (6%)	0.001
(*) from evaluated patients alive at day +100					

Aims: We had generated two composite endpoints: in both III-IV aGVHD, relapse or death were considerated events but we defined GRFS1 as the one with cGVHD event including those who required systemic treatment (as the original one) and in GRFS2 just those with severe cGVHD (the EBMT redefined one) and we had compared both.
Methods: We retrospectively analysed 616 patients transplanted (1995-2016) excluding non-malignant diseases, second allo-SCT and those <16 years old age.

Results: Characteristics of patients are shown in **table 1**. With a median follow up for patients alive of 39 months (3-221), the median estimated survival in months and the % at +1 year and +2 years was: 114 months, 70% and 62% overall survival (OS); 23 months, 57% and 49% event free survival (EFS); 6 months, 35% and 26% GRFS1; 11 months, 46% and 38% GRFS2. 147 (24%) and 218 (35%) hadn't any event in GRFS1 and in GRFS2 respectively. In GRFS1, event's incidence was: 90 (15%) for III-IV aGVHD, 170 (27%) for cGVHD, 152 (25%) for relapse and 57 (9%) for death; In GRFS2 was 90 (15%), 65 (11%), 174 (28%) and 65 (11%) respectively. Considering those patients with cGVHD as event in GRFS1, 105 of them hadn't the event as cGVHD at the same time in GRFS2 (since they had cGVHD requiring systemic treatment but not severe cGVHD). For these patients, the alternative event in GRFS2 was: 72 without any event, 22 relapsed and 11 died. In the multivariate analysis, factors associated with better outcomes were:for GRFS1 diagnosis (p=0,04; benefit in NHL/HL/CLL p=0.02, HR 0.71; CI95% 0.53-0.95), >4 prior lines (p=0.03, HR 1.5, CI95% 1.04-2.04,), early EBMT stage (p<0,001 with early as reference; intermediate p=0,002, HR 1.5, CI95% 1.2-1.9; advance p<0,001, 2.0, 1.5-2.6), *in vivo* T-cell depletion (p=0.02, 0.6, 0.39-0.92) and haploidentical donor (p=0.04 with HLA identical as reference, no significance 1 or 2 mismatch [p=0.18], haploidentical p=0.02, 0.43, 0.25-0.74). Only early EBMT disease stage maintained significance in GRFS2 (p<0,001 with early as reference; intermediate p=0,005, 1.5, 1.1-1.9; advance p<0,001, 1.9, 1.4-2.6).

Summary/Conclusions: In our study the percentage of the GRFS endpoint was similar to previously reported. Comparing both proposed definitions, the GRFS2 endpoint define a higher population of patients without any event; so that it is possible that t morbidity is misdiagnosed. The EBMT disease score was the factor with more impact in both; it is interesting to point that although the group is smaller, haploidentical donor is associated with better GRFS1.

P748

EFFICACY AND SAFETY OF DEFIBROTIDE IN THE TREATMENT OF HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION: FINAL SUBGROUP RESULTS

P. Richardson[1,*], A. Smith[2], B. Triplett[3], N. Kernan[4], S. Grupp[5], J. Antin[6], L. Lehmann[7], S. Giralt[8], W. Liang[9], R. Hume[9], W. Tappe[9], R. Soiffer[7]

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is a potentially life-threatening complication of conditioning regimens for hematopoietic stem cell transplant (HSCT) and may also occur following chemotherapy without HSCT. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Diagnosis has traditionally been based on the Baltimore criteria or modified Seattle criteria. Defibrotide is approved for treating severe hepatic VOD/SOS post-HSCT in the European Union and for treatment of hepatic VOD/SOS with renal/pulmonary dysfunction post-HSCT in the United States. The defibrotide expanded-access protocol was designed to provide access to defibrotide prior to its approval in the United States and to collect additional data on safety and efficacy in a broader patient population, including those with and without MOD, and following HSCT or chemotherapy without HSCT.

Aims: This is an analysis of defibrotide efficacy and safety in the subgroup of patients developing VOD/SOS following HSCT, using final data from the expanded-access protocol.

Methods: The original expanded-access protocol required VOD/SOS diagnosis by Baltimore criteria or biopsy post-HSCT, with evidence of MOD (renal/pulmonary dysfunction). The study was amended to also include patients without MOD (off-label), with VOD/SOS per modified Seattle criteria, and/or with VOD/SOS following chemotherapy without HSCT (off-label). After patients provided informed consent, defibrotide treatment (25mg/kg/d in 4 divided doses of 6.25mg/kg) was recommended ≥21 days.

Results: This analysis of final data is based on 1000 patients enrolled from 2007–2016 who had confirmed VOD/SOS following HSCT and had received ≥1 dose of defibrotide. Of these patients, 512 (51.2%) had MOD. The median age was 14 years (range 0.10–77.0), with 570 patients (57.0%) aged ≤16 years, (281 [54.9%] of whom had MOD) and 430 patients (43.0%) aged >16 (231 [45.1%] of whom had MOD). Among pediatric patients, 28.2% were aged <1–23 months, 52.5% aged 2–11 years, and 19.3% aged 12–16 years. Primary diseases in ≥10% of the overall HSCT group were acute lymphocytic leukemia (19.8%), acute myelogenous leukemia (26.1%), and neuroblastoma (10.5%). Kaplan-Meier estimated Day+100 survival was 58.9% (95% confidence interval [CI], 55.7%–61.9%) in the overall HSCT group (**Figure**), with rates of 49.5% (95% CI, 45.0%–53.8%) in patients with MOD and 68.9% (95% CI, 64.5%–72.9%) in patients without MOD. In patients aged ≤16 years, Kaplan-Meier estimated Day +100 survival was 67.9% (95% CI, 63.8%–71.6%) and 47.1% (95% CI, 42.3%–51.8%) in patients aged >16 years (**Figure**). In the overall HSCT population, 210 patients (21.0%) had ≥1 treatment-related adverse event (TRAE). TRAEs occurring in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

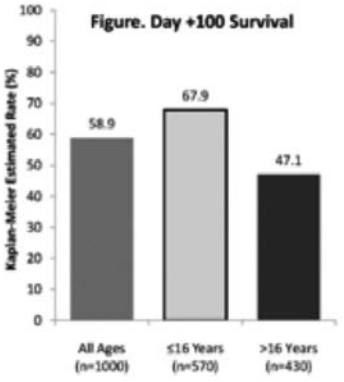

Figure 1.

Summary/Conclusions: This final analysis of the defibrotide expanded-access protocol demonstrates favorable Day +100 survival (58.9%) in patients with confirmed VOD/SOS following HSCT, and 49.5% in those with MOD, a complication typically associated with dismal outcomes. Survival and safety findings, consistent with prior clinical trials, provide supportive evidence for the clinical utility of defibrotide for treatment of VOD/SOS in patients with and without MOD.

GENERATION OF IMMORTAL MURINE HEMATOPOIETIC STEM/PROGENITOR CELL LINES FROM TRANSGENIC MICE

E. Doma[1,*], A. Hölbl[1], V. Sexl[1]
[1]Pharmakologie und Toxikologie, Veterinärmedizinische Universität Wien, Wien, Austria

Background: Research on hematopoietic and leukemic stem cells (LSCs) is currently limited as these cells are infrequent and their immortalization is hardly achieved.
Aims: We aimed to establish a long term *ex-vivo* culture system that allows maintenance and expansion of LSK (lin^-, Sca-1^+, c-Kit^+) cells.
Methods: We adapted a technique described by the L. Carlsson lab and transduced high-purity sorted murine LSKs with *Lhx2*, a LIM-homeobox transcription factor, which has been reported to facilitate *ex vivo* expansion of immature hematopoietic cells.
Results: Lhx2 expressing- hematopoietic progenitor cell (HPC^{LSK}) lines require SCF (stem cell factor) and IL-6 and they can be maintained in a feeder-independent culture for more than 6 months. They preserve LSK markers despite continuous proliferation. HPC^{LSK} cells repopulate lethally irradiated mice and re-feed the entire hematopoietic cell pool. HPC^{LSK} cell lines were established from a range of transgenic mice, underlining the overall applicability of this model. Using this system, we established LSC lines that express BCR/ABL^{p210}, MLL-AF9;$Nras^{G12D}$ or Flt3-ITD; $Nras^{G12D}$. These LSCs home to the bone marrow, differentiate into all lineages and drive myeloid leukemia in mice.
Summary/Conclusions: We created a robust method of expanding hematopoietic stem/progenitor cells. They are immortalized and can be expanded indefinitely. This tool allows analysis of the molecular mechanisms controlling self-renewal in hematopoietic and LSCs as well as drug screening. Our system may represent a breakthrough in (cancer) stem cell biology and assist in the development of new therapeutic avenues to combat LSCs.

INHIBITING BCL2 AND NK CELLS IMPROVES STEM CELL TRANSPLANT OUTCOMES.

J. Davis[1,2,*], Y. Jiao[3,4,5], R. Koldej[1,2], N. Huntington[3,5], D. Ritchie[1,2,6]
[1]The ACRF Translational Research Laboratory, The Royal Melbourne Hospital, [2]Department of Medicine, The University of Melbourne, [3]Department of Molecular Immunology, The Walter and Eliza Hall Institute, Melbourne, Australia, [4]School of Medicine, Tsinghua University, Beijing, China, [5]Department of Medical Biology, The Walter and Eliza Hall Institute, [6]Department of Clinical Oncology and Haematology, The Royal Melbourne Hospital, Melbourne, Australia

Background: Allogeneic haematopoietic stem cell transplantation (alloHSCT) is the most effective means of preventing relapse of blood cancers, in particular AML. The curative potential of alloHSCT is largely due to the immune mediated graft-versus-leukemia (GVL) effect, which in turn is dependent on the stable engraftment of donor immunity. The dual challenge of alloHSCT is therefore to allow sufficient donor engraftment for haematopoietic and immunological reconstitution that drives the GVL effect while limiting the toxicity of conditioning and the onset of graft-versus host disease (GVHD).
Aims: Optimize the use of BCL2 inhibitors to modify recipient NK cell function in models of alloHSCT in order to minimize GVHD severity and onset.
Hypothesis: *Therapeutic targeting of recipient NK cell frequency or function pre-transplant will allow reduced intensity conditioning (RIC) and promote both donor T cell engraftment and GVL whilst reducing the risks of GVHD.*
Methods: We used a MHC-mismatched mouse model of alloHSCT, where donor BM and T cells from BALB/c ($H2K^d$) mice were injected into irradiated C57BL/6 ($H2K^b$) recipients. On day 0, C57BL/6 WT, or $Bcl2^{fl/fl}$ (*Bcl2* deleted in $NKp46^+NK1.1^+$ cells) recipients were irradiated with either a standard dose of 2 x 600 rad, or 2 x 400 rad, before iv injection of 7.5^{e6} BALB/c BM + 1^{e6} T cells. C57BL/6 WT mice were also treated on day -2 and -1 by oral gavage with 100mg/kg ABT-199 or vehicle, before receiving alloHSCT. Mice were monitored for onset of GVHD and tested for early engraftment (day 7-14 post-transplant), and late engraftment (up to day 50).
Results: We utilized genetic and pharmacological models of BCL2 deficiency to establish the role of recipient NK cells as regulators of donor T cell engraftment and GVHD. Conditional deletion of *Bcl2* in NK cells results in a 90% loss of NK cells *in vivo*. $Bcl2^{fl/fl}$ alloHSCT recipients showed robust donor engraftment, but absence of the pro-inflammatory cytokine storm and substantially less GVHD as determined by clinical scores and gut histology, with RIC compared to WT recipients. Pharmacological inhibition of BCL2 in WT recipients recapitulated the transplant findings in $Bcl2^{fl/fl}$ recipients. We found that BCL2 inhibition by Venetoclax (ABT-199), a BCL2 antagonist approved in the treatment of AML, resulted in NK cell apoptosis in human cells. We extended our observations in $Bcl2^{fl/fl}$ recipients to show that pharmacological inhibition of BCL2 in WT mice with just two doses of ABT-199 resulted in rapid depletion of NK cells. Our preliminary data indicates that alloHSCT WT recipient mice pre-treated with ABT-199 develop full donor engraftment even in the setting of significant RIC, with minimal GVHD.
Summary/Conclusions: Recipient NK cell inhibition may therefore represent a means by which to deliver alloHSCT more safely by reducing conditioning intensity and GVHD.

MESENCHYMAL STROMAL CELL IRRADIATION INTERFERES WITH THE ADIPOGENIC/OSTEOGENIC DIFFERENTIATION BALANCE IMPROVING THEIR HEMATOPOIETIC-SUPPORTING ABILITY

S. Preciado Pérez[1,*], S. Muntion[1], A. Rico[1], R. Ortega[1], I. Misiewicz-Krzeminska[1], L.A. Perez Romasanta[1], J. Borrajo[1], T. Ramos[1], L.A. Corchete[1], C. Rodriguez[1], M. Diez-campelo[1], M. López-Parra[1], A. Redondo[1], L.I. Sanchez Abarca[1], M.C. Del Cañizo[1], F. Sánchez-Guijo[1]
[1]IBSAL-Hospital Universitario de Salamanca, Salamanca, Spain

Background: Mesenchymal stromal cells (MSC) are precursors of adipocytes and osteoblasts in the bone marrow (BM) niche, and key regulators of the hematopoietic process. After HSC transplantation, MSC remain of host-origin. Total body irradiation has been widely used in conditioning regimen and MSC are shown to be radio-resistant. Nevertheless, the functional effects of irradiation on BM-MSC have not been extensively explored.
Aims: The main objective was to evaluate the effects of irradiation on the MSC in their hematopoietic-supporting capacity.
Methods: Ten BM samples were obtained from healthy donors after informed consent. MSC were obtained and characterized following standard procedures until third passage. Then, one aliquot was gamma-irradiated with a single dose of 2,5Gy whereas non-irradiated MSC from the same sample were used as controls. MSC were characterized following ISCT criteria (flow cytometry and *in vitro* differentiation stainings). Apoptosis was evaluated by flow cytometry using annexinV/7AAD staining. Expression microarrays of irradiated and control-MSC were performed using Human Gene 2.0 ST Array platform (Affymetrix). RT-PCR of key genes involved in the hematopoietic supporting capacity as well as in the differentiation of MSC into osteoblasts and adipocytes was performed in both experimental groups. Finally, long term BM cultures (LT-BMC) were performed as functional assays to test the hematopoietic-supporting ability of irradiated and control MSC. For the latter experiments, $CD34^+$ cells were isolated from leukapheresis and seeded on stromal layers from non-irradiated or irradiated MSC. CFU-GM colonies derived from the LT-BMC were scored weekly.
Results: Flow cytometric characterization of irradiated MSC was comparable to that of control MSC. Similarly, there were no differences in the percentage of viable cells between both experimental groups neither at one hour nor at 72h post irradiation, confirming once more the radio-resistance of MSC. In addition, expression arrays did not show any statistically significant differences in genes involved in hematopoiesis maintenance. However, upon comparing the differentiation ability we interestingly observed that irradiated-MSC differentiation was skewed towards osteogenesis whereas adipogenesis was impaired. In this regard, irradiated-MSC had significantly higher SPP1 expression (involved in late osteogenic differentiation) and lower CBPA and PPAR-gamma (both genes involved in adipogenesis) compared to control MSC. After inducing *in vitro* differentiation, there were no differences in ALP and Alizarin Red staining but the number of adipocytes per field at days 7, 14 and 21 was significantly lower in irradiated MSC (p=0,018 p=0,046 and p=0,018). In addition, angiopoietin and SDF-1, key genes implicated in maintenance of hematopoiesis, were significantly overexpressed in irradiated-MSC (p=0,043 and p=0,028, respectively). Finally, in the functional evaluation of the hematopoietic-supporting ability of MSC by LT-BMC, we observed that the number of CFU-GM colonies generated by the culture was significantly higher in the irradiated group after 4 and 5 weeks (p=0.046 and p=0.018, respectively) compared to the non-irradiated group. Furthermore, the number of adipocytes per field was significantly reduced in the LTBMC.
Summary/Conclusions: Irradiation of MSC with 2,5Gy improves their hematopoietic supporting ability and modifies their differentiation capacity, increasing the osteogenesis and decreasing the adipogenesis.

DYSFUNCTION OF BONE MARROW MESENCHYMAL STEM CELLS FROM PATIENTS WITH PROLONGED ISOLATED THROMBOCYTOPENIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION CAN BE IMPROVED BY N-ACETYL-L-CYSTEINE

Y. Song[1,2,*], Y. Kong[1], F.-F. Tang[1], H.-Y. Zhao[1], Y.-H. Chen[1], W. Han[1], C.-H. Yan[1], Y. Wang[1], X.-H. Zhang[1], L.-P. Xu[1], X.-J. Huang[1,2]
[1]Peking University Institute of Hematology, Peking University People's hospital, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Prolonged isolated thrombocytopenia (PT), is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) and defined as the engraftment of all peripheral blood cell lines other than a platelet (PLT) count ≤20×10E+9/L or dependence on PLT transfusions for more than 60 days after allo-HSCT. Several clinical risk factors have been proposed to be associated with PT after allo-HSCT. However, the underlying mechanisms remain to be elucidated. Emerging evidence from mouse studies has suggested that effective hematopoiesis depends on a particular bone marrow (BM) microenvironment in which hematopoietic stem cells reside. MSCs represent a key cellular component of the BM microenvironment, which are potential progenitors for osteoblasts, adipocytes, chondrocytes, and marrow stromal cells. The processes of megakaryocytopoiesis and thrombocytopoiesis result from the interactions between hematopoietic progenitor cells, cytokines, and marrow stromal cells derived from MSCs or MSCs directly. However, the functional role of BM MSCs in the patients with PT has never been reported. Moreover, approaches for improving the dysfunction of BM MSCs in patients with PT are lacking.
Aims: To evaluated the number and function of BM MSCs in patients with PT post-allotransplant. Moreover, to investigate the approach to enhance the number and function of BM MSCs derived from patients with PT and its underling molecular mechanisms in vitro.
Methods: Three cohorts were included: patients with PT (N=25), patients with good graft function (GGF, N=12), defined as persistent successful engraftment after allotransplant, and transplant donors as normal controls (N=10). BM MSCs were cultured as previous reported. All experiments were carried out using BM MSCs derived from passages 2–4. The number and functions of BM MSCs were evaluated by fibroblasts colony-forming unit (CFU-F) assay, cell proliferation assay and senescence-associated β-galactosidase (SAβ-gal) assay. Reactive oxygen species (ROS) levels were evaluated by flow cytometry. Protein expression for p-p38, p38, p-p53, p53 was measured by flow cytometry and western blots. To further investigate the potential effect for repairing the dysfunctional BM MSCs, N-Acetyl-L-cysteine(NAC, a ROS scavenger) and SB203580 (p38 inhibitor) were administrated to the BM MSCs from PT patients. After 2 days *in vitro* culture, the number of SAβ-positive cells was counted, the intracellular levels of ROS and p-p38 were evaluated in BM MSCs by flow cytometry.
Results: Human BM MSCs were demonstrated as spindle shape and typical immunophenotype of MSCs at day 21 of cultivation among subjects with PT, GGF and normal controls. Cultures from all normal BM samples produced confluent layers of adherent cells composed of spindled shaped cells. 2 of the 12 GGF BM and 15 of the 25 PT BM failed to produce any adherent layers within 3 weeks of culture. BM MSCs derived from PT patients expanded more slowly and appeared flattened and larger. Proliferative capacity and CFU-F counts of BM MSCs from PT patients were significantly reduced compared to those of GGF patients and normal controls. Moreover, increased levels of ROS, which was associated with increased number of SAβ-positive cells, were identified in BM MSCs from PT patients. Intracellular p-p38 level was significantly elevated in PT patients compared to those in GGF patients. After NAC treatment in vitro, the proliferative capacity was increased significantly, whereas the number of senescent cells, the intracellular levels of ROS and p-p38 were reduced markedly in BM MSCs from PT patients.
Summary/Conclusions: In summary, the current study demonstrated the number and the function of BM MSCs were abnormal in PT patients following allo-HSCT. Moreover, NAC treatment *in vitro* can partially decreased the ROS level and reversed the senescence phenotype through down-regulation of the p38 MAPK pathway. Our results indicate that the dysfunctional BM MSCs may play an important role in the pathogenesis of PT following allo-HSCT and NAC represents a promising therapeutic approach for repairing the impaired BM MSCs in PT patients post-allotransplant.

INHIBITORS OF APOPTOSIS PROTEINS (IAPS) MODULATE GASTROINTESTINAL GVHD IN MURINE EXPERIMENTAL BMT MODELS

T. Toubai[12,*], C. Rossi[3], K. Oravecz-Wilson[2], C. Liu[4], C. Zajac[2], J. Wu[2], Y. Sun[2], H. Fujiwara[2], H. Tamaki[5], D. Peltier[6], M. Riwes[2], I. Henig[2], S. Brabbs[2], P. Reddy[2]
[1]Department of Hematology and Cell Therapy,, Yamagata University Faculty of Medicine, Yamagata, Japan, [2]Department of Internal Medicine, University of Michigan, Ann Arbor, United States, [3]Department of Pediatric Hematology and Oncology, University Hospital of Heidelberg, Heidelberg, Germany, [4]Department of Pathology and Laboratory Medicine, Rutgers-Robert Wood Johnson Medical School, New Brunswick, United States, [5]Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan, [6]Department of Pediatrics, University of Michigan, Ann Arbor, United States

Background: The two Inhibitors of apoptosis proteins (IAPs), X-chromosome-liked linked IAP (XIAP) and cellular IAP1 (cIAP1), inhibit apoptosis and play an important role in regulating innate and adoptive immunity. However, the role of IAPs in allogeneic immune responses is not known.
Aims: We determined the role of IAPs in GVHD.
Methods: We utilized clinically relevant, well-characterized murine models of allogeneic BMT. To chemically target IAPs, we utilized AT406 (SM-406), a SMAC mimetic that actively antagonizes all IAPs.
Results: We first utilized AT406 which regulates TNFα in vitro. Given the GVHD potentiating effects of TNFα, we hypothesized that AT406 will mitigate GVHD. After we confirmed that AT406 reduced expression of IAPs in T cells or host target tissues, we utilized B6→BALB/c MHC-mismatched BMT model. BALB/c recipients were lethally irradiated and transplanted withsyngeneic or allogeneic T cells along with bone marrow (BM). Both groups received either AT-406 or its diluent. Contrary to our hypothesis, allo-recipients receiving AT-406 showed worse GVHD. To understand the role of IAPs, we next utilized B6 background XIAP and cIAP1 deficient animals. When donor T cells from B6-cIAP$^{-/-}$ or XIAP$^{-/-}$ animals were compared to B6-WT T cells, the allo-recipients (BALB/c) showed similar GVHD. Same results were also observed in another B6→F1 model. Furthermore, *in vitro* studies showed that XIAP$^{-/-}$and cIAP$^{-/-}$ T cells had comparable proliferation and cytokine secretion as WT-T cells. These data suggested that increase in GVHD mortality following treatment with AT-406 is not due to its effects on donor T cells. To further dissect the increased mortality after AT-406 treatment, we hypothesized that the absence of IAPs in hosts may impact on GVHD. To test this, cIAP$^{-/-}$, XIAP$^{-/-}$ and WT-B6 animals were lethally irradiated and transplanted with syngeneic (B6) or allogeneic (BALB/c) T cells. Compared to WT recipients, both XIAP$^{-/-}$ and cIAP$^{-/-}$recipients showed increased mortality ($p<0.001$) and worse gastrointestinal (GI) GVHD. To explore whether IAPs regulate GVHD through their expression exclusively in host hematopoietic cells, we generated [B6→B6Ly5.2], [cIAP$^{-/-}$→B6Ly5.2] and [XIAP$^{-/-}$→B6Ly5.2] chimeras and utilized them as recipients in 2nd allo-BMT in BALB/c->B6 models. Both [cIAP$^{-/-}$→B6Ly5.2] and [XIAP$^{-/-}$→B6Ly5.2] showed equivalent GVHD mortality to [B6→B6Ly5.2] chimeras. Consistently, dendritic cells (DCs) from XIAP$^{-/-}$ and cIAP$^{-/-}$ animals showed similar functions as WT-B6 *in vitro*, suggesting that IAP expression in host hematopoietic cells is not critical. Next, to test the role of IAPs in non-hematopoietic GVHD target tissues, we made the reverse chimeras, [B6Ly5.2→B6], [B6Ly5.2→XIAP$^{-/-}$] and [B6Ly5.2→cIAP1$^{-/-}$], where IAPs are absent only in the non-hematopoietic host cells. The allogeneic [B6Ly5.2→XIAP$^{-/-}$] and [B6Ly5.2→cIAP1$^{-/-}$] animals demonstrated a significantly worse survival compared to WT [B6Ly5.2→B6] recipient ($p<0.01$). To determine the potential mechanisms for exacerbating GVHD, we tested tunel staining, and the expression of anti- and pro-apoptotic genes (Bcl-2, BIM, BAL) and autophagy (LC3) in the CD326^{+} intestinal epithelial cells from KO and WT animals after allo-BMT. The cIAP$^{-/-}$ and -XIAP$^{-/-}$ animals showed increased number of tunel positive cells and significantly reduced expression of anti-apoptotic protein Bcl-2 and LC-3 but equivalent expression of pro-apoptotic proteins. In addition, the expression ratio of BIM or BAX to Bcl-2 in allo-XIAP$^{-/-}$ animals was significantly increased.
Summary/Conclusions: These data suggest that enhanced apoptosis in the target tissues in the absence of IAPs contributes to greater GVHD severity. Thus expression of functional IAPs in host target tissues is crucial for reducing the damage from GVHD.

P754

GRAFT-VERSUS HOST DISEASE (GVHD) DEVELOPMENT AFTER BONE MARROW TRANSPLANTATION IS NOT INFLUENCED BY TH9 CELLS

T. Reisser[1], S. Muche[1], J. Scheurer[1], K.-M. Debatin[1], G. Strauss[1,*]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: Th9 cells are a recently defined subset of T helper cells (Th) characterized by the massive production of IL-9. Th9 cells mediate immune responses against helminth infections, exhibit anti-tumor immunity against solid tumors and mediate allogeneic transplant tolerance but they also contribute to immunopathology in allergy and autoimmunity.
Aims: Currently, the role of Th9 cells for GVHD induction and the graft-versus-tumor effect is largely unknown. Therefore, we first explored, whether Th9 cells are induced during GVHD development in two different MHC-mismatched bone marrow transplantation (BMT) models and secondly analyzed, whether transplantation of in vitro-generated Th9 cells mediates GVHD.
Methods: We transplanted allogeneic BM and spleen cells from B6-SJL mice (CD45.1, H-2b) in B6D2F1 mice (CD45.2, H-2bxd) or in B6.bm12 mice (CD45.2, I-Abm12) differing either in 50% of MHC class I and II molecules or only in one MHC class II molecule and analyzed the induction of Th9 cell during GVHD development. To clarify whether in vitro-generated Th9 cells mediate GVHD, we induced Th9 cells *in vitro* from isolated, naïve CD4^{+} T cells on anti-CD3/28 coated plates by TGF-b, IL-4, anti-IFNg and recombinant TL1A and co-injected the Th9 cells together with allogeneic BM in irradiated recipient mice and subsequently monitored GVHD induction.
Results: In both MHC mismatched models used, the transplantation of allogeneic spleen cells and BM leads to GVHD characterized by a time-dependent strong increase of Th1-specific cytokines TNF-a and IFN-g in the serum of the recipient mice. IL-9, however, was undetectable. Additionally, no IL-9 producing allogeneic T cells were identified in the spleen, liver and lung of GVHD-developing animals until 29 days after transplantation, while TNF-a and IFN-g producing cells were strongly increased indicating that Th9 cells are not induced

during GVHD. After *in vitro* differentiation of Th9 cells from naïve T cells we obtained more than 60% of IL-9 producing cells after 5 days of culture. Th9 cells differ in their cytokine profile (IL-9+, IFN-g-, IL-13-) from Th1 and Th2 cells. Transplantation of in vitro-generated Th9 cells together with allogeneic BM cells did not induce GVHD in the MHC-disparate recipient mice, while the transplantation of unselected T cells or in vitro-generated Th1 cells induced GVHD and mediated death in about 60% of the animals. Although no GVHD development was detected, Th9 cells migrated into lymphoid organs and GVHD target organs such as spleen and lung. Surprisingly, when the cytokine phenotype of the transplanted Th9 cells were analyzed after *ex vivo* isolation from spleen and liver at different time points after transplantation, the cells lost their IL-9 production but produced TNF-a and IFN-g pointing to a plasticity of Th9 cells after adoptive transfer. Systemic increase of TNF-a and IFN-g in the serum of mice receiving Th9 cells, however, was not detected.
Summary/Conclusions: Th9 cells are not induced during GVHD development and the adoptive transfer of in vitro-generated Th9 cells does not induce GVHD. However, the transplanted Th9 cells home to spleen and GVHD target organs and start to produce TNF-a and IFN-g without strong systemic increase in these cytokines. Since TNF-a and IFN-g are cytokines associated with an anti-tumor cytotoxicity and Th9 cells are known to eliminate solid tumors, future experiments will define, whether in vitro-generated Th9 cells can be used as a cellular therapy for anti-tumor responses in BM-transplanted hosts.

IMPROVED HSC ENGRAFTMENT IN A MOUSE MODEL OF HEMATOPOIETIC STEM CELL GENE THERAPY MEDIATED BY MSCS

M. Fernandez-Garcia[1,2,*], M. L. Lamana[1,2], M. Hernando-Rodríguez[1,2], R. Sánchez-Domínguez[1,2], J. Bueren[1,2], R. Yañez[1,2]
[1]Division of Hematopoietic Innovative Therapies, Centro de Investigaciones Energéticas Medioambientales y Tecnológicas/Centro de Investigación Biomédica en Red de Enfermedades Raras (CIEMAT/CIBERER), [2]Advanced Innovative Therapies, Instituto de Investigación Sanitaria Fundación Jiménez Díaz (IIS-FJD, UAM), Madrid, Spain

Background: Co-transplantation of human mesenchymal stromal cells (hMSC) has been reported to reduce the risk of graft failure and improve hematopoietic stem cells (HSC) engraftment in xenogeneic and determined allogeneic transplants. In addition, we have demonstrated that the co-infusion of MSCs with low numbers of purified HSCs significantly improve the short- and long-term hematopoietic reconstitution in an autologous HSCT experimental model with sublethal conditioning (5Gy).
Aims: The aim of this study is to analyze the effect of MSCs on HSC engraftment in a clinically relevant model of hematopoietic gene therapy.
Methods: We have studied the effect of MSCs co-infusion in a mouse model of HSC gene therapy with risk of engraftment failure in Fanconi anemia mice (*Fanca*$^{-/-}$).
Results: In these experiments, the infusion of low numbers of WT LSK cells (1,500 LSK) in *Fanca*$^{-/-}$ mice resulted in 30% graft failure, which was prevented when 6.10^5 Ad-MSCs were co-infused. Furthermore, when 1,500-3,000 *Fanca*$^{-/-}$ LSK cells transduced with a therapeutic lentiviral vector (PGK-*FANCA*-wPRE*) were transplanted, the infusion of similar cell doses resulted in more than 50% of engraftment failure, which decreased to 30% only when more than 10,000 gene-corrected LSK were infused. Once again, Ad-MSCs co-infusion prevented graft failure in after the infusion with the same number of gene-corrected LSK cells.
Summary/Conclusions: Taken together, our results demonstrate the potential of Ad-MSCs to avoid graft failure in a clinically relevant model of hematopoietic gene therapy with risks of engraftment failure.

P756

EFFECT OF POMALIDOMIDE ON T CELL POLARIZATION IS MEDIATED THROUGH EPIGENETIC MODIFCATIONS.

I. Alvarez Laderas[1,*], J.I. Piruat[1], T. Caballero Velázquez[1], M. Ceballos[2], V. Barbado[1], L.I. Sánchez Abarca[1], M. Medrano[1], E. Garcia[1], J.C. Reyes[2], J.A. Pérez Simón[1]
[1]Insituto de Biomedicina de Sevilla, [2]Centro Andaluz de Biología Molecular y Medicina Regenerativa (CABIMER), Seville, Spain

Background: There is conflicting evidence regarding the potential use of IMIDs and particularly pomalidomide after allogeneic stem cell transplantation (allo-HSCT). It has been well described that IMIDs polarize naïve T cells towards a Th1 phenotype increasing IFN-γ cytokine production via the augmentation of T-bet transcription factor. This effect might increase the risk of GvHD after allo-HSCT. Nevertheless, a recent trial has reported a potential benefit on the use of pomalidomide as GVHD treatment.
Aims: In the current study, we have analyzed the effect of pomalidomide in the polarization of CD45RA+ cells and the epigenetic mechanisms that might be involved in this effect.
Methods: Isolated CD45RA+ T cells from healthy donor's Buffy Coats were-stimulated with anti-CD3 plus anti-CD28 in the presence of several cytokines to polarize towards Th1 (IL-12, INF-γand anti-IL4) or Th2 (IL-4, IL-2, anti-IFN-γ and anti-IL-12) for 5 days. Pomalidomide at two different doses (10 and 100 nM) were added into the culture and the effect on T cells polarization was analyzed by flow cytometry after staining with anti-CD25, anti-IFNγ, anti-CD4 and anti-IL2 for Th1 cell polarization and anti-CD25, anti-IL10, anti-CD3 and anti-IL4 for Th2 cell polarization. In addition, the release of cytokines (IL-2, IL-4, IL-6, IL-10, TNF-α and IFN-γ) in cell culture supernants were measured with BD Human Th1/Th2 Cytokine CBA kit (BDBiosciences) and T-bet and GATA-3 expression were analyzed by Western Blot. Chromatin immunoprecipitation (ChIP) assays were performed to assess the trimethylation of H3K4 (associated with gene activation) and the trimethylation of H3K27 (associated with gene repression) in the *TBET* and *GATA-3* gene promoters.
Results: Pomalidomide increased the expression of INF-γ and IL-2 as determined by flow cytometry in Th1 cell culture conditions. By contrast, in the presence of Th2 promoting cytokines, we observed an increase for both IL-10 and IL-4 upon adding pomalidomide to the culture. In addition, the exposure to pomalidomide increased the levels of TNF-α, INF-γ and IL-2 in the Th1 polarizing culture while, under Th2 promoting conditions, an increased concentration of IL-4 and IL-2 in supernatant was observed after exposure to pomalidomide. Furthermore, exposure to pomalidomide led to an increased expression of T-bet as assessed by western-blot in naïve CD45RA+ cells activated with anti-CD3 plus anti-CD28 and supplemented with IL-12, INF-γ and anti-IL4. By contrast, in Th2 polarization conditions, pomalidomide increased GATA-3 expression.We next studied whether or not the effect of pomalidomide in T cell polarization might be mediated by epigenetic mechanisms: in the presence of Th1 promoting conditions there was a significant increase of the activation marker H3K4me3 at the *TBET* promoter and a significant decrease in H3K27me3 upon exposure to the drug while, under Th2 promoting conditions, a significant increase in H3K4me3 at the promoter of *GATA-3* gene was observed among T cells exposed to pomalidomide.
Summary/Conclusions: Pomalidomide favours both Th1 and Th2 cell differentiation of CD45RA+ cells depending on the cytokines present in the medium. Treatment of naïve T cells with pomalidomide induces epigenetic modifications during T cell polarization which might favour the process of differentiation of the naïve T cells.

MESENCHYMAL STEM CELLS (MSCS) ATTENUATE CUTANEOUS SCLERODERMATOUS GRAFT-VERSUS-HOST DISEASE (SCL-GVHD) THROUGH INHIBITION OF IMMUNE CELL INFILTRATION IN A MOUSE MODEL

J.-Y. Lim[1,*], D.-B. Ryu[1], S.-E. Lee[1], G. Park[2,3], C.-K. Min[1,3]
[1]Department of Internal Medicine, [2]Department of Pathology, Seoul St. Mary's Hospital, The Catholic University of Korea, [3]Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Human chronic graft-versus-host disease (CGVHD) shares clinical characteristics with a murine sclerodermatous GVHD (Scl-GVHD) model that is characterized by skin thickening and lung fibrosis.
Aims: This study investigated the therapeutic effect of mesenchymal stem cells on the development of Scl-GVHD according to each target organ.
Methods: A B10.D2 → BALB/c transplant model of Scl-GVHD was used to address the therapeutic effect of mesenchymal stem cells (MSCs) on the development of CGVHD. M210B4 cells were administered after allo-HSCT at a dose of 3 x 10^5 cells/mouse on days 3, 5 and 7.
Results: The clinical and pathological severity of cutaneous Scl-GVHD was significantly attenuated in MSC-treated recipients relative to Scl-GVHD controls. After MSC treatment, skin collagen production was significantly reduced with consistent downregulation of *TGF-β* expression. Effects of MSCs on molecular markers implicated in persistent TGF-β signaling and fibrosis, such as phosphatase and tensin homolog (PTEN), phosphorylated Smad-2/3 and matrix metalloproteinase-1 (MMP-1), were observed in skin tissue. MSCs neither migrate to the skin nor affect the *in vivo* expansion of immune effector cells, but inhibited their infiltration into skin via downregulation of CCR4 and CCR8 expression on $CD4^+$ T cells and CCR1 on $CD11b^+$ monocyte/macrophages. MSCs diminished expression of chemokines such as CCL1, CCL3, CCL8, CCL17, and CCL22 in skin. MSCs were also dependent on stimulated splenocytes to suppress fibroblast proliferation.
Summary/Conclusions: Our findings indicate that MSCs attenuate the cutaneous Scl-GVHD by selectively blocking immune cell migration and downregulating chemokines and chemokine receptors.

P758

C57BL/6 SUBTRAINS SHOW DIFFERENCES IN HEMATOPOIETIC REPOPULATION

A. Morales Hernandez[1,*], A. Martinat[2], S. McKinney-Freeman[2]
[1]Hematology, St Jude Children's Research Hospital, [2]Hematology, St Jude Children's Research Hospital, Memphis, United States
Background: C57BL/6 mice are one of the most studied in-bred mouse strains.

Although C57BL/6N (N) and C57BL/6J (J) mice are derived from the same parental C57BL/6 strain, there are key genotypic and phenotypic differences between these sub-strains. However, more than 58% of studies published involving C57BL/6 mice do not indicate the specific sub-strain employed. J mice have a five-exon deletion in the *Nicotinamide nucleotide transhydrogenase* (*Nnt*) gene that results in a non-functional protein. NNT is involved in the resolution of oxidative stress in the mitochondria. Hematopoietic stem cells (HSCs) can reconstitute the entire hematopoietic system after transplantation into hosts whose hematopoietic compartment has been ablated. This is clinically exploited as HSCs transplantation (HSCT) to treat hematologic diseases and represents the only curative therapy for many disorders. During HSCT, HSC are subject to dramatic increases in both intra and extracellular reactive oxygen species (ROS), which compromises their self-renewal, differentiation, and survival. The absence of a functional *Nnt* gene in J-HSC may curtail their ability to resolve elevated ROS post-transplant.

Aims: As elevated oxidative stress compromises hematopoietic stem and progenitor cell (HSPC) function, here we thoroughly interrogated the frequency and function of HSPCs in J and N bone marrow (BM).

Methods: N and J peripheral blood (PB) and BM (n=9) was interrogated by flow cytometry for the absolute frequencies of all major hematopoietic lineages and HSPC compartments, respectively. 5000 J or N CD45.2 HSPCs (Lin-Sca-1+c-Kit+ cells) were transplanted along with 5000 competitor CD45.1 HSPCs into lethally irradiated mice to test for competitive *in vivo* hematopoietic repopulating activity and ROS levels post-transplant. The lineage potential and repopulating activity of multi-potent progenitors (MPP2: Lin-Sca1+cKit+Flt3-CD48+CD150+, MPP3: Lin-Sca1+cKit+Flt3-CD48+CD150-, MPP4: Lin-Sca1+cKit+Flt3+CD48+CD150-) was also tested by transplanting 2000 MPPs from J or N mice into sub-lethally irradiated mice and examining the PB of recipients every 3-4 days for 34 days post-transplant. Sensitivity of HSPCs to oxidative stress was tested by examining ROS levels and the *in vitro* colony forming unit (CFU) potential of HSPCs isolated from N and J mice treated with pI:pC.

Results: The frequency of the major PB lineages and bone marrow HSPC compartments was identical in J and N mice. However, J-HSPCs displayed compromised short-term (4-12 weeks post-transplant) hematopoietic repopulating activity relative to N-HSPCs that was driven by a delay in lymphoid reconstitution. No differences were found in donor contribution to bone marrow HSPC compartments at 20 weeks post-transplant. However, donor-derived MPPs and CLPs displayed a two-fold increase in ROS levels in recipients of J-HSPCs *versus* N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3 and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineage after transplant. J-MPP3s and J-MPP4s displayed less *in vivo* repopulation activity than N-MPP3s and N-MPP4s. It is known that pI:pC treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in HSPCs isolated from pI:pC treated J mice than N mice with the exception of the myeloid progenitor compartments (CMP, GMP and MEO). J-HSPCs also generated fewer and smaller CFU than N-HSPCs when isolated from pI:pC treated mice. These data indicate that J-HSPCs cannot resolve oxidative stress as efficiently as N-HSPCs, which may be due to lower self-renewal potential after exposure to oxidative stress. Short-term J-lymphoid-biased progenitors (*e.g.* MPPs and CLPs) were especially sensitive to increasing ROS, which very likely drives the short-term loss of *in vivo* repopulating activity.

Summary/Conclusions: Based on these data, we hypothesize that loss of the *Nnt* gene in C57Bl/6J mice sensitizes HSPCs to oxidative stress, which compromises their short-term *in vivo* hematopoietic repopulating activity.

GWAS RESULTS IN RED BLOOD CELL PHENOTYPES AND THEIR RELATIONSHIP WITH THROMBOSIS

N. Vilalta[1], S. Lopez[2], A. Perez-Martinez[2], R. Angel F.[3,*], M. Sabater-LLeal[4], P. Sarda[3], N. Pujol-Moix[5], A. Ziyatdinov[2], J. Remacha[3], J. Fontcuberta[1], J. Nomdedeu[3], A. Hamsten[4], J.C. Souto[1], J.M. Soria[2]

[1]Thrombosis and Hemostasis Unit, Hospital de Sant Pau, [2]Unit of Genomics of Complex Diseases, Institut d'Investigació Biomèdica Sant Pau. (IIB-Sant Pau), [3]Hematology, Hospital de Sant Pau, Barcelona, Spain, [4]Cardiovascular Medicine Unit, Department of Medicine,, Karolinska Institutet, Stockholm, Sweden, [5]Medicine Department, Universitat Autònoma de Barcelona, Barcelona, Spain

Background: Venous thromboembolism (VTE) is a complex and multifactorial disease with a estimated heritability of 60%. Intermediate phenotypes of VTE have been used to identify genetic risk factors. We previously reported a genetic correlation of 5 erythrocyte phenotypes with VTE[1].

Aims: To identify single nucleotide polymorphisms (SNPs) influencing the phenotypic variance of erythrocyte parameters, especially those related to VTE, in Spanish families from the Genetic Analysis of Idiopathic Thrombophilia (GAIT2) Project.

Methods: Genome-wide association analyses (GWAS) with ~10M SNPs were performed for eighteen erythrocyte phenotypes in 935 subjects belonging to 35 extended families with thrombosis of GAIT2. The erythrocyte phenotypes evaluated were: Hemoglobin (Hb), red blood cell count (RBC), hematocrit (Ht), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), red blood cell distribution width (RDW), reticulocyte (RET), low fluorescence reticulocyte (LFR), middle fluorescence reticulocyte (MFR), high fluorescence reticulocyte (HFR), reticulocyte fluorescence index (IRF), haptoglobin (HP), serum iron (Fe), total iron binding capacity (TIBC), saturation index (SI), serum ferritin (FT) and serum transferrin receptor (TFR).

Results: We identified 12 SNPs showing association with the 5 erythrocyte phenotypes previously related to VTE (Table 1). Interestingly, the rs56036145 that showed association with TFR is an intronic variant located in the gene *tissue factor pathway inhibitor 2* (TFPI2), which encodes a protein that inhibits a variety of serine proteases of blood coagulation, such as activated factor VII (FVIIa/TF), FXa, plasmin and plasma kallikrein. These data reinforce our previous report of genetic correlation of TFR with VTE. The most significant SNP-associations were reported.

Table 1. Top SNP-associations with erythrocyte phenotypes related to VTE from GWAS in GAIT2.

Phenotype	ρ_G	SNP	Chr.	Type	Closest gene	P value

		rs6000553	22	Intronic	TMPRSS6	$2{\cdot}10^{-6}$
		rs792839	3	Intronic	COL8A1/MIR548G	$4.8{\cdot}10^{-7}$ / $6.6{\cdot}10^{-7}$
TFR	0.4	rs9297983	8	Intergenic	FAM110B	$1.1{\cdot}10^{-7}$
		rs2519651	7	Intronic	GNGT1	$3.3{\cdot}10^{-7}$
		rs56036145	7	Intronic	TFPI2	$3.4{\cdot}10^{-7}$

G: genetic correlation with VTE; Chr: Chromosome.

Summary/Conclusions: Several genetic variants involved in the variance of erythrocyte phenotype levels were identified by GWAS. Of note, TFR was associated with a SNP in *TFPI2* that might influence the variance of both TFR levels and VTE risk. These data could be useful to investigate genes related to red blood cell parameters and VTE.

ESSENTIAL THROMBOCYTHEMIA (ET) AND POLYCYTHEMIA VERA (PV) PATIENTS SHOW AN INCREASED THROMBUS FORMATION IN A DYNAMIC MODEL OF PLATELET ADHESION

A. Vignoli[1,*], F. Marchesi[1], M. Marchetti[1], S. Gamba[1], C. Giaccherini[1], C. Verzeroli[1], L. Russo[1], S. Tessarolo[1], G. Finazzi[2], P.E. van der Meijden[3], F. Swieringa[3], H. ten Cate[4], J.W. Heemskerk[3], A. Rambaldi[2], A. Falanga[1]

[1]Department of Immunohematology and Transfusion Medicine, [2]Department of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy, [3]Department of Biochemistry, [4]Department of Internal Medicine, CARIM, Maastricht University, Maastricht, Netherlands

Background: ET and PV are characterized by a high incidence of arterial and venous thrombosis. Platelet (PLT) count is not an independent risk factor for thrombosis in these conditions. However, no information is available on patient PLT qualitative properties, *i.e.* the PLT thrombus formation capacity in a dynamic condition.
Aims: We wanted to evaluate, in a group of ET and PV patients, the PLT thrombus formation capacity by an *ex-vivo* dynamic model of PLT adhesion under flow conditions, and to establish the influence of JAK2-V617F/Calreticulin (CalR)/MPL mutations, hematological parameters, and ongoing therapies.
Methods: One hundred-thirty patients, *i.e.* 78 ET (32 M/46 F; median age=61 years, range 28-86) and 52 PV (26 M/26 F; median age=65 years, range 38-87), and 32 healthy controls (16 M/16 F; median age=44 years, range 27-61) were enrolled after informed consent. For the adhesion assay, peripheral venous whole blood was drawn in sodium citrate, recalcified in the presence of heparin, and perfused over a collagen-coated surface for 4 min. at a shear rate of 1,000 s^{-1}. PLTs were then stained with an anti-CD62P (P-selectin)-FITC antibody to evaluate PLT activation, and annexinV-AlexaFluor647 to detect pro-coagulant phosphatidylserine expression. After staining, phase contrast and fluorescence images of adherent PLTs were taken in random fields using an EVOS® microscope. Results are expressed as the mean±SEM of the % of area covered by all PLTs (% coverage), or as the % of adherent PLTs positive for either P-selectin or phosphatidylserine. Main hematological parameters, therapies, and mutational status were recorded.
Results: PLT adhesion was significantly ($p<0.01$) greater in either ET (45.3±1.7%) and PV patients (48.9±1.6%) compared to healthy controls (37.5±1.7%), while no difference was found between ET and PV patients. The analysis according to the mutational status shows that ET PLT adhesion was highest in JAK2-V617F mutation carriers (n=41; coverage: 47.7±2.4%, $p<0.001$ *vs* controls), followed by CalR-positive patients (n=21; coverage: 45.5± 3.2%, $p<0.05$ *vs* controls, p=n.s. *vs* JAK2-V617F), while, PLT adhesion of MPL-positive (n=3; coverage: 32.1±2.1%) or triple negative (n=13; coverage: 42.6±2.5%) ET patients was not statistically different from controls. In PV, no statistically significant difference was observed between subjects with >50% *versus* those with <50% JAK2-V617F allele burden. According to treatment, we observed that ET patients treated with the combination of aspirin+hydroxyurea presented the lowest PLT adhesion, while in PV no significant difference was observed between different therapeutic regimens. PLT count correlated ($p<0.01$) with PLT adhesion only in CalR-positive ET patients. The analysis of adherent PLT surface markers shows no difference in P-selectin expression between whole patients and controls. Differently, phosphatidylserine expression was significantly reduced ($p<0.01$) in both ET and PV compared to healthy subjects.
Summary/Conclusions: ET and PV platelets show an increased PLT thrombus formation potential, particularly in patients carrying the JAK2-V617F mutation. On the basis of these results, it is worth to include a dynamic PLT adhesion assay in risk prediction models to evaluate the predictive value of thrombotic events in ET and PV patients. [*Project funded by "AIRC-IG2013" grant Nr. 14505 of the "Italian Association for Cancer Research" (A.I.R.C.)*].

P761

DOAC ASSOCIATED MAJOR GASTROINTESTINAL BLEEDING: REAL LIFE EXPERIENCE FROM A UNIVERSITY TEACHING HOSPITAL, UK

B. Badugama[1,*], S. Mcdermott[1], A. Mrray[2], A. Barua[2], P. Gupta[2], D. Gallagher[2], D. Sutton[1], D. Chandra[1]
[1]Staffordshire Thrombosis & Anticoagulation Centre, [2]Haematology, Royal Stoke University Hospital, Stoke on Trent, United Kingdom

Background: Direct acting oral anticoagulants (DOAC) use is increasing amongst patients requiring anticoagulation for AF or VTE. The incidence of major gastrointestinal (GI) bleeding in DOAC patients from clinical trials is reported to be similar or lower than those on warfarin. There is paucity of real life data confirming this important safety measure.
Aims: We investigated our database on patients using DOAC over a 3 year period to identify major GI bleeding events during this period. The objective was to ascertain the incidence of major GI bleeding and identify demographic and clinical risk factors in these patients.
Methods: all patients issued, apixaban, dabigatran or rivaroxaban between April 2013 - July 2016 were identified from the hospital pharmacy records. Hospital admission data was investigated to identify patients who were diagnosed of a major GI bleeding during this period. Records of patients with major G.I. Bleeding were then individually studied for demographic and clinical risk factors. Major bleeding was defined as per the ISTH criteria.
Results: 2611 patients were identified to have received DOAC treatment between April 2013- July 2016. Of these 1601 (61%) received; apixaban, 722 (27%) rivaroxaban and 288 (11%) dabigatran.18 patients (0.7%) suffered from a major GI bleeding equating to annual risk of major GI bleeding of 0.23% per patient/ year. This is a much lower incidence than reported data from clinical trials in patients on DOAC. Patients who suffered from a major GI bleeding did so on average 143 days (range 8-576) after starting the DOAC. Of all patients with major GI bleeding, 14 were taking apixaban (0.8% of all pt on apixaban), 3 (0.4% of all pt on rivaroxaban) rivaroxaban and 1 (0.3% of all pt on dabigatran) on dabigatran). The numbers were too small to identify any statistical difference between the 3 different DOAC drugs.
Summary/Conclusions: The risk of major GI bleeding in our cohort of over 2500 patients over 3 years was noted to be significantly lower than trial data. Since this is a retrospective review from patient hospital database there is a risk of reporting bias and under-reporting of bleeding events. A prospective phase IV study to identify bleeding risk in patients on DOAC is required. Majority of patients with major GI bleeding had other risk factors such as concurrent use of anti- platelets, peptic ulcer disease, alcohol abuse, oesophageal varices, diverticular disease, and bowel malignancy which would increase their bleeding risk on any anticoagulation. Further sub group analysis of this cohort and efforts to improve reporting of anticoagulation associated bleeding is underway.

Abstract withdrawn.

P763

INCIDENCE OF VENOUS THROMBOEMBOLISM IN PATIENTS UNDERGOING LOWER LIMB SURGICAL REVASCULARIZATION: IS THROMBOPROPHYLAXIS WARRANTED?

A. Baranwal[1], S. Singh[1], A. Yanamadala[1], P. Smith[1,*], E. Colaiuta[1]
[1]MacNeal Hospital, Berwyn, United States

Background: The incidence of postoperative deep vein thrombosis (DVT) or consequential pulmonary embolism (PE) in patients undergoing lower extremity surgical revascularization procedures is not well studied. The need for routine anticoagulation for DVT/PE prophylaxis after the lower limb surgical revascularization remains controversial.
Aims: The purpose of this study is to retrospectively evaluate the incidence of postoperative DVT/PE in patients undergoing lower limb surgical revascularization.
Methods: Charts for patients undergoing lower limb surgical revascularization, from 01/01/2010 to 12/31/2015, were evaluated for DVT/PE. DVT/PE within three months of the revascularization was considered to be a postoperative DVT/PE. Patients undergoing multiple procedures were counted as different cases if they were on different days. Multiple procedures on a patient on the same day were considered a single case. Patients with hypercoagulable states or previous history of DVT were excluded. Descriptive statistics and t-test was used to analyze incidence of DVT/PE and assess the importance of postoperative thromboprophylaxis.

Table 1.

	DVT/PE within three months from surgery	
Procedure performed	**No**	**Yes**
Balloon angioplasty	15	
Bypass aorta-femoral	18	
Bypass femoral-peroneal	3	
Bypass femoral-femoral	12	1
Bypass femoral-popliteal	252	2
Bypass femoral-tibial	6	
Lower limb embolectomy	3	
Femoral artery exploration	6	
Thrombectomy	39	2
Total	354	5

Results: Between 1/1/2010 to 12/31/2015, 360 patients were found to have undergone lower extremity surgical revascularization. Study population included 200 males and 160 females. Mean patient age was 69.54 years. One patient had a previous history of DVT and was excluded. Overall, of the 359 patients, five (1.4%) were recognized to have a new DVT/PE within 3 months of the surgery. One patient developed DVT in the contralateral limb, and one developed it in the arm. Patients were recognized to have a new DVT/PE, on an average, at 7.6 days after the surgery. A one sided t-test demonstrated that the average

postoperative day for recognition of DVT/PE was significant greater than 3.5 (7.6 *vs* 3.5, t-value=2.17, *p*=0.048). Patients developing DVT/PE did not differ by obesity or age when compared with non-DVT/PE population.
Summary/Conclusions: There have been only a few studies to assess the incidence of DVT/PE in patients undergoing lower limb surgical revascularization. In our study population, 1.4% of patients had evidence of DVT/PE. This constitutes a low risk of venous thromboembolism. The 2012 American College of Chest Physicians (ACCP) guidelines for prevention of venous thromboembolism in nonorthopedic surgical patients (Chest 2012; 141(2)(Suppl):e227s-e277s), recommends the use of pneumatic compression devices (PCDs), over no prophylaxis, to prevent DVT/PE in low risk patients. Since, patients with lower limb surgeries are not a good candidate for PCDs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patient, it might be prudent to start thromboprophylaxis 3.5-4 days after the surgery. Further studies are needed to assess the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.

Background: Renal cell carcinoma (RCC) may increase the risk for venous thromboembolism. However, only a few reports have described the clinical features and risk factors for thromboembolism.
Aims: This study aimed to elucidate the clinical features of thromboembolic events and to identify prognosis in patients who experienced thromboembolism events.
Methods: We retrospectively reviewed medical records of patients who underwent nephrectomy at our institution between February 1998 and August 2015. We evaluated the data including pathologic stage, gender, age, smoking history, underline disease, preoperative laboratory findings and survival outcomes.
Results: A total of 3099 patients were included in the study. Among them, 208 thromboembolic events (6.7%) were identified in pathologic and image studies during median follow-up duration of 40 months. Patients who have increased preoperative platelet levels ((≥400x10^{3}uL), neutrophil lymphocyte ratio (NLR) (≥1.86) and c-reactive protein (CRP) (≥0.12mg/dL) experienced significantly more thromboembolic events than those with lower value according to multivariable analysis (hazard ratio [HR], 2.22 [95% CI, 1.01–4.85], *P*=0.047 for platelet levels; HR, 3.39 [95% CI, 1.67–6.90], *P*=0.001 for NLR;HR, 3.38 [95% CI, 1.67–6.80], *P*=0.001 for CRP). Moreover, patients who experienced thromboembolism showed poor overall survival (OS 195 *vs* 67 months HR 1.95, P=0.007).
Summary/Conclusions: Preoperative inflammation markers including NLR, CRP and platelet cout can be the risk factors for venous thromboembolism in RCC patients who experienced nephrectomy. Thromboembolism also has a significant role on the the prognosis of RCC patients.

P765

GENETIC AND ENVIRONMENTAL RELATIONSHIP BETWEEN VITAMIN B12, FOLATE AND HOMOCYSTEINE AND SUSCEPTIBILITY TO THROMBOSIS IN THE GAIT 2 PROJECT. RESULTS OF A GWAS ANALYSIS

R. Angel F.[1,*], A. Perez-Martinez[2], N. Vilalta[3], S. Lopez[2], M. Sabater-LLeal[4], P. Sarda[1], N. Pujol-Moix[5], A. Ziyatdinov[2], J. Remacha[1], J. Fontcuberta[3], J. Nomdedeu[1], A. Hamsten[4], F. Blanco-Vaca[6], J.C. Souto[3], J.M. Soria[2]
[1]Hematology, Hospital de Sant Pau, [2]Unit of Genomics of Complex Diseases, Institut d'Investigació Biomèdica Sant Pau. (IIB-Sant Pau), [3]Thrombosis and Hemostasis Unit, Hospital de Sant Pau, Barcelona, Spain, [4]Cardiovascular Medicine Unit, Department of Medicine,, Karolinska Institutet, Stockholm, Sweden, [5]Medicine Department, Universitat Autònoma de Barcelona, [6]Biochemistry, Hospital de Sant Pau, Barcelona, Spain

Background: Venous thromboembolism (VTE) is a common disease involving genetic and environmental risk factors. Earlier studies have estimated that the heritability of the risk of VTE is 60% and we have demonstrated that erythrocyte-related phenotypes are good candidates for risk factor of thrombosis (Genetic Analysis of Idiopathic Thrombophilia 2, GAIT 2, Project).
Aims: To replicate the estimates of the heritability, and to evaluate the role of intermediate phenotypes as VTE risk factors.
Methods: Thirty-five Spanish extended families were recruited in the GAIT 2 Project. The sample consisted of a set of 935 individuals. Inclusion criteria were similar to GAIT 1. Levels of serum vitamin B12 (B12), serum folate (SF), red cell folate (RCF) and homocysteine (HCY) were evaluated using commercial automated methods. Heritability (h2) estimates were obtained using the variance component method. The correlations between a given pair of traits were calculated using a multivariate variance component model. By studying these traits in extended families we estimated both the genetic (ρg), and the environmental (ρe) correlations between traits. All of the statistical analyses were performed employing the Sequential Oligogenic Linkage Analysis Routines (SOLAR, version 6.6.2, official). Then a GWAS analysis was carried out.
Results: The h^2 of VTE was 0.67. All parameters showed significantly high h^2, and environmental (especially in the case of HCY) factors were also related to these parameters (table 1). In addition, VTE was correlated with B12 (0.34. p=0.027). Moreover, B12 was related to autoimmunity (0.5. p= 0.03) and RCF with malignancy (-0.58, p=0.05). The GWAS analysis detected numerous signals (table 2). Some of these signals have been reported (B12 and FUT2, SF and Hcy and MTHFR).

Table 1. Values, heritabilities, household effect and significant covariates effects.

TRAIT	Value	h^2	p value (h^2)	c^2	Covariables
B12 (pmol/l)	441±240 (74-4558)	0.47	2.95×10^{-17}	0.11	Age, contraceptio n, smoking
SF (nmol/l)	21±7.6 (6.2-45.4)	0.27	2.3×10^{-6}	0.07	Sex, contraceptio n, smoking
RCF (nmol/l)	1241±481 (435-3554)	0.42	1.85×10^{-13}	0.06	Age, sex, smoking
HCY (µmol/l)	10.4±5.5 (2.7-97.7)	0.26	3.61×10^{-5}	0.41	Age, sex, smoking

Values expressed as Mean±standard deviation, in brackets maximum and minimum values. B12: serum vitamin B12; SF: Serum folate; RCF: Red cell folate; HCY: Homocysteine.

Table 2. Suggestive signals detected by GWAS.

Variable	Chromosome	Gene and rs	P value
B12	19	FUT 2 rs516246	1.7x10-7
	6	GLYATL3 rs3957334	1.4x10-7
SF	1	MTHFR rs1801133	1.3x10-6
	12	TMEM132C rs1683701	1.4x10-6
RCF	9	Intergenic rs 73651941	1.13x10-6
HCY	1	MTHFR rs1801133	2.5X10-10
	9	Intergenic rs77630217	1.2x10-6
	11	ELF5 rs3824896	2.7x10-7

Summary/Conclusions: In the GAIT2 study, genetic and environmental factors were related to B12, SF, RCF and HCY. Moreover, a relationship was observed between B12 and VTE. In the GWAS analysis some signals were previously reported (FUT2 and B12 or MTHFR with SF and HCY). New signals were found that need to be clarified, especially their possible relationship with susceptibility to thrombosis.

P766

CELLULAR ORIGIN OF CIRCULATING MICROPARTICLES (MP) ACCORDING TO SOMATIC MUTATIONS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPN)

C.J. Tartari[1,*], M. Marchetti[1], R. Lacroix[2], L. Russo[1], S. Gamba[1], A. Vignoli[1], G. Finazzi[3], A. Rambaldi[3], A. Falanga[1]
[1]Department of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, [2]Department of Hematology and Vascular Biology, Hospital La Conception, Marseille, France, [3]Department of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy

Background: Essential thrombocythemia (ET) and polycythemia vera (PV) are MPN characterized by a high rate of thrombotic complications. We previously demonstrated increased plasma levels of procoagulant MP in ET (Marchetti *et al.* A.J.H. 2013).
Aims: Aim of this study was to extend the analysis of MP to PV patients and to characterize the cellular origin of plasma MP in both ET and PV patients. The influence of somatic mutations [i.e. JAK2V617F, calreticulin (CalR), thrombopoietin receptor (MPL)] and concomitant cytoreductive or antiplatelet therapies was also evaluated.
Methods: Thirty-seven ET (19 JAK2V617F, 9 CalR and 2 MPL mutation carriers), 35 PV patients (all JAK2V617F carriers) and 36 healthy control subjects were included into the study. Flow cytometry was performed to characterize MP phenotype in platelet free plasma samples. To define MP cellular origin, anti-CD31 (endothelial cell marker), anti-CD41 (platelet marker), anti-CD11b (leukocyte marker), and anti-CD235 (erythrocyte marker) monoclonal antibodies were used. Annexin V (AnnV) staining was used to evaluate the expression of procoagulant phosphatidylserine on MP.
Results: ET and PV patients displayed significantly higher MP levels compared to controls (p<0.05). The majority of circulating MP (90%) were AnnV positive, indicating the expression of phosphatidylserine on their surface. In healthy con-

trols, 71% of MP was positive for platelet (P-MP), 24% for erythrocyte (E-MP), 4% for endothelial cell (EC-MP) and 1% for leukocyte (L-MP) specific markers. In ET and PV patients, the percentage of P-MP was significantly higher (80%; p<0.05), while E-MP level was significantly lower (15%; p<0.05) than controls. L-MP and EC-MP values were comparable between patients and controls. The absolute counts of P-MP and L-MP were higher in both ET and PV *versus* controls. Overall, no significant correlations were found between the levels of MP derived from platelet, leukocytes or erythrocytes and the corresponding cell counts. The analysis according to patient mutations, revealed significantly higher levels (p<0.05) of both P-MP and E-MP concentration in patients carrying JAK2V617F mutation as compared to JAK2V617F negative patients. In addition, ET patients positive for CalR mutation displayed lower levels (p<0.05) of P-MP compared to JAK2V617F carriers. No influence of concomitant therapies on MP levels or composition was observed.
Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to the presence of different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

P767

ARE WE TESTING APPROPRIATELY FOR THE LUPUS ANTICOAGULANT?

J. Sharif[1,*], C. Humphrey[1], I. Earnshaw[1], J. Thachil[1]
[1]Haematology, Central Manchester University Hospitals, Manchester, United Kingdom

Background: The diagnosis of antiphospholipid syndrome (APS) requires the presence of thrombosis or defined pregnancy morbidity in addition to the presence of antiphospholipid antibodies on at least 2 occasions. Patients should be tested for antiphospholipid antibodies if they fulfil the required clinical criteria. Lupus anticoagulant may also be tested for when investigating a prolonged activated partial thromboplastin time which does not correct on mixing studies.
Aims: The aim of our study was to examine retrospectively the frequency of lupus anticoagulant (LA) testing in our institution, which we suspected to be high, and the incidence of positive results leading to a diagnosis of APS.
Methods: A total of 914 requests for LA were received over a 5 month period between 1st of May and 30th September 2014. We examined which departments were requesting the tests and the clinical indications for testing.
Results: Over 90% (829) of LA tests were negative. Nine percent (85) of tests demonstrated a positive LA. 33 patient had experienced arterial (11) or venous (22) thrombosis. There were 3 patients who fulfilled the clinical criteria for pregnancy morbidity in APS. A total of 6 patients experienced miscarriage before 10 weeks gestation; however none of these patients had the defined 3 miscarriages. There was one preterm delivery at 25 weeks due to pre-eclampsia. A further 3 patients had a still birth, one of which had an identifiable cause. In total, of the 85 positive results, 12 patients had a confirmed diagnosis of APS; a further 25 patients had the clinical manifestations fitting the clinical criteria for APS. Fourty eight patients had a positive LA but did not fit the clinical criteria for a diagnosis of APS. The clinical specialities requesting the majority of tests were obstetrics and gynaecology (231), rheumatology (179) and clinical haematology (118). Of these, clinical haematology had the highest yield of positive results (16%) compared to 3% in obstetrics and gynaecology.
Summary/Conclusions: Our results highlight a high frequency of LA testing in our institution with a low yield of positive results (9%), resulting in a total of 1% of patients being diagnosed with APS. Our results demonstrate that the majority of tests for LA are not of clinical significance and often requested in patients not fitting the clinical criteria for APS. Further education for all practitioners would help to ensure only appropriate patients are tested. Indeed if a patient fits the clinical criteria for APS they should be tested for all antiphospholipid antibodies namely anti-cardiolipin and anti-β2-glycoprotein I as well as the lupus anticoagulant.

P768

RESULTS OF USING BRIDGING THERAPY WITH SODIUM BEMIPARIN AT THERAPEUTIC-DOSE

M.A. García Ruiz[1,*], E. Morente Constantin[1], P. Romero Garcia[2], M. Gómez Morales[1], M. Jurado Chacón[1]
[1]Servicio de Hematología y Hemoterapia, Complejo Hospitalario Universitario de Granada, Granada, [2]Unidad de Cuidados Intensivos, Complejo Asistencial de Soria, Soria, Spain

Background: Bridging therapy consists of the administration of a fast-acting anticoagulant such as the low-molecular-weight heparin (LMWH) during the period of cessation of oral anticoagulant therapy. The decision to continue with anticoagulant therapy or to discontinue the treatment with the establishment of the Bridging therapy have been carried out carefully and on an individual basis. While taking this decision, we have taken into account three factors: the urgency of surgery or invasive process, the risk of bleeding and thrombotic risk for the patient. In recent decades, there have been multiple studies supporting the LMWH treatment, at least as safe and effective and more cost-effective than unfractionated heparin (UFH) in the prophylaxis and treatment of venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE). Therefore, the LMWH is considered as the drugs of choice in the prevention of venous thromboembolism.
There are several types of commercialized LMWH, with different pharmacological properties, such as molecular weight, anti-Xa/IIa ratio and average life. The sodium bemiparin is the LMWH with greater anti-Xa/IIa ratio, which implies a lower risk of bleeding. In addition, it has shown a low incidence of VTE and bleeding in actual clinical practice.
Aims: There are few published data from bridging therapy at therapeutic doses in patients treated with oral anticoagulants (AVK) and perioperative management. It is intended to assess the efficacy (recurrence of thrombosis) and safe use of sodium bemiparin at anticoagulant doses on the bridging therapy and possible thrombotic and / or hemorrhagic complications (major and minor bleeding) resulting from this use.
Methods: We have analyzed 975 bridging therapies at full dose in our clinic in the last year. They were made to a total of 650 patients (315 men and 335 women) with CHADSVASC >2, aged between 15 and 92, with an average age of 69 years old. The reasons of anticoagulation in our patients were atrial fibrillation, mechanical prostheses, DVT, pulmonary embolism and recurrent thrombosis in patients with thrombophilia. In 70% of the cases, there were comorbidities, such as heart failure, chronic obstructive pulmonary disease, anemia, kidney failure, liver disease and long-term aftereffects of stroke. The bridging therapy has consisted on suspending AVK 4 (acenocumarol) to 6 days (warfarin) before the procedure, and replacing it by sodium bemiparin at full doses <50 kgr: 5,000 IU/24h, 50 to 70 kgr: 7,500 IU/24 h, 70-100 kgr: 10,000 IU/24 h and >100 kgr: 12.500 IU/24 h, and administration of a prophylactic dose of 3,500 IU, 12 hours before the procedure, and another dose 6-12 hours after the procedure, depending on the risk of bleeding of the intervention and the thrombotic risk of the patient's disease. The bridging therapy has been performed in 225 cases of major surgery (orthopedic surgery, ophthalmological procedures, valvular replacements etc), 340 cases of minor surgery (removal of nevus, complex dental extractions, dental implants), 295 cases of invasive procedures (colonoscopies, endoscopies..), 50 cases of bleeding caused by AVK (epistaxis, petechiae and bruises, hemoptysis, menorrhagia and gastrointestinal bleeding), 30 cases of hospitalization with INR decompensation with various causes (infectious endocarditis, pneumonia, uncompensated heart failure...) and 35 cases for thrombophilia study.
Results: As complications of using bemiparin sodium, there have been: 40 cases of hematomas at the needle puncture sites. There was neither cases of major bleeding nor cases of thrombosis.

Table 1.

	Episodes of use of the different doses of bemiparin
Bemiparin 5000 UI/24h	95
Bemiparin 7.500 UI/24h	465
Bemiparin 10.000 UI/24h	376
Bemiparin 12500 UI/24h	30

Summary/Conclusions: Sodium bemiparin administered at therapeutic doses (115 IU/kg/24h) in the perioperative period, according to the scheme described above, it is associated with a low incidence of recurrence of VTE and bleeding. The complications presented in our sample have been very few, in patients with associated co-morbidities. In our study, sodium bemiparin has shown to be safe and effective with minimal bleeding complications. Treatment should be administered on an individual basis according to each patient and factors related to surgery. Further studies will confirm our results.

Background: Ibrutinib is a first-in-class, once-daily oral inhibitor of Bruton's tyrosine kinase. Ibrutinib as a single agent is indicated by the EMEA and US FDA for the treatment of adult patients with CLL and allows for treatment without chemotherapy. The phase 3 RESONATE trial in patients with relapsed CLL showed superior efficacy of ibrutinib compared with ofatumumab (Byrd NEJM 2014).
Aims: We report updated safety and efficacy results of the RESONATE trial with up to 4 years of follow-up.
Methods: Eligibility criteria included ≥1 prior therapy, ineligibility for treatment with a purine analog, and ECOG performance status 0-1. Informed consent was obtained from all patients prior to study initiation. Patients received oral ibrutinib (420 mg once daily) until disease progression or unacceptable toxicity or intravenous ofatumumab (300 mg week 1; 2000 mg weekly for 7 weeks and then every 4 weeks for 16 weeks) for up to 24 weeks. At the interim analysis (median follow-up of 9 months), the data monitoring committee declared superiority of ibrutinib *vs* ofatumumab for progression-free survival (PFS) and overall survival (OS), and access to ibrutinib was recommended for all patients in ofatumumab arm who had disease progression. Long-term follow-up of efficacy endpoints are per investigator assessment. Patients randomized to ofatumumab were censored at crossover for OS.
Results: A total of 391 patients were randomized to receive ibrutinib (n=195) or ofatumumab (n=196). The median age was 67 years, with 40% age ≥70 years, and Rai stage III/IV in 57% of patients. At a median follow-up of 44 months (maximum 53 months) for the ibrutinib arm, PFS was significantly longer for ibrutinib *vs* ofatumumab (median NR *vs* 8 months, [HR 0.133; *P*<0.0001]). The 3-year PFS was 59% for ibrutinib *vs* 3% for ofatumumab. A significant PFS benefit was observed across baseline subgroups. In the ibrutinib arm, PFS for the del11q subgroup trended to have the most favorable outcome; however, PFS outcomes were not statistically different for patients with del17p or del11q or patients without these FISH abnormalities. At time of analysis, with the majority of patients randomized to ofatumumab (68%) crossing over to receive ibrutinib therapy, OS was longer for ibrutinib *vs* ofatumumab (median OS NR for either arm). The 3-year OS rate for ibrutinib was 74%. The ORR for ibrutinib was 91% with a CR/CRi rate that increased over time (currently 9%). Baseline cytopenias improved with extended ibrutinib therapy for hemoglobin (85% of patients), platelet (95% of patients), and absolute neutrophil counts (95% of patients). The adverse event (AE) profile of ibrutinib was consistent with previous reports. During a follow-up of up to 4 years, major hemorrhage occurred in 6%, grade ≥3 atrial fibrillation occurred in 6%, and grade ≥3 hypertension occurred in 8% of patients. The incidence of most grade ≥3 AEs decreased from year 1 *vs* year 2-3: neutropenia: 18% *vs* 8%; pneumonia: 11% *vs* 4%; atrial fibrillation: 4% *vs* 2%, respectively. The most frequent reasons for treatment discontinuation were progressive disease (27%) and AEs (12%). At analysis, 90 patients randomized to ibrutinib (46%) continue to receive ibrutinib.
Summary/Conclusions: In this international phase 3 RESONATE study with median follow-up of up to 4 years, long-term treatment with ibrutinib showed a favorable tolerability profile with sustained PFS and OS benefit regardless of high-risk cytogenetics. The results in relapsed del17p and del11q patients compared favorably to those previously reported in phase 2 studies.

S770

THE INITIAL REPORT OF THE BLOODWISE TAP CLARITY STUDY COMBINING IBRUTINIB AND VENETOCLAX IN RELAPSED, REFRACTORY CLL SHOWS ACCEPTABLE SAFETY AND PROMISING EARLY INDICATIONS OF EFFICACY

P. Hillmen[1,*], A. Rawstron[2], T. Munir[3], K. Brock[4], S. Munoz Vincente[4], Y. Jefferson[4], K. Paterson[4], C.P. Fox[5], J. Gribben[6], A. Bloor[7], A. Schuh[8], F. Forconi[9]
[1]Experimental Haematology, University of Leeds, [2]H.M.D.S., St James's Institute of Oncology, [3]Haematology, St. James's Institute of Oncology, Leeds, [4]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, [5]NHS Nottingham University Hospitals, Nottingham, [6]Barts Cancer Institute, London, [7]Christie Hospital NHS Trust, Manchester, [8]Churchill Hospital, Oxford University Hospitals, Oxford, [9]Southampton General Hospital, Southampton, United Kingdom

Background: Ibrutinib (IBR) is an oral BTK inhibitor with high response rates in CLL. Venetoclax (VEN) is a potent, highly selective, orally bioavailable small-molecule BCL2 inhibitor. Both IBR and VEN are approved by both the FDA and EMA as single agents for chronic lymphocytic leukaemia (CLL). IBR leads to a rapid nodal response with re-distribution of CLL into the peripheral blood whereas VEN leads to depletion of CLL cells to levels in some patients where they cannot be detected. Two of the key cellular processes that are abnormal in CLL are proliferation and apoptosis. The combination of IBR with VEN is therefore logical as biologically the two drugs would be expected to be synergistic. The eradication of minimal residual disease (MRD) from blood and bone marrow is associated with improved outcome in any treatment of CLL where it has been reported.
Aims: The CLARITY trial (ISCRTN: 13751862) is a feasibility study to investigate the safety and efficacy of IBR combined with VEN in patients with relapsed/refractory CLL. Here we report for the first time the safety of the combination as well as early signs of potent synergy.
Methods: After 8 weeks of IBR monotherapy (420mg/day), VEN was added initially at a dose of 10mg/day with weekly escalations to 20mg, 50mg, 100mg, 200mg to a final dose of 400mg/day. After the initial 3 patients when there was no sign of tumour lysis syndrome (TLS) the starting dose of VEN was amended to 20mg/day. The primary end-point of the trial is MRD eradication (defined as less than 1 CLL cell in 10,000) in the bone marrow after 12 months of IBR+VEN. Key secondary end-points are MRD eradication from the bone marrow after 6 and 24 months of combined IBR and VEN as well as the safety of the combination. Important safety events that were considered critical were the incidence of laboratory and clinical TLS. All patients were given prophylactic treatment with uric acid reducing agents beginning at least 72 hours prior to their initial dose of VEN. Over the first three months of combined therapy the level of CLL in the peripheral blood was monitored weekly during VEN escalation and then monthly thereafter. 50 participants will be treated in total.
Results: A total of 35 patients have been recruited between May 2016 and January 2017. To date 21 patients have completed the dose escalation period of VEN in combination with IBR. To date there has been only a single case of laboratory TLS in a patient whose phosphate (1.21 to 1.48mmol/l) and creatinine (75 to 146 umol/l) both increased when VEN was increased from 100mg to 200mg. Dosing of VEN was interrupted for 7 days (due to the logistics of clinic closure periods over the Christmas break) and IBR for 24 hours. The biochemical abnormalities resolved within 24 hours and the patient subsequently escalated to 400mg/day of VEN with no further TLS. As yet there have been a total of 5 SAEs and 22 AE's of special interest with notably lung infection (n=3) and neutropenia (n=11) occurring on more than one occasion. All SAE's resolved with appropriate management and all patients remained on therapy. No SUSAR's have been reported and no AE's have been fatal. The level of CLL in the peripheral blood increased during the 8 weeks of IBR monotherapy at 420mg/day from a median of 50 x 10^9/l (range: 0 to 330) to 55 x 10^9/l (range: 0 to 237) and then fell during the first 8 weeks of combined IBR with VEN (4 weeks dose escalation followed by 4 weeks at 400mg/day) from a median of 55 x 10^9/l to a median of 0.017 x 10^9/l (range; 0 to 3.1). The rate of fall is rapid in all patients with a median of 3 log reduction in CLL level after 8 weeks of combined therapy.
Summary/Conclusions: The combination of IBR with VEN is well tolerated in relapsed, refractory CLL with to date only a single case of laboratory TLS. The rapid reduction in the peripheral blood CLL level even during the escalation phase of VEN with IBR is promising and suggests a potent synergy between the drugs. The initial bone marrow responses are expected after 6 months of combination therapy.

States, [3]Universitätsklinikum Köln, Cologne, Germany, [4]University Hospital, Technische Universität Dresden, Dresden, Germany, [5]St James's University Hospital, Leeds, United Kingdom, [6]Peter MacCallum Cancer Centre, [7]Royal Melbourne Hospital, Melbourne, Australia, [8]Stanford University Medical Center, Stanford, CA, United States, [9]Jagiellonian University, Kraków, Poland, [10]Royal North Shore Hospital, Sydney, Australia, [11]University of Arizona, Tucson, AZ, United States, [12]Klinikum Schwabing, Munich, Germany, [13]Dana-Farber Cancer Institute, Boston, MA, United States, [14]University Hospital of Schleswig-Holstein, Kiel, Germany, [15]UT MD Anderson Cancer Center, Houston, TX, United States

Background: Venetoclax monotherapy in patients (pts) with relapsed/refractory CLL harboring deletion 17p (del17p) resulted in an ORR of 79% with a CR rate of 7% as determined by an independent review committee at the initial analysis of the pivotal M13-982 trial (n=107). Subsequently, 51 additional pts were enrolled in a safety expansion cohort.
Aims: To present results from the full trial, including minimal residual disease (MRD) status by both flow cytometry and next generation sequencing (NGS).
Methods: Pts received venetoclax 400 mg daily after initial standard ramp-up until PD or discontinuation due to other reasons. CT scan was mandatory at week 36, after which disease assessment was by clinical evaluation. MRD assessment was performed beginning with the first clinical assessment of CR or PR with nodes <2 cm and then every 12 weeks until MRD negativity (defined at 10^{-4} sensitivity). MRD was assessed by NGS and multicolor flow cytometry and the best response was reported. Data cutoff date was 10 June 2016.
Results: Pts (N=158) had a median age of 67 (range, 29–85) years; a median of 2 prior therapies (range, 0–10); 32% were fludarabine refractory; 11% had previously received a B-cell receptor signaling inhibitor (BCRi); 48% had nodes ≥5 cm; and 78% had unmutated *IGHV*. The median duration of venetoclax therapy was 16.7 (range 0–34.4) months. Primary reasons for discontinuation (50.6% of pts) were PD (31.0%), adverse events (AEs) (12.6%), withdrawal of consent (2.5%), stem cell transplant (2.5%), and other (1.9%). For all 158 pts, the investigator-assessed ORR was 77% and CR rate was 18%. The 24-month estimates for progression-free survival (PFS) and overall survival (OS) were 52% and 72%, respectively. The safety expansion cohort included 5 pts with previously untreated del(17p) CLL. These pts had an ORR of 80%, CR rate of 40%, and all 5 were alive and progression-free 1 year after the start of study treatment. Among the 18 pts with prior BCRi treatment, ORR was 61% and CR was 11%, with 12-month PFS and OS estimates of 50% and 72%, respectively. The most commonly reported AEs were neutropenia (42%), nausea (37%), diarrhea (37%), anemia (24%), and fatigue (22%). The most common grade 3–4 AEs were neutropenia (39%), thrombocytopenia (15%), and anemia (14%). Infection rate (77% all grades, 22% grade 3–4) and spectrum were consistent with the underlying disease. The rate of laboratory tumor lysis syndrome (TLS) was 5%, with no cases of clinical TLS. Of 101 pts with evaluable blood MRD by flow cytometry, 76 also had MRD data by NGS. From the full trial cohort of 158 pts, 42 (27%) demonstrated blood MRD negativity at 10^{-4} by flow cytometry, and 28 had a contemporaneous NGS sample. MRD negativity (10^{-4} sensitivity) was confirmed by NGS in 20 pts (71%), and 8 pts (29%) were MRD-positive by NGS. MRD negativity by NGS ($\leq 10^{-4}$) was observed in 22 pts in blood; 9 pts were also negative in the marrow although not necessarily at the same time. One pt negative by NGS did not have a matching flow cytometry assessment and 1 pt was positive by flow cytometry (0.008% *vs* 0.02%). Pts who achieved blood MRD-negative CR by flow cytometry (n=19) had a 24-month PFS estimate of 100%, compared with 78.5% pts who had blood MRD-negative PR (n=23). Similar results were obtained when assessed by NGS.
Summary/Conclusions: Venetoclax monotherapy resulted in a high response rate that was durable in this high-risk population, including among pts who had previously received a BCR inhibitor. MRD negativity by either flow cytometry or NGS correlated with outstanding outcomes.

S772

CHEMO-FREE TRIPLET COMBINATION OF TGR-1202, UBLITUXIMAB, AND IBRUTINIB IS WELL TOLERATED AND HIGHLY ACTIVE IN PATIENTS WITH ADVANCED CLL AND NHL

L. Nastoupil[1,*], M.A. Lunning[2], J.M. Vose[2], M.T. Schreeder[3], T. Siddiqi[4], C.R. Flowers[5], J.B. Cohen[5], J.A. Burger[1], W.G. Wierda[1], S. O'Brien[6], P. Sportelli[7], H.P. Miskin[7], M.A. Purdom[7], M.S. Weiss[7], N. Fowler[1]
[1]MD Anderson Cancer Center, Houston, [2]University of Nebraska Medical Center, Omaha, [3]Clearview Cancer Institute, Huntsville, [4]City of Hope National Medical Center, Duarte, [5]Emory University/Winship Cancer Institute, Atlanta, [6]University of California Irvine Cancer Center, Orange, [7]TG Therapeutics, Inc., New York, United States

Background: Novel targeted agents are emerging for B-cell malignancies, but few studies have safely combined these agents. Ublituximab (UTX) is a novel glycoengineered mAb targeting a unique epitope on the CD20 antigen. TGR-1202 is a next generation, once daily, PI3Kδ inhibitor, demonstrating a favorable safety profile compared to prior inhibitors, including in long-term follow up (Burris, 2016).
Aims: This Ph 1 trial evaluates the safety/efficacy of the triplet combination of a novel anti-CD20 mAb+PI3Kδ+BTK inhibitor (ibrutinib) in pts with B-cell malignancies.
Methods: Eligible pts had CLL or rel/ref NHL w/o limit to prior therapies, including those ref to prior PI3Kδ or BTK inhibitors. UTX dosed on D 1, 8, 15 of C 1, D 1 of C 2-6, and C 9 & 12. TGR-1202 dose escalated (400/600/800mg QD), ibrutinib dosed at 420mg (CLL) or 560mg (NHL), both on C1D1.
Results: 38 pts were enrolled: 20 CLL/SLL and 18 NHL, including 6 follicular (FL), 6 DLBCL, 4 mantle cell (MCL) and 2 marginal zone (MZL). Med age 65 yrs (range 32-85); 29 M/9 F; med prior tx=3 (range 0-6). 2 pts ref to prior PI3Kδ /2 prev treated with ibrutinib (1 ref/1 rel). MTD was not reached. Most common (>20%) all causality AE's were fatigue (42%), diarrhea (39%), dizziness (34%), nausea (32%), neutropenia, pyrexia, rash, infusion reaction, insomnia (each at 29%), thrombocytopenia, cough (each at 26%), anemia (24%) and sinusitis (21%). GR 3/4 AE's (all causality) were minimal, the only event >10% was neutropenia (16%). ORR amongst 36 evaluable pts is shown in the following Table 1.

Table 1.

Subtype	N	CR	PR	ORR
CLL/SLL	19	3	16	100%
FL/MZL	7	2	4	86%
DLBCL	6	0	1	17%
MCL	4	1	3	100%

53% of evaluable CLL pts had high-risk cytogenetics and 4/6 DLBCL pts were non-GCB. One CLL pt (17p/11q del) ref to PI3Kδ and ibrutinib achieved a CR. Med time on study is 10 mos (range 1-27 mos). Med DOR not reached (range 3-24 mos).
Summary/Conclusions: This is the first known triplet combination of an anti-CD20 mAb+PI3Kδ+BTK inhibitor. The combination of UTX, TGR-1202, and ibrutinib has been well tolerated with activity observed across heavily pre-treated and high-risk B-cell malignancies. Expansion cohorts at the highest dose (800mg TGR-1202+full dose ibrutinib) are underway. Future trials for the triplet are warranted.

S773

THE DUAL SYK/JAK INHIBITOR CERDULATINIB DEMONSTRATES COMPLETE INHIBITION OF SYK AND JAK AND RAPID TUMOR RESPONSES IN A PHASE 2 STUDY IN PATIENTS WITH RELAPSED/REFRACTORY B CELL MALIGNANCIES

P. Hamlin[1,*], C. Farber[2], T. Fenske[3], J. Khatcheressian[4], C. Miller[5], J. Munoz[6], M. Patel[7], S. Smith[8], D. Stevens[9], A. Pandey[10], M. Birrell[10], J. Leeds[10], Y.L. Wang[11], G. Coffey[10], J. Curnutte[10]
[1]Memorial Sloan Kettering Cancer Center, New York, [2]Carol G. Simon Cancer Center, Morristown, NJ, [3]Division of Hematology & Oncology, Medical College of Wisconsin, Milwaukee, WI, [4]Virginia Cancer Institute, Richmond, VA, [5]St. Agnes Hospital Cancer Center, Baltimore, MD, [6]Banner MD Anderson Cancer Center, Gilbert, AZ, [7]Florida Cancer Specialists/Sarah Cannon Research Center, Sarasota, FL, [8]University of Chicago, Chicago, IL, [9]Norton Cancer Institute, Louisville, KY, [10]Portola Pharmaceuticals, South San Francisco, [11]Department of Pathology, University of Chicago, Chicago, IL, United States

Background: Subsets of B cell malignancies are addicted to B cell antigen receptor (BCR) signaling for survival. Co-stimulation of the BCR with IL-2 or IL-4 in normal B cells significantly enhances cellular activation relative to BCR or cytokine stimulation alone, and combining SYK selective and JAK selective inhibitors synergize to suppress this response (Coffey et al., 2013). Hence, BCR/SYK and cytokine JAK/STAT signals cooperate to control B cell activation. This cooperation appears to be relevant to B cell malignancies as well. IL-4 promotes the survival of CLL cells in culture via up-regulation of MCL1 and BCL_{XL}, protecting the tumor from death induced by fludarabine and chlorambucil (Steele et al., 2010) and by idelalisib and ibrutinib (Aguilar-Hernandez et al., 2016). Also, unlike ibrutinib, combined SYK and JAK inhibition by cerdulatinib induces apoptosis in primary CLL cells and leads to down-regulation of MCL1 and BCL_{XL} (Blunt et al., 2015) and induces apoptosis in cells from ibrutinib-resistant CLL patients (Guo et al., 2017). It also induces apoptosis in primary DLBCL and DLBCL cell lines that carry BCR pathway mutations resistant to ibrutinib (Ma et al, 2015). Combined SYK/JAK inhibition may therefore represent a powerful strategy to control B cell malignancies. A phase I dose escalation study of cerdulatinib in 43 patients with relapsed/refractory CLL and NHL was recently completed (Hamlin et al., EHA Congress 2016). Inhibition of both BCR/SYK and JAK/STAT signaling pathways by >90% in peripheral blood assays was well tolerated. Durable PRs and 1 CR were observed in CLL and FL, including in patients who had relapsed on prior BCR inhibitor therapy. No consistent hepatic toxicity, anemia, thrombocytopenia or neutropenia was observed. Two grade 3 dose limiting toxicities were observed at 45 mg BID (fatigue, pancreatitis). 35 mg BID was identified as the Phase 2 dose based on Phase 1 data and on PK/PD modeling.
Aims: The primary aim of the study was to understand the safety and activity of cerdulatinib in B-cell malignancies.
Methods: This is an open-label study with 28-day cycles. Twice daily (BID; 30

mg and 35 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

Results: A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 tFL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3+ AEs occurring in more than 1 patient are infection (5 patients), abdominal pain (3 patients) and hypertension (3 patients). As seen in phase 1, significant inhibition of SYK and JAK signaling pathways in peripheral blood is observed. Evidence for tumor cell mobilization to peripheral blood in CLL/SLL is consistently observed following one week of therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL and 3 of 6 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug with 4 patients in response for greater than 6 months. In addition, PRs have been seen in patients who relapsed on ibrutinib (FL patient, 8+ months) and venetoclax (SLL patient, 7+ months) therapy. As demonstrated preclinically, we have seen evidence of apoptosis (Annexin V+ B-cells) in 6 CLL patients. 5 of these patients had a PR at the end of the 2nd cycle (Figure 1).

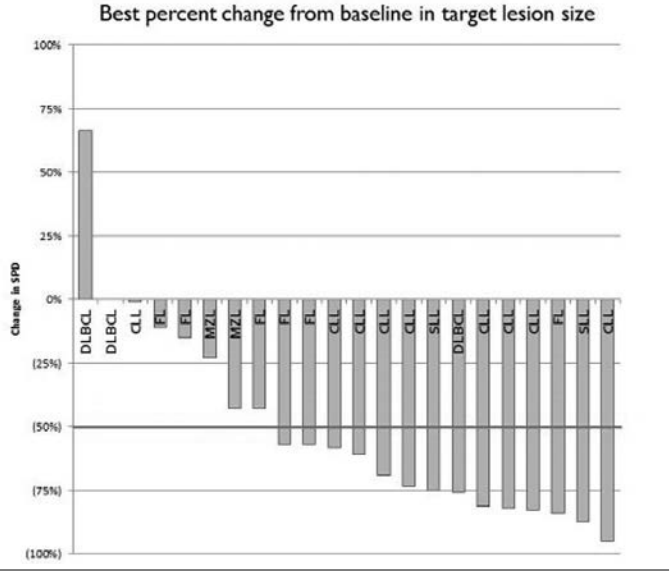

Figure 1.

Summary/Conclusions: Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Consistent activity is seen in patients with CLL and FL. Accrual is proceeding; updated PK/PD, safety and efficacy will be presented.

Follicular lymphoma - Clinical

COMPARISON OF CONTRAST-ENHANCED CT-BASED RESPONSE WITH PET ASSESSMENT AFTER FIRST-LINE THERAPY FOR FOLLICULAR LYMPHOMA IN THE PHASE III GALLIUM STUDY

J. Trotman[1,*], S. Barrington[2], D. Belada[3,4], M. Meignan[5], R. MacEwan[6], C. Owen[7], V. Ptáčník[8], A. Rosta[9], G. Fingerle-Rowson[10], F. Mattiello[10], T. Nielsen[10], D. Sahin[10], W. Hiddemann[11], R. Marcus[12], A. Davies[13]
[1]Haematology Department, Concord Repatriation General Hospital, University of Sydney, Sydney, Australia, [2]KCL and Guys' & St Thomas PET Imaging Centre, Division of Imaging and Biomedical Engineering, Kings College London, London, United Kingdom, [3]4th Department of Internal Medicine – Hematology, University Hospital Hradec Kralove, Hradec Kralove, [4]Faculty of Medicine, Charles University, Prague, Czech Republic, [5]Service de Médecine Nucléaire, Hôpital Henri Mondor and Université Paris Est Créteil, Créteil, France, [6]University of Alberta, Cross Cancer Institute, Edmonton, [7]Foothills Medical Centre and Tom Baker Cancer Centre, Calgary, Canada, [8]Department of Nuclear Medicine, First Faculty of Medicine, Charles University, Prague, Czech Republic, [9]Department of Medicine, National Institute of Oncology, Budapest, Hungary, [10]Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, [11]Ludwig-Maximilians-University Munich, Munich, Germany, [12]Department of Haematology, Kings College Hospital, London, [13]Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom

Background: Published data show ^{18}F-FDG PET-CT (PET) is predictive after first-line immunochemotherapy in advanced-stage symptomatic FL, and PET is now the recommended modality for response assessment. However, no large-scale prospective comparison of the value of standard contrast-enhanced CT *vs* PET response has been performed.

Aims: To compare CT and PET response assessment for FL pts in the prospective Phase III GALLIUM study, which evaluated chemotherapy plus obinutuzumab (G-chemo) or rituximab (R-chemo) induction followed by maintenance antibody therapy (Marcus 2016).

Methods: PET scans, introduced after an early protocol amendment (July 2011), were performed at baseline and end of induction (EOI; all pts gave informed consent) and assessed by the investigator (INV) and an independent review committee (IRC) comprising two radiologists, with a third adjudicator; final response was determined by a clinician. Response was assessed by CT and PET plus bone marrow biopsy, applying the revised International Working Group (IWG) criteria (Cheson 2007, Juweid 2007). Complete remission (CR) status at EOI for each assessment, CT-CR and PET-CR, was compared with pt characteristics, PFS and OS.

Results: Among 1202 ITT pts with FL enrolled in GALLIUM, IRC-assessed CT showed a CR in 330 pts (27.5%), PR in 747 (62.1%), SD in 20 (1.7%), PD in 35 (2.9%), unavailable (NA) in 48 (4.0%) and unevaluable (NE) in 22 (1.8%). Of 609 pts with a baseline PET scan, 595 had detectable lesions, and 535 also had an evaluable PET at EOI. Baseline demographics and disease characteristics were similar in PET and non-PET populations. Pts with NA (n=52) or NE (n=8) scans were considered non-responders; these pts and those with PD prior to EOI were excluded from landmark PFS analyses. At EOI, 390/595 (65.5%) pts achieved a PET-CR according to IRC, comprising 212/297 (71.4%) G-chemo pts and 178/298 (59.7%) R-chemo pts. However, for these 390 pts, evaluable CT responses were 161 CR (41.3%), 216 PR (55.4%) and 5 SD/PD (1.3%; Table 1). Conversely, PET assessment showed a PET-CR in 161/177 (91.0%) of pts achieving a CT-CR, and PET-PR in only 117/362 (32.3%) of pts with CT-PR. Concordance between CT and PET assessment was 52.6% for IRC and 54.1% for INV. Concordance between INV and IRC evaluation was 71.9% for CT and 68.6% for PET. After a median follow-up of 34.5 mo (range 0–54.5), IRC-PET status was highly predictive of PFS (PET-CR *vs* PET non-CR: HR 0.39; 95% CI 0.25–0.60; p<0.0001) and OS (HR 0.41; 95% CI 0.19–0.86; p=0.018). 2.5-yr PFS from EOI was 87.6% (95% CI 83.5–90.8) for PET-CR pts compared with 70.9% (95% CI 61.3–78.6) for PET non-CR pts; corresponding OS was 96.6% (95% CI 94.1–98.1) *vs* 90.9% (95% CI 84.7–94.6) (Figure 1).

Table 1. CT and PET clinical response assessment by IRC at EOI

PET, n (%)	CT, n (%)					
	CR	PR	SD	PD	NE	NA
CR	161 (27.1)	216 (36.3)	4 (0.7)	1 (0.2)	7 (1.2)	1 (0.2)
PR	7 (1.2)	117 (19.7)	1 (0.2)	1 (0.2)	1 (0.2)	
SD			4 (0.7)			
PD	2 (0.3)	3 (0.5)	1 (0.2)	8 (1.3)		
NE	2 (0.3)	1 (0.2)			5 (0.8)	
NA	5 (0.8)	25 (4.2)	1 (0.2)	2 (0.3)	1 (0.2)	18 (3.0)

Summary/Conclusions: This large prospective analysis confirms EOI PET as an early predictor of PFS and OS in FL, with good concordance between INV

and IRC PET evaluation. Comparison of PFS based on CT-response and re-analysis of PET scans applying the now recommended 5-point scale for PET response assessment will be presented. Pooled analyses of these and data from other studies with longer follow-up may determine PET response as a reliable early surrogate for PFS and OS, providing a platform for study of response-adapted therapy.

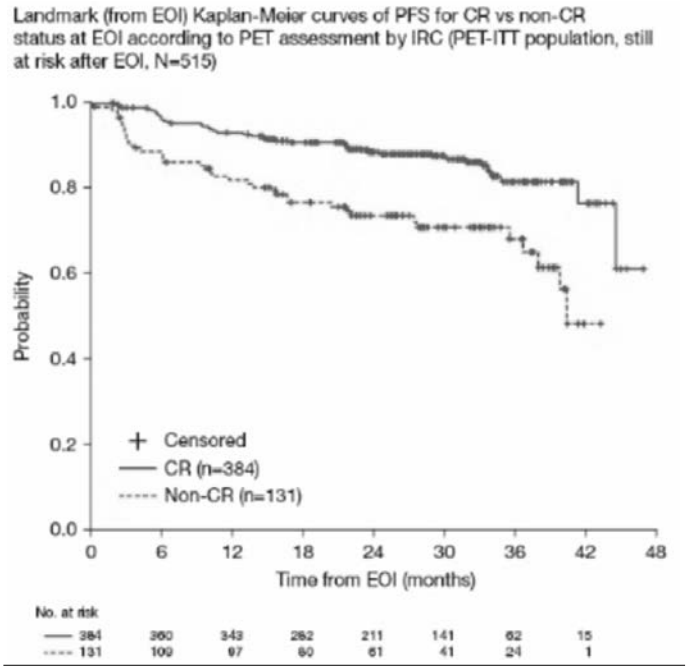

Figure 1.

Hoffmann-La Roche Ltd, Basel, Switzerland, [11]The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, [12]Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, [13]Pharma Development Safety and Risk Management, [14]Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, [15]Department of Haematology, Kings College Hospital, London, United Kingdom

Background: The Phase III GALLIUM study (NCT01332968) showed that obinutuzumab (GA101; G) significantly prolonged PFS in previously untreated FL pts relative to rituximab (R) when combined with chemotherapy (chemo; CHOP, CVP or bendamustine [B]). Grade 3–5 and serious AEs were more common with G-chemo.

Aims: To explore outcomes by immunochemotherapy regimen.

Methods: Pts were aged ≥18 yrs with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG PS 0–2, and requiring treatment according to GELF criteria. Chemo regimen was allocated by center. Pts were randomized 1:1 (stratified by chemo, FLIPI-1 group and geographic region) to R 375mg/m2 on day (D) 1 of each cycle (C) or G 1000mg on D1, 8 and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo. Pts with CR or PR at EOI (per Cheson 2007) continued to receive R or G every 2 months for 2 yrs or until progression. The cut-off date for this analysis was September 10 2016. All pts gave informed consent.

Results: 1202 FL pts were randomized. Baseline characteristics were generally similar across chemo groups, although B and CVP pts had relatively more comorbidities, *e.g.* GI and vascular disorders, than CHOP pts. After 41.1 months' median follow-up, investigator (INV)-assessed PFS remained superior for G-chemo relative to R-chemo (HR, 0.68; 95% CI 0.54–0.87; p=0.0016) with consistent HRs across chemo groups (Figure 1). HRs for secondary time-to-event endpoints were supportive of the primary analysis. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and R arms for CHOP and CVP but not for B. In all chemo groups, SAEs were more frequent with G than R, and AEs causing treatment discontinuation and fatal AEs were similar. Reductions in T-cell counts were more pronounced and prolonged in the B group than CHOP or CVP groups.

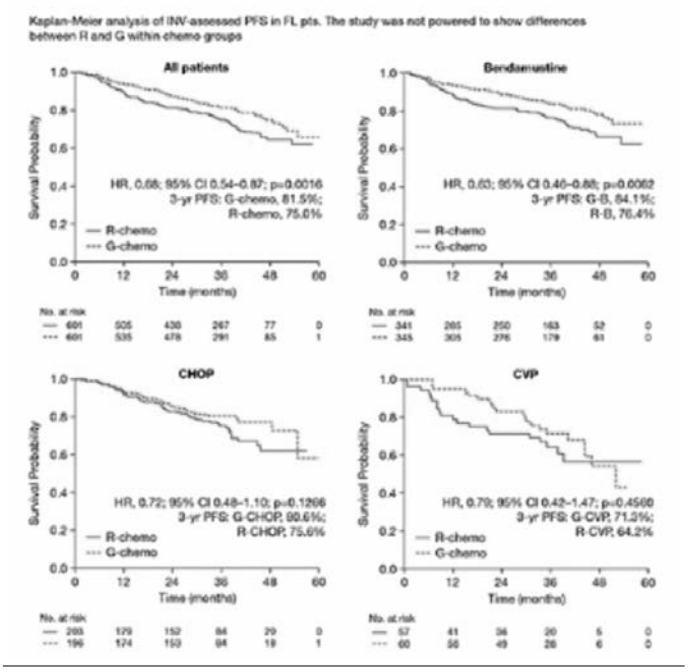

Figure 1.

Table 1. Safety summary (number (%) of FL pts* with ≥1 AE).

	G-B(n=338)	R-B(n=338)	G-CHOP(n=193)	R-CHOP(n=203)	G-CVP(n=61)	R-CVP(n=56)	G-chemo(n=595)	R-chemo(n=597)

Febrile neutropenia†	18(5.3)	13(3.8)	22(11.4)	14(6.9)	2(3.3)	2(3.6)	42(7.1)	29(4.9)
AEs of special interest by category								
Grade 3–5 Infections‡	89(26.3)	66(19.5)	23(11.9)	24(12.4)	8(13.1)	7(12.5)	121(20.3)	98(16.4)
Second neoplasms§	37(10.9)	23(6.8)	9(4.7)	11(5.4)	1(1.6)	2(3.6)	47(7.9)	36(6.0)
SAEs	176(52.1)	160(47.3)	76(39.4)	67(33.0)	26(42.6)	19(33.9)	281(47.2)	246(41.2)
Fatal AEs	20(5.9)	16(4.7)	3(1.6)	4(2.0)	1(1.6)	1(1.8)	24(4.0)	21(3.5)
AEs causing Tx discontinuation	52(15.4)	48(14.2)	32(16.6)	31(15.3)	11(18.0)	9(16.1)	98(16.5)	88(14.7)

*Pts who received ≥1 dose of study drug. Three pts received G but no chemo; †Occurring in >10% of pts in any group; ‡MedDRA SOC 'Infections and Infestations'; §Malignant or unspecified tumors occurring >6 mo after first study drug intake

Summary/Conclusions: In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma (iNHL) subtype, yet treatment options in the relapsed/refractory setting are limited. Copanlisib is a potent and selective pan-class I PI3K inhibitor with predominant activity against the δ- and α-isoforms.
Aims: We report results from the FL subset of a large phase II study in iNHL patients (NCT01660451, part B).
Methods: Patients with histologically confirmed indolent indolent FL (grade 1-3a) relapsed/refractory to ≥2 prior lines of treatment were treated with copanlisib (60 mg IV infusion) administered on days 1, 8 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) as assessed by independent radiology review according to the response criteria for lymphoma (Cheson et al, JCO 20:579, 2007). Secondary endpoints included progression-free survival (PFS) and duration of response (DOR), safety and tolerability.
Results: A total of 141 patients with iNHL were treated in the phase II study, including 104 patients with FL. The FL subset was characterized as: 52% male, 83% white, median age 62 yrs, 62% ECOG 0, 63% refractory to last therapy, median time from most recent progression 8 wks (range 1-73) and median prior lines of therapy 3 (range 2-8). At the time of primary analysis the ORR was 58.7%, comprising 15 patients (14.4%) with complete response and 46 (44.2%) with partial response. Stable disease was observed in 35 (33.7%) patients and progression of disease as best response in 2 patients. The median duration of response was 370 days (range 0-687), with 43 responders censored at data cut-off. Median duration of treatment was 22 wks (range 1-105); 33 (32%) patients remained on treatment. Per investigator assessment, 87 of 96 evaluable patients (91%) had some degree of tumor shrinkage as best response, and 58/96 (60%) had >50% tumor shrinkage (Figure 1). For all patients in the phase II study, the most common treatment-emergent AEs occurring in >25% of patients included (all grade/grade 3+): diarrhea (34%/5%), reduced neutrophil count (30%/24%), fatigue (30%/2%), and fever (25%/4%). Hyperglycemia (50%/41%) and hypertension (30%/24%) were transient. The incidence of pneumonitis (8%/1.4%), hepatic enzymopathy (AST 28%/1.4%; ALT 23%/1.4%), opportunistic infection (1.4%) and colitis (0.7%) were low. Six deaths were observed, 3 of which were attributed to copanlisib: one lung infection, one respiratory failure, and one thromboembolic event.

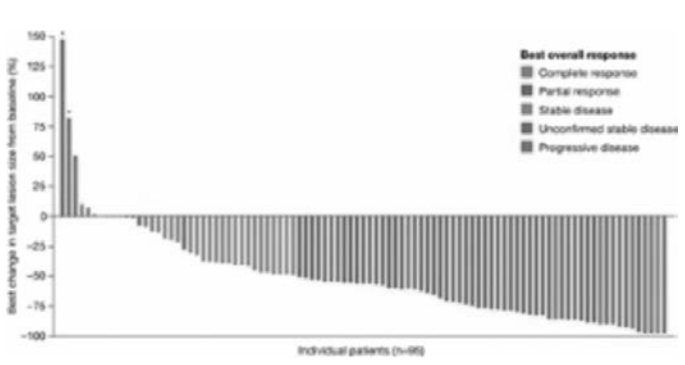

Figure 1.

Summary/Conclusions: Copanlisib was highly active as a single agent in heavily pretreated relapsed/refractory FL patients and resulted in responses in the majority of patients, with a median duration of response exceeding one year. Toxicities were manageable, with a low incidence of severe AEs associated with other PI3K inhibitors, especially hepatic enzymopathy, opportunistic infections, and colitis.

Ematologia, Varese, Italy, [8]Florida Cancer Specialist - Fort Myers, Fort Myers, United States, [9]University of Liverpool, Liverpool, United Kingdom, [10]Semmelweis Egyetem, I. sz. Belgyogyaszati Klinika, Budapest, Hungary, [11]CHU Estaing - Service d'hématologie, Clermont-Ferrand, France, [12]Centre intégré de santé et de services sociaux de l'Outaouais, Quebec, Canada, [13]Tennessee Oncology, Nashville, United States

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib monotherapy in a double refractory iNHL population, which included a majority of patients (pts) with follicular lymphoma (FL).
Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety of duvelisib.
Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double-refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25 mg BID in 28-day treatment cycles until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs) and other safety parameters. *Pneumocystis jiroveci* pneumonia (PJP) prophylaxis was mandated for all pts.
Results: 129 pts with iNHL were treated on study. Of these, 83 pts with FL received duvelisib with a median duration of exposure of 6 mo. (range: 0.4 - 24). Median age was 64 years; 68% were male. Most FL pts had an ECOG performance status score at baseline of 0 (51%), followed by 1 (42%) and 2 (7%). Most FL pts (65%) had a FLIPI score at baseline ≥3, and most had either Stage 3 (46%) or Stage 4 (39%) disease. Median time from last anticancer therapy to first dose of duvelisib was 3.2 months. FL pts received a median of 3 prior anticancer regimens (range: 1 - 10); 65% of pts received ≥3 prior regimens, 17% ≥6 prior regimens. The ORR was 41% (CI: 30, 52), all of which were PRs. 36% of pts had SD as best response, and 17% had PD as best response. 6% of pts were not evaluable, as they only had a baseline scan. Median TTR was 1.9 mo. (range: 1.6 - 11.7). 80% of FL pts experienced a reduction in nodal target lesions after treatment with duvelisib. Among the 34 FL pts with a response per IRC, the median DoR was 9.2 months. The median PFS for all FL pts was 8.3 months, while the median OS was 11.1 months. Among all pts treated on study (n=129), AEs were mostly Gr 1-2. Most common ≥Gr 3 AEs were transient cytopenias [neutropenia (23%), anemia (12%), and thrombocytopenia (10%)] and diarrhoea (15%). 17% of pts discontinued duvelisib due to an AE. Opportunistic infections occurred in <5% of pts, none were fatal, and included 1 pt (0.8%) with *pneumocystis* and 3 pts (2.3%) with CMV infections. Six pts had an AE with a fatal outcome.
Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory FL population (41% ORR, median DoR 9.2 mo., 80% with reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy has a favorable benefit-risk profile in double-refractory iNHL, and may represent an important treatment option. Updated clinical data will be available at the time of presentation.

Background: Between March 2000 and May 2005 a multicenter randomized trial comparing frontline use of CHOP-R *vs* R-HDS with autograft has been performed on 134 Follicular Lymphoma (FL) patients, selected for age less than 60 yrs. and poor prognostic features according to age-adjusted IPI (2-3) and IIL-score (3 or greater). Results at 4-yr follow-up were previously published (Ladetto M et al, Blood 2008), showing superior disease control with R-HDS without any survival advantage.
Aims: We have recently performed a long term update and the results at a median follow-up of 13 yrs are here presented.
Methods: The long-term outcome has been updated for 119 out of the original 134 randomized patients (56 CHOP-R and 63 R-HDS arms). Main features of the updated patients included: median age 51 yrs. (22-60), M/F ratio 68/51, aaIPI 2-3 90%, high LDH 43%, bulky disease 60%, B-symptoms 46%, BM involvement 86%; no significant differences were observed in clinical presentation between the two arms, as previously reported. Treatment schedule consisted of: i. CHOP-R arm: 6 courses of cyclophosphamide/doxorubicin/vincristine/prednisone followed by 4-weekly rituximab courses; ii. experimental R-HDS arm: rituximab with high-dose sequential chemotherapy followed by autografting. The analysis was intention to treat with event-free survival as the primary endpoint. Minimal residual disease (MRD) was evaluated post treatment in 56 patients with a bcl-2/IgH MBR or mcr translocation confirmed at diagnosis by nested PCR. The trial was registered at www.clinicaltrials.gov, no. NCT00435955. The long-term outcome has been updated in January 2017 by 27 out of 30 participating Centers, on 119 patients (88% of the whole series).
Results: Complete remission (CR) was achieved by 86 (72%) patients, including 32 (57%) with CHOP-R and 54 (85%) with R-HDS (p <.001); Molecular Remission (MR) was achieved in 37 out of 56 (66%) evaluable patients. At a median follow-up of 13 yrs., 74 patients (63%) are alive. Overall, 22 patients died for lymphoma progression (13 CHOP-R, 9 R-HDS), 12 died for secondary malignancy (3 in the CHOP-R, 9 in the R-HDS arms), 11 patients died for other causes, including four early toxic deaths. The overall survival (OS) for the whole series is 63% at 13 yrs, as shown in Figure 1A. No significant differences in the long-term OS were observed between the two arms, with 13-yr survival of 65% and 61% for CHOP-R and R-HDS, resppectively (p=0.51). At 13 years, the event free survival is 35%, whereas the disease-free survival (DFS) is of 53%, as shown in Figure 1B. Response to induction therapy had a major impact on the OS, with 13 yr survival of 75% for patients achieving CR *vs* 33% for those with less than CR (p <.001). Similarly, Molecular Remission (MR) achievement was associated with prolonged OS, with 13 yr survival of 81% for patients in MR on BM cells, and of 47% for those with positive MRD (p=.02) (Figure 1C).

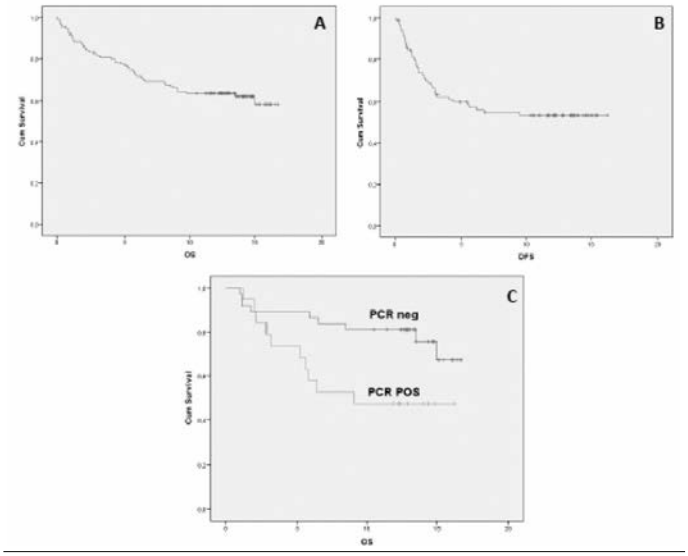

Figure 1.

Summary/Conclusions: i. poor risk FL may have a prolonged survival, with 63% of patients alive at 13 yrs.; ii. no survival differences between CHOP-R and R-HDS can be detected even at 13 yrs of follow-up; iii. achieving CR is still crucial for the long-term survival; iv. the MRD analysis has a prognostic impact not only on progression-free but also on OS; v. lymphoma progression remains the major cause of death, while secondary neoplasms represent the second cause of treatment failure; vi. a subgroup of advanced-stage FL may experience a prolonged DFS lasting at least 13 yrs: this raises the issue of the potential curability of FL.

Changing the strategy of therapy in multiple myeloma

S779

PHASE II TRIAL OF COMBINATION OF ELOTUZUMAB, LENALIDOMIDE, AND DEXAMETHASONE IN HIGH-RISK SMOLDERING MULTIPLE MYELOMA

[1]Multiple Myeloma, Dana-Farber Cancer Institute, [2]Blood Cancer Research Partnership, Boston, [3]Multiple Myeloma, University of Maryland Greenebaum Cancer Center, Baltimore, [4]Multiple Myeloma, Colorado Blood Cancer Institute, Denver, [5]Multiple Myeloma, Beth Israel Deaconess Medical Center, [6]Multiple Myeloma, Massachusetts General Hospital, Boston, [7]Multiple Myeloma, Eastern Maine Medical Center, Bangor, [8]Multiple Myeloma, Levine Cancer Institute, Charlotte, [9]Multiple Myeloma, St. Francis Hospital, Hartford, [10]Multiple Myeloma, Newton-Wellesley Hospital, Newton, [11]Multiple Myeloma, Barbara Ann Karmanos Cancer Institute, Detroit, [12]Multiple Myeloma, University of Chicago Medical Center, Chicago, United States

Background: This study aimed to determine the benefit of early therapeutic intervention with the combination of elotuzumab, lenalidomide, and dexamethasone in patients with high-risk smoldering multiple myeloma (SMM).
Aims: The overarching objective of this trial is to determine progression free survival to symptomatic myeloma (MM). Furthermore, the study examined whether genomic studies can help in determining patients who would benefit the most from this early therapeutic intervention.
Methods: Patients enrolled on study met eligibility for high-risk SMM based on the newly defined criteria proposed by Rajkumar et al, Blood 2014. Patients were administered weekly elotuzumab (10 mg/kg) on days 1, 8, 15, and 22 for the first two 28-day cycles while receiving lenalidomide on days 1-21. For cycles 3-8, patients were administered elotuzumab infusions on days 1, 8, and 15. Dexamethasone (40mg) was given on days 1, 8 and 15 for 40 of the 50 patients enrolled. After 8 cycles or best response, patients were given the option to mobilize with either cyclophosphamide or plerixafor and collect stem cells for future transplant. Patients were then allowed to continue on maintenance therapy where they were administered elotuzumab (20 mg/kg) on day 1, in combination with lenalidomide days 1-21 of a 28 day cycle. Bone marrow samples of 33 patients were obtained before starting therapy for baseline assessment and whole exome sequencing (WES) of plasma cells.
Results: In total, 50 patients were enrolled on this study from January 2015 to date, with the participation of eight sites. The median age of patients enrolled was 62 years (range 29 to 79) with 18 males (36%) and 32 females (64%). Interphase fluorescence *in situ* hybridization (iFISH) detected high risk cytogenetics in 20 patients. The median number of cycles completed is 12 (range 1 to 24). Therapy related grade 3 toxicities included hypophosphatemia (30%), neutropenia (14%), infection (12%), anemia (2%), pulmonary embolism (2%), rash (4%), and diarrhea (2%). Therapy related grade 4 toxicities included thrombocytopenia (2%), neutropenia (2%) and one instance of cholecystitis (2%). Stem cell collection was successful in all patients collected to date. Of the 31 evaluable patients that completed the first 8 cycles of therapy, the overall response rate was 84%, including 2 complete responses (7%), 11 very good partial responses (36%) and 13 partial responses (42%), and a clinical benefit rate of 100%. None of the patients showed progression to overt MM to date. WES was performed on 25 samples at the time of initiation of therapy. Recurrent mutations in the MAPK pathway (*KRAS*, *NRAS*) and tumor suppressor gene, *TP53*, were detected in 32% of the cases (16% each), while mutations in NF-KB and plasma cell differentiation pathways were present in 10% of patients. *CCND1* gene mutation was seen in 1 patient and was associated with t(11:14) as reported in the previous WES studies of MM. CNAs were called based on WES: 1q amplification, 13q, 17p, and 1p deletions were identified in 28, 20, 16, and 12% of cases, respectively. Interestingly, in 6 patients, high-risk CNAs were not reported in iFISH but were detected by WES. Finally, we assessed the correlation between neoantigen load and clinical response.
Summary/Conclusions: The combination of elotuzumab, lenalidomide, and dexamethasone is well tolerated and demonstrates a high response rates with no progression to overt MM to date. Correlation with genomic studies can help define patients who benefit the most from this early therapeutic intervention.

S780

TWICE-WEEKLY IXAZOMIB PLUS LENALIDOMIDE-DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: LONG-TERM FOLLOW-UP DATA FOR PATIENTS WHO DID NOT UNDERGO STEM CELL TRANSPLANTATION

P. Richardson[1,*], C. Hofmeister[2], C. Rosenbaum[3], M. Htut[4], D. Vesole[5], J. Berdeja[6], M. Liedtke[7], A. Chari[8], S. Smith[9], D. Lebovic[10], N. Raje[11], E. Liao[12], X. Zhang[12], D. Berg[12], R. Baz[13]

Lee Moffitt Cancer Center & Research Institute, Tampa, United States

Background: Addition of a proteasome inhibitor to a doublet backbone therapy has been shown to improve efficacy in newly diagnosed multiple myeloma (NDMM) patients (San Miguel et al, N Engl J Med 2008, Durie et al, Lancet 2017). Data from two phase 1/2 studies indicate that the combination of ixazomib plus lenalidomide-dexamethasone (IRd) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated (Kumar et al, Lancet Oncol 2014; Richardson et al, Blood 2013).
Aims: This phase 1/2 study (NCT01383928) evaluated twice-weekly ixazomib plus Rd as induction therapy, followed by maintenance therapy with single-agent ixazomib. We report long-term efficacy and safety data in patients who did not withdraw from the study in order to receive SCT.
Methods: Patients with NDMM (SCT-eligible or SCT-ineligible) received twice-weekly oral ixazomib (3.0 or 3.7 mg on days 1, 4, 8, and 11) plus lenalidomide (25 mg on days 1–14) and dexamethasone (20 mg [10 mg in cycles 9–16] on days 1, 2, 4, 5, 8, 9, 11, and 12) for up to sixteen 21-day cycles, followed by maintenance therapy with single-agent twice-weekly ixazomib. Patients received therapy until disease progression or toxicity. Those who proceeded to SCT did not receive further ixazomib therapy. Response/progression was assessed per IMWG criteria after cycles 1, 2, 3, 4, and then every 2 cycles during induction and maintenance.
Results: Of the 64 enrolled patients, 40 continued on study treatment without early withdrawal for SCT; long-term follow-up of these 40 patients is reported here. The median age of patients was 66 years (range 34–82), and 45%/38%/18% of patients had ISS disease stage I/II/III. At a median follow-up of 47.0 months, the overall response rate (ORR; ≥partial response [PR]) in the response-evaluable population was 95%, the complete plus very good partial response (CR+VGPR) rate was 68%, and the CR rate was 32%. Median time to first response was approximately 1 cycle (0.72 months). Median time to a best response of ≥CR was 4.2 months. Patients received a median (range) of 14 (1–75) treatment cycles. Median progression-free survival (PFS) for patients not proceeding to SCT was 24.9 months. Median overall survival (OS) was not estimable; the 2-year Kaplan-Meier estimate for OS was 92%. A total of 78% of patients had grade ≥3 treatment-related adverse events (AEs); the most common treatment-related grade ≥3 AEs and serious AEs are shown in the Table 1. After completing induction therapy with IRd, 18 patients went on to receive maintenance with single-agent ixazomib on a twice-weekly dosing schedule. Patients who went on to maintenance received a median (range) of 31.5 (17–75) treatment cycles. Among the patients who received maintenance treatment, the ORR (≥PR) was 94%, the CR+VGPR rate was 89%, and the CR rate was 44%. Two (11%) patients improved their responses during maintenance (1 VGPR to stringent CR, and 1 VGPR to near-CR). Five (28%) patients who received maintenance therapy had an onset of a grade ≥3 treatment-related AE in cycle 17 or beyond. Rash (aggregate term) was infrequent with single-agent ixazomib during maintenance (1 patient, 6%).

Table 1.

Common grade ≥3 treatment-related AEs (occurring in ≥5% of patients), treatment-related serious AEs, and AEs resulting in any study drug dose reductions.

AE, n (%)	All patients who did not withdraw to receive SCT, n=40	Maintenance subset (n=18); AEs with onset during induction (cycles 1–16)	Maintenance subset (n=18); AEs with onset during maintenance (cycle ≥17)
Grade ≥3 treatment-related AEs of clinical importance			
Rash*	7 (18)	4 (22)	1 (6)
Hyperglycemia	4 (10)	2 (11)	0
Peripheral neuropathy*	4 (10)	1 (6)	1 (6)
Pneumonia	3 (8)	3 (17)	0
Hyponatremia	3 (8)	0	0
Neutropenia#	4 (10)	2 (11)	1 (6)
Serious treatment-related AEs			
All	17 (43)	8 (44)	2 (11)
AEs resulting in any study drug dose reductions†			
All	27 (68)	13 (72)	6 (33)

*MedDRA high-level term. #Pooled terms. †Reduction of at least one of the three drugs in the triplet regimen during the induction period and/or of ixazomib during the maintenance period

Summary/Conclusions: In patients with NDMM, twice-weekly ixazomib plus Rd resulted in exceptional response rates in patients who did not receive a SCT and who received maintenance therapy. The responses were deep and durable, with long PFS and a high 2-year OS estimate. The majority of AEs had an onset during induction, and the incidence of AEs during maintenance was infrequent.

Background: Immunomodulatory agents are effective therapies for multiple myeloma (MM) acting via the modulation of cereblon. Lenalidomide (Len) has fewer side effects than Thalidomide (Thal), whilst retaining the benefits of oral administration, enabling long-term treatment that has been associated with better disease control. Combinations of agents induce deeper, longer remissions by targeting different clonal populations, with triplets outperforming doublets. The optimum immunomodulatory-based induction combinations and maintenance regimens are unknown.
Aims: The UK NCRI Myeloma XI study compared triplet induction regimens of Len *vs* Thal and examined the role of post-ASCT maintenance Len *vs* observation, enabling us to explore the interaction of Len induction with Len maintenance.
Methods: Myeloma XI is a multicenter, open-label, parallel group, randomised controlled trial for newly diagnosed MM patients of all ages, with pathways for transplant eligible (TE) and non-eligible patients. For TE patients the induction question compared Len or Thal plus cyclophosphamide and dexamethasone (CRD *vs* CTD) continued for a minimum of 4 cycles and to maximum response. For patients with a suboptimal response there was a subsequent randomization to a proteasome inhibitor containing triplet or no further therapy, prior to high-dose melphalan and ASCT. A maintenance randomisation at 3 months post ASCT compared Len till disease progression with observation. High risk disease was defined as the presence of at least one of t(4;14), t(14;16), del(17p) or gain(1q). 2042 TE patients underwent the induction randomization (CRD 1021, CTD 1021). After a median follow up of 36.3 months, 965 PFS and 415 OS primary endpoint events had occurred. Secondary endpoints include response and toxicity.
Results: In TE patients, CRD induction was associated with deeper responses than CTD (≥VGPR: CRD 60% *vs* CTD 53%), a finding which persisted post ASCT (≥VGPR CRD 82% *vs* CTD 77%). This was associated with a significantly improved median PFS. Patients receiving CRD achieved a median PFS of 35.9 months compared to 32.9 for those who received CTD (HR 0.85, 95%CI [0.75, 0.96], p=0.0116). This also translated into an overall survival benefit, 3 year OS: CRD 82.9% *vs* CTD 77.0% (HR 0.77, 95%CI [0.63, 0.93], p=0.0072). There were higher rates of PN and constipation with CTD *vs* haematological toxicity with CRD. Maintenance therapy with Len was associated with a significantly longer median PFS compared to observation (TE HR 0.47, 95%CI 0.38, 0.60). This finding persisted across all subgroups including patients with high-risk disease. Exploratory analysis across the TE pathway suggested that CRD induction with Len maintenance was optimum: 60 month PFS CRD-R 50.2%, CTD-R 39.1%, CRD-obs 18.5%, CTD-obs 23.4%.
Summary/Conclusions: In TE patients CRD was associated with deeper responses than CTD and with a PFS and OS benefit. The best outcomes were associated with Len induction plus Len maintenance. Our findings support continuing Len therapy through induction until disease progression.
On behalf of the UK NCRI Haemato-oncology CSG.

S782

COMPARISON OF DENOSUMAB WITH ZOLEDRONIC ACID FOR THE TREATMENT OF BONE DISEASE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; AN INTERNATIONAL, RANDOMIZED, DOUBLE BLIND TRIAL

E. Terpos[1,*], G.D. Roodman[2], W. Willenbacher[3], K. Shimizu[4], R. García-Sanz[5], B. Durie[6], L. Zhu[7], S. Bhatta[7], N. Raje[8]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, [2]Indiana University Simon Cancer Center, Indianapolis, United States, [3]Medical University of Innsbruck, Innsbruck, Austria, [4]National Hospital Organization Higashi Nagoya National Hospital, Nagoya, Japan, [5]Hospital Universitario de Salamanca, Salamanca, Spain, [6]Cedars-Sinai Medical Center, Los Angeles, [7]Amgen Inc., Thousand Oaks, [8]Massachusetts General Hospital Cancer Center, Boston, United States

Background: Multiple myeloma is characterized by osteolytic bone disease, with up to 80% of pts presenting with detectable lesions. Myeloma bone disease is mediated by osteoclast activating factors such as RANKL, increasing the risk of skeletal-related events (SREs) and impacting morbidity and mortality. DMB, a human monoclonal antibody that targets and binds to RANKL, can be administered subcutaneously (SC) to pts regardless of renal function.
Aims: This study evaluates the efficacy and safety of DMB compared with ZA in newly diagnosed myeloma pts.
Methods: Adult pts were randomized 1:1 to DMB 120mg SC Q4W or ZA 4mg IV (adjusted) Q4W along with anti-myeloma therapy. Key stratification factors included type of first-line therapy (novel or non-novel) and previous SRE. Pts with renal insufficiency were excluded if baseline creatinine clearance (CrCl)<30mL/min. The primary endpoint was non-inferiority of DMB to ZA with respect to time to first on-study SRE. Secondary endpoints included superiority of DMB for time to first on-study SRE and first-and-subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed.
Results: A total of 1718 pts were randomized, 859 to each arm. Baseline demographics and disease characteristics were balanced, with 66.0% of DMB and 67.2% of ZA pts reporting prior SRE history; CrCl≤60mL/min was reported in 26.7% of pts. During the primary blinded treatment period (median follow-up 17.4 months [m]), 43.8% DMB pts and 44.6% ZA pts had a first on-study SRE. The median time to first on-study SRE was similar between DMB (22.83 m) and ZA (23.98 m) pts. DMB was non-inferior to ZA (P=0.01) in delaying time to first on-study SRE (HR[95%CI]=0.98[0.85,1.14]). Superiority was not demonstrated for time to first on-study SRE (P=0.82) and time to first-and-subsequent on-study SRE (P=0.84). In this high-risk study population the effect of antiresorptive therapy may only be evident later in the treatment course. A post-hoc, landmark analysis at 15 m for time to first SRE demonstrated a HR(95%CI)=0.66(0.44,0.98),P=0.039 (Figure 1) between DMB and ZA. OS was similar between DMB and ZA (HR[95%CI]=0.90[0.70,1.16],P=0.41), with fewer deaths with DMB (121[14.1%]) than ZA (129[15.0%]). PFS yielded a HR(95%CI)=0.82(0.68,0.99), descriptive P=0.036, with median times of 46.09m (95%CI:34.3,NE) for DMB and 35.38m (95%CI:30.19,NE) for ZA. The most common TEAEs(>25%) for DMB and ZA were diarrhea and nausea. The rates of SAEs (DMB,ZA [%];46.0,47.3), hypocalcemia (16.9,12.4; serious:0.9,0.2), and positively adjudicated ONJ (4.1,2.8) were comparable to known safety profiles. Fewer DMB pts (%) compared with ZA pts had AEs potentially related to renal toxicity (10.0,17.1;P<0.001), most notably in pts with baseline CrCl≤60mL/min (12.9,26.4). TEAEs led to IP discontinuation in 12.2% of all pts (12.9,11.5).

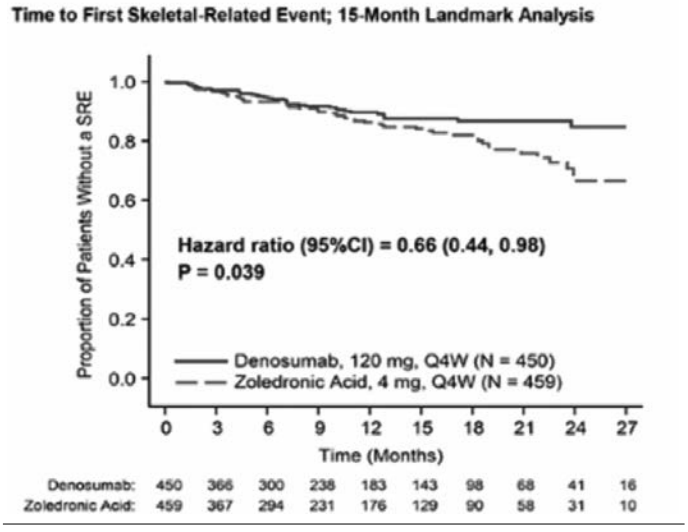

Figure 1.

Summary/Conclusions: DMB demonstrated non-inferiority to ZA in delaying time to first on-study SRE in myeloma pts, meeting the primary endpoint of the study. A landmark analysis at 15 m suggests a significant benefit for DMB with respect to time to first SRE. The rates of renal AEs were significantly lower in DMB pts while the overall rates of AEs, including hypocalcemia and ONJ, were consistent with the known DMB safety profile. The results of the landmark analysis and possible prolongation of PFS with DMB therapy is promising.

S783

PEMBROLIZUMAB PLUS LENALIDOMIDE AND LOW-DOSE DEXAMETHASONE FOR PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: EFFICACY AND BIOMARKER RESULTS FROM THE PHASE 1 KEYNOTE-023 STUDY

P. Rodriguez Otero[1,*], M.-V. Mateos[2], R. Orlowski[3], D. Siegel[4], D. Reece[5], P. Moreau[6], E.M. Ocio[2], N. Munshi[7], D. Avigan[8], R. Ghori[9], R. Wnek[9], R. Mogg[9], P. Marinello[9], J. San Miguel[1]
[1]Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada, IDISNA, CIBERONC, Pamplona, [2]Complejo Asistencial Universitario de Salamanca/IBSAL, Salamanca, Spain, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]Hackensack University Medical Center, Hackensack, United States, [5]Princess Margaret Cancer Centre, Toronto, Canada, [6]University Hospital Hotel-Dieu, Nantes, France, [7]Dana-Farber Cancer Institute, [8]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, [9]Merck & Co., Inc., Kenilworth, United States

Background: Pembrolizumab (pembro) is a humanized, highly selective, high-affinity IgG4/κ antibody that blocks the interaction between programmed death 1 (PD-1) and its ligands PD-L1 and PD-L2, activating antitumor immunity. Pembro plus lenalidomide (len) and low-dose dexamethasone (dex) may provide synergistic antitumor activity in relapsed/refractory multiple myeloma (RRMM). Biomarkers indicative of response, pharmacodynamic activity, and/or mechanism of action to combination therapies are also needed.
Aims: To determine the maximum tolerated dose (MTD) and safety and tolerability of pembro plus len and low-dose dex in patients with RRMM. Additionally PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated.
Methods: This open-label, phase 1 KEYNOTE-023 (NCT02036502) study of pembro plus len and low-dose dex enrolled patients with RRMM previously treated with ≥2 prior therapies, including both a proteasome inhibitor and an immunomodulatory drug. Patients received pembro 200 mg IV every 2 weeks (Q2W), len 25 mg orally on days 1-21, and dex 40 mg orally weekly on each 28-day cycle. Primary end points were safety and determination of the MTD. ORR was assessed by IMWG 2006. Exploratory biomarker analyses included analysis of PD-L1 and PD-L2 on $CD38^+CD138^+$ cells in BM aspirate samples obtained at screening, or before the first dose of study drug. Absolute and/or relative numbers of circulating lymphocytes (by flow cytometry [FC]) and gene expression profile (GEP) (by Nanostring) were evaluated in predose; cycle 1, day 1 (C1D1); and cycle 2, day 1 (C2D1) blood samples.
Results: MTD was determined as pembro 200 mg IV Q2W plus len 25 mg and dex 40 mg. Median (range) age was 61 years (46-77); median (range) number of prior lines of therapy was 4 (1-10); 38 (75%) patients were len-refractory, and 27 (53%) were double refractory. Most common grade ≥3 treatment-related AEs (TRAEs) were neutropenia (33%), thrombocytopenia (18%), and anemia (12%). 2 patients (4%) died because of TRAEs (hepatic failure, ischemic stroke). Immune-related AEs occurred in 5 (10%) patients. No pneumonitis was reported. ORR in the efficacy population was 20/40 (50%) (1 sCR, 5 VGPR, 14 PR); 1 patient had progressive disease. ORR was 38% (11/29) and 33% (6/18) for len- and double-refractory patients, respectively. The disease control rate (sCR+CR+ VGPR+PR+SD) was 39/40 (98%) in the efficacy population and 28/29 (97%) in the len-refractory population. 35/40 (88%) patients had a reduction in M protein or free light chains. In 16/32 patients with FC-evaluable BM aspirate with >100 $CD38^+CD138^+$ cells, all were $PD\text{-}L1^+$, while PD-L2 expression was variable. At C2D1, proportion of circulating $HLA\text{-}DR^+$, central ($CD45RO^+CCR7^-$), and effector memory ($CD45O^+CCR7^+$) $CD8^+$ T cells significantly increased and naive ($CD45RA^+$) $CD8^+$ T cells significantly decreased; all with multiplicity adjusted *P* values ≤0.01.
Summary/Conclusions: The combination of pembro, len, and low-dose dex has an acceptable safety profile and antitumor activity in patients with heavily pretreated RRMM, including len-refractory and double-refractory patients. PD-L1 was expressed in all patients evaluated by FC, whereas PD-L2 expression was variable. Pembro plus len and low-dose dex induced immune activation in the periphery and a phenotypic shift in effector $CD8^+$ T cells among the circulating T-cell pool in blood.

Old and new drugs in MPN

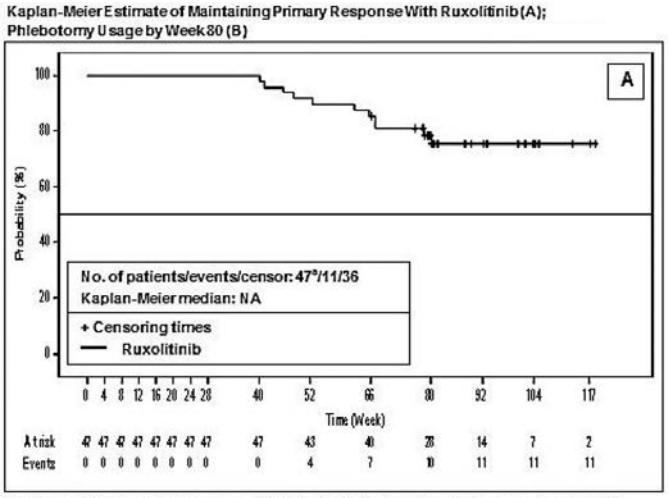
Background: Polycythemia vera (PV) is characterized by hyperproliferation of erythroid/myeloid/megakaryocytic components in the bone marrow, cardiovascular complications, and high symptom burden. Treatment (Tx) in patients (pts) with PV is focused on maintaining hematocrit (HCT) level <45%. RESPONSE-2 study evaluated the efficacy and safety of ruxolitinib (RUX) *vs* best available therapy (BAT) in hydroxyurea (HU)-resistant/intolerant pts with PV ≥18 years without splenomegaly and with phlebotomy [PBT] requirement to control HCT. At week (wk) 28 (primary analysis), HCT control was reported in 46/74 pts in the RUX arm *vs* 14/75 pts in the BAT arm.
Aims: This preplanned analysis of RESPONSE-2 evaluated the durability of efficacy and safety of RUX *vs* BAT, after all pts reached 80 wk into the study or discontinued the study.
Methods: Pts were randomized 1:1 to RUX 10 mg twice daily or BAT. Primary end point was the proportion of pts who achieved HCT control at wk 28 (absence of PBT eligibility [HCT >45%, ie, ≥3 percentage points from baseline, or HCT >48%] from wk 8 to 28, with ≤1 PBT eligibility from wk 0 to 8). Key secondary end point was the proportion of pts who achieved complete hematologic remission at wk 28 (CHR: HCT <45%, WBC ≤10 x 10^9/L, platelet count ≤400 x 10^9/L). Durability of HCT, CHR, and safety was evaluated at wk 80 (data cutoff, September 26, 2016). Additional end points included assessment of patient-reported outcomes (MPN-SAF TSS) and change in *JAK2V617F* allele burden over time. BAT pts could cross over to RUX from wk 28.
Results: Baseline demographics were comparable among RUX (N=74) and BAT (N=75) arms. When last pt reached wk 80 time point, 69 pts randomized to RUX were still receiving Tx; while 5 pts discontinued Tx (adverse events [AEs]=3 pts, physician's decision/pt withdrew consent=1 pt, each). In BAT arm, 58 pts crossed over to RUX (crossover data to be included in presentation) with remaining pts either ongoing follow-up (f/u [n=5]) or having discontinued Tx (completed f/u per protocol, n=7; death, n=1; other reasons, n=4). Median exposure was 93.6 wk in RUX *vs* 28.4 wk in the BAT arm. At wk 80, durable HCT control was achieved in 35 pts (47%) in RUX *vs* 2 pts (3%) in BAT arm. Of those who achieved a HCT response at wk 28, Kaplan-Meier estimate of maintaining response up to wk 80 was 78.37% in the RUX arm. Durable CHR was achieved in 18 pts (24%) in RUX *vs* 2 pts (3%) in the BAT arm. Total number of PBT was higher in the BAT arm *vs* RUX arm (Figure 1). At wk 80, 45% of pts randomized to RUX continued to achieve a ≥50% of reduction in the MPN-SAF TSS. At wk 80, mean percentage change from baseline in *JAK2V617F* allele burden was −9.7% in the RUX (n=65) *vs* +0.3% in the BAT arm (n=3). AEs observed were consistent with those generally reported with RUX (primarily low grade [G]). Most common AEs (all G, exposure-adjusted rate per 100 pt-years) were anemia (14.3), weight increase (10.6), arthralgia (9.1), and pruritus (9.1) in the RUX arm *vs* pruritus (37.5), headache (16.9), and thrombocytopenia (15.0) in the BAT arm. Rate of thromboembolic events (Standardized MedDRA Query, exposure-adjusted) was RUX (1.5) *vs* BAT arm (1.9). No pt in the RUX arm had disease progression *vs* 2 pts in the BAT arm. No deaths were reported in the RUX arm *vs* 3 pts in the BAT arm (septic shock/disease progression/study indication=1 pt, each).
Summary/Conclusions: RUX provided durable HCT control, durable CHR, reduction in PBT requirement, improved symptom burden, and was generally well tolerated with >90% of pts still receiving Tx at wk 80. RUX Tx provided a modest reduction in allele burden over time. Findings from both RESPONSE studies suggest that RUX should be considered as a standard of care for second-line Tx in this inadequately controlled pt population with PV.



[a]During week 80 data review, 1 more ruxolitinib-treated patient was found to be responding at week 28 (compared to original analysis done with week 28 data cut); updating the number of primary responders to 47.

Phlebotomy usage by week 80 (B)		
Phlebotomy frequency	Ruxolitinib, N=74, n (%)	BAT, N=75, n (%)
0	54 (72.9)	27 (36.0)
1-2	15 (20.3)	29 (38.7)
3-4	5 (6.8)	16 (21.3)
>4	0 (0)	3 (4.0)
Total number of phlebotomies	36	106

PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB *VERSUS* RUXOLITINIB IN JAK INHIBITOR NAIVE PATIENTS WITH MYELOFIBROSIS: RESULTS OF THE SIMPLIFY-1 STUDY

J.R. Gotlib[1,*], J.-J. Kiladjian[2], J.V. Catalano[3], T. Devos[4], M. Egyed[5], A. Hellman[6], D.P. McLornan[7], K. Shimoda[8], E.F. Winton[9], W. Deng[10], R.L. Dubowy[10], J.D. Maltzman[10], F. Cervantes[11], R.A. Mesa[12]
[1]Stanford University Medical Center, Stanford, United States, [2]Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, [3]Monash University, Melbourne, Australia, [4]University Hospitals Leuven, Leuven, Belgium, [5]Kaposi Mor Teaching Hospital, Kaposvar, Hungary, [6]Medical University of Gdańsk, Gdańsk, Poland, [7]Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom, [8]University of Miyazaki, Miyazaki, Japan, [9]Emory University School of Medicine, Atlanta, [10]Gilead Sciences, Inc., Foster City, United States, [11]Hospital Clinic, University of Barcelona, Barcelona, Spain, [12]Mayo Clinic Cancer Center, Scottsdale, United States

Background: Momelotinib (MMB), an investigational oral JAK inhibitor (JAKi), has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis (MF).
Aims: To test the non-inferiority of MMB *vs* ruxolitinib (RUX) in splenic volume reduction and symptom amelioration, and superiority in transfusion requirement, in JAKi naïve patients with primary myelofibrosis, and post-polycythemia vera or post-essential thrombocythemia myelofibrosis.
Methods: Eligibility included primary myelofibrosis or post-polycythemia vera/essential thrombocythemia myelofibrosis; International Prognostic Scoring System (IPSS) high risk, intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; palpable spleen ≥5cm; platelets ≥50 K/µl; no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependency and platelets (<100K, 100K-200K, and >200K/µl). Patients were randomized 1:1 to 24 weeks of MMB 200 mg qd+RUX placebo or RUX 20 mg bid (or modified per label)+MMB placebo, after which all patients could receive open label MMB. Assessments: spleen volume by MRI, and patient reported symptoms using a daily eDiary of modified MPN-SAF Total Symptom Score (TSS). The primary endpoint was splenic response rate (SRR; ≥35% reduction in volume from baseline) at 24 weeks. Secondary endpoints, evaluated sequentially at 24 weeks, were rates of TSS response (≥50% reduction from baseline), RBC transfusion independence and RBC transfusion dependence, and rate of RBC transfusion.
Results: 175 of 215 (81%) and 201 of 217 (93%) patients randomized to MMB and RUX, respectively, completed the 24 week double blind phase. Efficacy results are shown in the Table 1. The most common Grade ≥3 adverse events in the double blind phase with MMB were thrombocytopenia (7%) and anemia (6%), and with RUX were anemia (23%), thrombocytopenia (5%) and neutropenia (5%). Grade ≥3 infections occurred in 7% of MMB and 3% of RUX patients. Treatment emergent peripheral neuropathy occurred in 22 (10%) of MMB (all Grade ≤2) and 10 (5%) of RUX (9 Grade ≤2, 1 Grade 3) patients in the double blind phase, none discontinuing study drug for this problem. Overall, adverse events led to study drug discontinuation in 13% of MMB and 6% of RUX patients in double blind phase.

Table 1.

Endpoints	MMB	RUX	*p*-value
Spleen response rate, %	26.5	29.0	0.011[a]
TSS response rate, %	28.4	42.2	0.98[a]
Transfusion independence rate, %	66.5	49.3	<0.001[b]
Transfusion dependence rate, %	30.2	40.1	0.019[b]
Transfusion rate (units/month), median	0.0	0.4	<0.001[b]

[a]*Test for non-inferiority;* [b]*Test for superiority, all values nominally significant.*

Summary/Conclusions: In patients with JAKi naive myelofibrosis, 24 weeks of momelotinib is non-inferior to ruxolitinib for spleen response but not for symptom response. Momelotinib treatment is associated with a reduced transfusion requirement. NCT01969838

S786

PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB *VERSUS* BEST AVAILABLE THERAPY IN PATIENTS WITH MYELOFIBROSIS PREVIOUSLY TREATED WITH RUXOLITINIB: RESULTS OF THE SIMPLIFY-2 STUDY

S. Verstovsek[1], A.M. Vannucchi[2], U. Platzbecker[3], F. Cervantes[4], V. Gupta[5], D. Lavie[6], F. Passamonti[7], E.F. Winton[8], H. Dong[9], J. Kawashima[9], J.D. Maltzman[9], J.-J. Kiladjian[10], C.N. Harrison[11,*]
[1]University of Texas MD Anderson Cancer Center, Houston, United States, [2]University of Florence, Florence, Italy, [3]Medizinische Fakultät Carl Gustav Carus, Technische Universität, Dresden, Germany, [4]Hospital Clinic, University of Barcelona, Barcelona, Spain, [5]Princess Margaret Cancer Centre, University of Toronto, Toronto, Canada, [6]Hadassah-Hebrew University Medical Center, Jerusalem, Israel, [7]University of Insubria, Varese, Italy, [8]Emory University School of Medicine, Atlanta, [9]Gilead Sciences, Inc., Foster City, United States, [10]Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, [11]Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom

Background: Momelotinib (MMB), an investigational oral JAK inhibitor, has been shown in early trials to reduce spleen volume, improve disease associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis.
Aims: Test the superiority of MMB *versus* best available therapy (BAT) in splenic volume reduction, symptom amelioration, and transfusion requirement at 24 weeks in patients with primary myelofibrosis (PMF), post-polycythemia vera or post-essential thrombocythemia myelofibrosis (Post-PV/ET MF) who were previously treated with ruxolitinib.
Methods: Eligibility included PMF or post-PV/ET MF; Dynamic International Prognostic Scoring System (DIPSS) high risk or intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; currently or previously treated with ruxolitinib for at least 28 days who either required transfusions or dose reduction to <20 mg BID with at least one of Grade ≥3 thrombocytopenia, anemia, or bleed; palpable spleen ≥5cm; and no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependency and baseline TSS (modified MPN-SAF Total Symptom Score) <18 or ≥18. Patients were randomized 2:1 to 24 weeks of open-label MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary for TSS. Primary endpoint was splenic response rate at 24 weeks (SRR24; ≥35% reduction in volume from baseline). Secondary endpoints, evaluated sequentially, were rates of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion, RBC transfusion independence (TI) and RBC transfusion dependence (TD).
Results: 73 of 104 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for 88% of patients included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), asthenia (19%), nausea (19%), and cough (17%), and in BAT patients, asthenia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (13%) and thrombocytopenia (7%), and in BAT patients, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

Table 1.

Endpoints	MMB	BAT	*p*-value
SRR, %	6.7	5.8	0.90
TSS RR, %	26.2	5.9	<0.001[a]
Transfusion rate (units/month), median	0.5	1.2	0.39
TI rate, %	43.3	21.2	0.001[a]
TD rate, %	50.0	63.5	0.10

[a]*p-values nominally significant.*

Summary/Conclusions: In previously ruxolitinib-treated patients with myelofibrosis, 24 weeks of momelotinib was not superior to best available therapy for splenic response, but significantly better in improving disease related symptoms and transfusion independence. *NCT02101268.*

S787

MOLECULAR RESPONSE TO HYDROXYUREA AND ROPEGINTERFERON ALFA-2B IN THE PROUD-PV RANDOMIZED PHASE 3 TRIAL

J.-J. Kiladjian[1,2,3,*], B. Cassinat[2,4], J. Soret-Dulphy[1], E. Verger[4], L. Roy[5], J. Rey[6], N. Maslah[4], B. Grohmann-Izay[7], C. Klade[7], H. Gisslinger[8]
[1]Clinical Investigations Center, Hopital Saint-Louis, [2]INSERM UMRS-1131, [3]Paris Diderot University, [4]Hopital Saint-Louis, Paris, [5]Hopital Henri Mondor, Créteil, [6]Institut Paoli Calmettes, Marseille, [7]AOP Orphan Pharmaceuticals AG, [8]Medical University of Vienna, Vienna, France

Background: Interferon alfa (IFNa) has been successfully used to treat myeloproliferative neoplasms (MPN) for many years and several phase 2 studies have independently shown high rates of hematological and molecular responses assessed by the quantification of mutant JAK2 allele burden (%JAK2V617F) in peripheral blood. However, direct *in vivo* studies investigating the impact of IFNa treatment on proliferation of bone marrow (BM) normal and malignant hematopoietic progenitors are lacking.
Aims: We took advantage of the randomized controlled phase III trial (PROUD-PV) comparing the novel, long-acting Ropeginterferon alfa-2b (AOP2014) with hydroxyurea (HU) in polycythemia vera (PV) patients (pts) to assess correlation between evolution of %JAK2V617F in peripheral blood and the impact of therapy on malignant clones by functional assays testing mutant BM hematopoietic progenitors in the French study population.
Methods: Randomized, controlled, multicenter phase 3 trial comparing efficacy, safety and tolerability of hydroxyurea and Ropeginterferon Alfa-2b in PV pts (NCT01949805). The primary endpoint was non-inferiority of AOP2014 *vs* HU at 12 months (mos) of therapy in terms of complete hematological response (CHR) according to ELN criteria and normal spleen size. As important secondary endpoint the effect of treatment on %JAK2V617F was assessed as rate of complete and partial molecular response (C/PMR) according to modified ELN criteria. In the group of pts enrolled in France, we could study BM progenitors clonogenic potential by cultures with or without Erythropoietin (EPO) at baseline and after 12 months of therapy. The presence of colonies without EPO, namely Endogenous Erythroid Colonies (EECs) is a hallmark of PV. After 14 days, erythroid colonies were enumerated and picked for molecular analyses.
Results: A total of 257 pts were randomized in 13 European countries including 13 pts in France. Non-inferiority of AOP2014 *versus* HU regarding CHR could be demonstrated in the whole study population (43.1 *vs* 45.6%). In the subgroup of French pts (54% males, mean age 55 years) CHR at 12 mos was 40% in pts receiving AOP2014 (n=5) and and 50%, in those receiving HU (n=8). %JAK2V617F at baseline in the AOP2014 and HU arms were 39.4% and 46.5%, respectively, reduced to 29.1% and 25.8% after 6 mos, and 13.8% and 33.2% at 12 mos. No complete MR was achieved at 12 mos, but PMR was observed in 40% and 25% of pts in AOP2014 and HU arms (p= ns), respectively. BM progenitors could be studied in 10/13 French pts, 3 treated with AOP2014 and 7 with HU. AOP2014 treatment induced an important decrease of the proportion of EEC (median decrease 64%) between samples collected at baseline and after 12 months of therapy compared to HU (median decrease 25%). In addition, clonal architecture studies showed that the % of JAK2V617F mutant colonies before and after treatment profoundly decreased in all AOP2014-treated pts (mean ratio of mutant *vs* wild type JAK2 colonies decreased from 96% at baseline to 46% at 12 mos). Among HU-treated pts, only 1 experienced a decrease in the % of mutated colonies while mean ratio of mutant *vs* wild type JAK2 colonies didn't significantly decrease (from 87% at baseline to 79% after 12 mos).
Summary/Conclusions: In this phase 3 trial comparing Ropeginterferon alfa-2b *versus* HU, we found a different impact of both drugs on hematopoietic cells. Although both treatment induced a decrease of JAK2 mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2 mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strikingly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.

S788

POOLED SURVIVAL ANALYSIS OF MIDOSTAURIN CLINICAL STUDY DATA (D2201+A2213) IN PATIENTS WITH ADVANCED SYSTEMIC MASTOCYTOSIS COMPARED WITH HISTORICAL CONTROLS

A. Reiter[1,*], H.C. Kluin-Nelemans[2], T. George[3], C. Akin[4], D.J. DeAngelo[5], O. Hermine[6], F. Awan[7], E. Hexner[8], M. Mauro[9], J. Schwaab[1], M. Jawhar[1], D. Sternberg[10], N. Berkowitz[10], J. Niolat[11], A. Huntsman Labed[12], K. Hartmann[13], H.-P. Horny[14], P. Valent[15], J. Gotlib[16]
[1]University Medical Centre Mannheim, Mannheim, Germany, [2]University Medical Center Groningen, Groningen, Netherlands, [3]University of New Mexico, Albuquerque, [4]Brigham and Women's Hospital, [5]Dana-Farber Cancer Institute, Boston, United States, [6]University of Paris Descartes, Imagine Institute, Paris, France, [7]The Ohio State University Comprehensive Cancer Center, Columbus, [8]University of Pennsylvania, Philadelphia, [9]Memorial Sloan Kettering Cancer Center, New York, [10]Novartis Pharmaceuticals Corporation, East Hanover, United States, [11]Novartis Pharma SAS, Rueil-Malmaison, France, [12]Novartis Pharma AG, Basel, Switzerland, [13]University of Cologne, University of Luebeck, Cologne, [14]Ludwig Maximilians University Munich, Munich, Germany, [15]Medical University of Vienna, Vienna, Austria, [16]Stanford University School of Medicine, Stanford, United States

Background: AdvSM (ie, aggressive SM [ASM], SM with an associated hematologic neoplasm [SM-AHN], and mast cell leukemia [MCL]) comprises rare hematologic neoplasms with a poor prognosis. KIT D816V mutations occur in a majority of patients with advSM. Midostaurin is a multitargeted kinase inhibitor that blocks wild-type and D816V-mutated KIT. Two single-arm phase 2 studies (D2201+A2213) evaluated the safety and efficacy of midostaurin in advSM. Overall, 60% and 69% of patients in D2201 and A2213, respectively, achieved the primary endpoint of partial or complete normalization of SM-related organ damage.
Aims: We compared pooled data from these studies with data from a patient registry to determine the effects of midostaurin on overall survival (OS).
Methods: Data from the midostaurin studies, in which patients received midostaurin 100 mg twice daily until progression or toxicity, were pooled. Historical control data were obtained from a contemporary patient registry based at University Medical Centre Mannheim, Germany. Although the primary analysis did not include matching for patient selection, subgroup analyses, and multivariate analyses were performed to assess whether baseline patient characteristics affected OS and estimated HR. Propensity scoring was used for supportive analyses to match the patients in the registry. Patients were evaluated for OS based on time from diagnosis to death; patients in the pooled analysis with known dates of diagnosis were included in the primary analysis. A sensitivity analysis to compensate for potential bias in patient selection was conducted using the start date of last treatment to death.
Results: The primary analysis of OS in patients with advSM included 89 patients from the midostaurin pooled analysis for whom the date of diagnosis was available (77% of the entire pooled cohort) and all 46 patients from the German registry who had not been treated with midostaurin. SM subtypes among patients from the pooled analysis and registry were similar; 66% of patients in the pooled cohort and 63% in the registry had an AHN (Table 1).*KIT* D816 mutations were present in 82% of patients in the pooled analysis and 96% in the registry. More patients in the registry (67%) *vs* the pooled analysis (42%) were aged >65 y. Median follow-up (time from diagnosis to data cutoff for the analyses) was similar for the 2 patient groups: registry, 54.9 (range, 1.9-150.4) mo and midostaurin, 53.6 (range, 31.6-215) mo. Patients in the midostaurin pooled analysis had a clinically relevant improvement in OS *vs* historical controls (HR=0.62 [95% CI, 0.39-0.98]; P=.0204; Figure 1). Median OS was 42.6 (95% CI, 31.0-53.9) mo in the pooled analysis *vs* 24.0 (95% CI, 13.0-39.5) mo in the registry. Multivariate Cox regression analysis after adjusting for covariates was consistent with the primary analysis: HR=0.51 (95% CI, 0.30-0.88); P=.0147. Data using propensity score for matched pairs (n=44) were also consistent (HR=0.381 [95% CI, 0.169-0.960]; P=.101). Subgroup analyses of OS showed HR in favor of midostaurin for all subgroups analyzed (age [≤65 y *vs* >65 y], *KIT* D816V status, number of prior therapies [≤1 *vs* >1], and SM subtype) except MCL. Subgroup analysis data should be interpreted with caution due to the small patient numbers in the German registry. Sensitivity analysis of OS from date last treatment received (pooled analysis, n=115; registry, n=42) was consistent with the main analyses (HR from the multivariate analysis=0.38 [95% CI, 0.22-0.65]; P=.0004).

Table 1.

Patient characteristics

	Pooled Analysis: Midostaurin-Treated Patients (N=89)	Registry (N=46)
Age at diagnosis, n (%)		
≤65 y	52 (58)	15 (33)
>65 y	37 (42)	31 (67)
KIT D816 mutation status, n (%)		
Not mutated	15 (17)	2 (4)
Mutated	73 (82)[a]	44 (96)[b]
Unknown	1 (1)	0
SM subtype, n (%)		
ASM	16 (18)	12 (26)
SM-AHN	59 (66)	29 (63)
MCL	14 (16)	5 (11)
Median time from diagnosis to start of last therapy (interquartile range), mo	2.2 (0.5-7.8)	5.5 (0.8-21.0)
Median no. of prior therapies (range)	2 (1-5)	2 (0-5)
No. of prior therapies, n (%)		
0	0	4 (9)
1-2	68 (76)	27 (59)
≥3	21 (24)	15 (33)

[a] Includes 67 patients with D816V mutations, 1 with D816Y, and 5 with missing/undetermined D816 mutations.
[b] All 44 patients had D816V mutations.

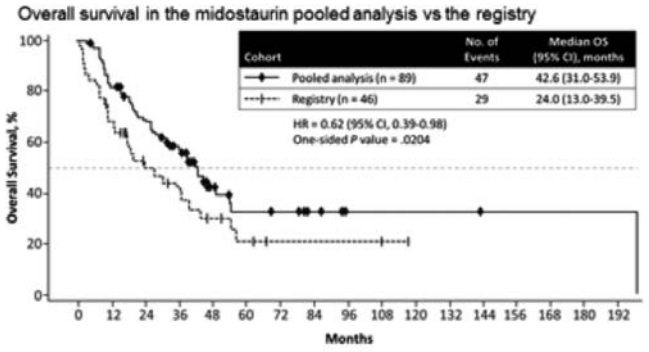

Figure 1.

Summary/Conclusions: Midostaurin was associated with a 38% lower risk of death *vs* historical controls. Benefit was generally consistent across key subgroups.

Childhood and more intensive treatment of AML

S789

LOW-DOSE CYTARABINE TREATMENT IN CHILDREN WITH DOWN SYNDROME AND TRANSIENT MYELOPROLIFERATIVE DISORDER TO PREVENT ML-DS: AML-BFM TMD PREVENTION 2007 STUDY

M. Flasinski[1,*], K. Scheibke[1], M. Zimmermann[1], K. Reinhardt[2], D. Reinhardt[2], C. von Neuhoff[2], J.-H. Klusmann[1]
[1]Department of Paediatric Haematology and Oncology, Hannover Medical School, Hannover, [2]Pediatric Oncology and Hematology, Pediatrics III, University Hospital of Essen, Essen, Germany

Background: Approximately 10% of the children with Down syndrome are diagnosed with transient myeloproliferative disorder (TMD) within the first days of life. Previous studies have shown that TMD patients face an around 20% risk of early death and a 20% to 30% risk to develop myeloid leukemia during the first 4 years of life (ML-DS).
Aims: The aim of the AML-BFM TMD Prevention 2007 trial was to analyze the outcome of patients diagnosed with TMD and to evaluate whether the application of a low-dose cytarabin treatment can prevent the progression to ML-DS.
Methods: The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabin treatment (1.5 mg/kg i.v./s.c. daily) for one week respectively if they met the following criteria: TMD-related symptoms (*e.g.* hyperleucocytosis, hepatopathy) at diagnosis, MRD-positivity (FACS≥10^{-3} or qPCR≥10^{-4}) eight weeks after diagnosis. Patients could receive cytarabin-treatment up to three weeks in case of failure to respond to the cytarabin-treatment (morphologic detection of blasts between week four and eight after diagnosis and/or MRD-positivity after treatment in week ten after diagnosis).
Results: Here we report a cohort of 108 patients (male: 60, female:48) diagnosed with TMD. The median age at diagnosis was 4 days. As common in children with Down syndrome, many of the patients presented with comorbidities (cardiac defects: 68%, other malformations: 15%); 36% were delivered preterm. 45 patients received low-dose cytarabin treatment, 57 patients did not receive this treatment. Overall, patients in this trial do not show a significantly better event-free survival (EFS; 72±4% *vs* 63±4%, p=0.15) and overall survival (OS; 91±3% *vs* 85±3%, p=0.15) than the historic control group (n=146). The cumulative incidence (CI) of death was lower, (8±3% *vs* 15±3%) albeit not significantly (p=0.09). The CI of ML-DS was also similar (19±4% *vs* 22±4%, p=0.88). Patients that presented with TMD-related clinical symptoms (n=43; symptoms: hyperleucocytosis [WBC>100,000], hepatopathy, ascites, hydrops fetalis) had a tendency for a better EFS (59±8% *vs* 44±8%, p=0.097), OS (80±6% *vs* 67±7% p=0.10) and CI of death (20±7% *vs* 33±7%, p=0.10) than patients with those symptoms in the historic control group (n=45). For the progression to ML-DS there is no significant difference between the two groups (21±7% *vs* 23%±7%, p=0.91). For patients that do not show any of the TMD-related symptoms (n=59), no significant differences were observed regarding EFS (81±5% *vs* 71±5%, p=0.27), OS (98% *vs* 93±3%, p=0.16) and CI of ML-DS (19±6% *vs* 22±4%, p=0.95) compared to patients without these symptoms in the historic control (n=101).
Summary/Conclusions: The consequent treatment with low-dose cytarabine of symptomatic patients results in a trend towards reduced CI of death as compared to the historic control. However, progression to ML-DS remained unchanged suggesting that the treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabine to reduce disease-related mortality.

Background: AML is a heterogeneous disease based on genetic characteristics with impact on prognosis. So, it becomes necessary to treat patients according to risk-adapted therapies.
Aims: To analyze the results of intensive induction and post-remission treatment in 868 patients with the novo AML enrolled into the CETLAM-03 trial between 2003 and 2012 with a prolonged follow-up (results reported at 10 years).
Methods: Patients received 1 or 2 induction chemotherapy courses of IDICE-G (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with G-CSF) followed by mitoxantrone and IDC as consolidation therapy. Further treatment was assigned according to the CETLAM risk groups as follows: Favorable risk (FR) defined as favorable cytogenetics according to MRC: autologous stem cell transplantation (ASCT) if leukocyte index [LI=leucocytes x (BM blasts/100)] ≥20 or high dose cytarabine (HDAC) (one course) if LI <20. Intermediate risk (IR), defined as patients in CR after a single induction course, <50x10E9/l white blood cells at diagnosis, normal karyotype and absence of FLT3 internal tandem duplication (FIT3-ITDwt) and no MLL rearrangement: ASCT . Adverse risk (AR), patients not included in FP or IP: ASCT or allogeneic stem cell transplantation (allo-SCT) depending on donor availability (HLA-identical sibling or unrelated donor if high risk of relapse).
Results: There were enrolled 868 patients. Median age was 53 years-old (16-70). According to MRC cytogenetics, available in 802 patients, 99 belonged to the favorable (12%), 581 (73%) to the intermediate and 122 (15%) to the adverse groups. 66 patients with no metaphases. FLT3-ITD was present in 128 patients with normal karyotype (36%). Four patients died before treatment and 864 patients received induction therapy. 77% of patients achieved a CR (88% with a single course), 11% were refractory and 12% died during induction. CR rate was 92% in CBF leukemia, 91% in NPM1 mutation without FLT3-ITD, 77% in intermediate cytogenetic and no mutations, 74% if FLT3-ITD, 70% in adverse cytogenetics and 62% if monosomal karyotype was present (p<0.001). The multivariate analysis showed that mutational status (adverse cytogenetics, FLT3-ITD and absence of NPM1 mutation) had an adverse impact on CR achievement. Overall survival (OS), event free survival (EFS) and cumulative incidence of relapse (CIR) of the whole series at 10 years were: 36±2%, 29±2% and 44±5% respectively. Post-remission results of OS, EFS and CIR according to the different CETLAM risk groups at 10 years follow up were: FR (n=85, 14%): 85±4%, 70±6% and 22±1%; IR (n=99, 17%): 64±6%, 51±5% and 47±2%; AR (n=417, 69%): 41±3%, 33±3% and 52±16% respectively. In FR there were no differences in OS, EFS and CIR depending if intention to treat was HDAC or ASCT. In AR statistical differences were observed at 10 years in EFS and CIR when comparing ASCT *vs* allo-SCT (27±4% *vs* 39±4%, p=0.026 and 66±6% *vs* 39±1%, p<0.001). In IR intention to treat was ASCT, but in 21% mobilization failed and most of them received HDAC. Forty-nine patients received an ASCT and 21 relapsed, 9 of them were rescued with an allo-SCT.
Summary/Conclusions: In this large cooperative experience CR rate was above 75%, in most cases after a single course. In patients with favorable MRC cytogenetics, the adverse impact of high LI observed in our previous protocol was abrogated with autologous transplantation. In IR group, a remarkable proportion of patients allocated to ASCT had mobilization failure. In HR group, allo-SCT improves the outcome compared to ASCT. In our experience, molecular characterization and MRD studies are helpful to decide post-remission therapy.

S791

MOLECULAR PREDICTORS OF RESPONSE TO AZACITIDINE THERAPY: THE RESULTS OF THE UK TRIALS ACCELERATION PROGRAMME RAVVA STUDY

C. Craddock[1,*], L. Quek[2], A. Houlton[3], P. Ferguson[4], E. Gbandi[3], C. Roberts[5], M. Metzner[2], K. Wheatley [6], S. Siddique[6], S. Pillai[7], M. Dennis[8], J. Cavenagh[9], P. Vyas[10]
[1]Centre for Clinical Haematology, University of Birmingham, University of Birmingham, Birmingham, [2]Haematology, Weatherall Institute of Molecular Medicine, Oxford, [3]Cancer Research UK Clinical Trials Unit, University of Birmingham, [4]Haematology, Centre for Clinical Haematology, Queen Elizabeth Hospital, Birmingham, [5]Haematology, Oxford, Oxford, [6]CRCTU, University of Birmingham, Birmingham, [7]Haematology, University Hospital of North Staffordshrire, Stoke on Trent, [8]Haematology, The Christie NHS Foundation Trust, Manchester, [9]Department of Haemato-Oncology, St Bartholomews Hospital, London, [10]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom

Background: Azacitidine (AZA) represents an important therapeutic advance in patients with acute myeloid leukaemia (AML) and high risk myelodysplasia (MDS) ineligible for intensive chemotherapy. However disease progression appears inevitable and a number of strategies aimed at improving outcome, including co-administration of histone deacetylase inhibitors such as vorinostat (VOR), have been proposed. Leukaemic stem/progenitor cells (LSC) have been postulated to represent a reservoir of resistant disease but the impact of AZA based therapy on LSC numbers has not been studied. An additional factor limiting the rational use of AZA based therapy in AML and MDS is imprecision in the identification of patients likely to achieve a significant clinical benefit and molecular predictors of outcome would improve the rational utilisation of thsi important new agent.
Aims: We wished to study the impact of AZA based therapy on LSC numbers aswell as identify molecular predictors of outcome in patients treated on the recently completed UK Trials Acceleration Programme RAVVA randomised Phase II trial which compared AZA monotherapy with AZA/VOR combination therapy.
Methods: The RAVVA trial randomized 259 adults with AML (n=217) and MDS (n=42) to receive AZA monotherapy (AZA (75 mg/m^2) x 7 days every 28 days) or AZA combined with VOR (300 mg bd days 3-9) po for a minimum of 6 cycles. Next generation sequencing was performed on 42 genes commonly mutated in AML and MDS in 250 patients treated on the RAVVA trial and correlated with response. Separately serial immunophenotypic quantitation of leukaemic stem/progenitor cells (LSC) was performed in 44 patients.
Results: Co-administration of VOR did not increase overall survival (OS) (1 year OS AZA 43% *versus* 41% p=0.32) as previously reported (Blood 2016 Absract No 1065). The mean number of mutations per patient in the 250 genotyped patients was 3.4. The presence of mutations in CDKN2A (p=0.0001), IDH1 (p=0.004) and TP53 (p=0.003), NPM1 (p=0.037) and FLT3-ITD (p=0.04) were associated with reduced OS in univariate analysis. In multivariate analysis adjusted for all clinical variables mutations in CDKN2A, IDH1 and TP53 remained predictive of decreased OS. No mutations were associated with improved OS. The presence of ASXL1 (p=0.035) and ETV6 (p=0.033) mutations were found to be associated with a reduced duration of response. AZA based therapy had no significant impact on LSC numbers in patients who failed to achieve a CR. LSC numbers were reduced but not eradicated in patients achieving a CR and observed to expand at relapse.
Summary/Conclusions: In this, the largest such study reported to date, the demonstration that mutations in CDKN2A, IDH1 and TP53 are associated with a decreased OS in patients treated with AZA not only can inform patient risk stratification but also provides insights into the mechanism of action of AZA. Specifically, the observation that mutations in the cell cycle regulator CDKN2A was associated with a markedly decreased overall survival is consistent with the hypothesis that induction of cell cycle arrest represents at least one of the mechanisms by which AZA exerts an anti-tumour activity. Furthermore our data identify serial quantitation of LSC populations as a potentially important biomarker of response to AZA based therapies which may assist in the evaluation of novel treatment combinations.

S792

SORAFENIB MAINTENANCE IN FLT3-ITD MUTATED ACUTE MYELOID LEUKEMIA AFTER ALLOGENEIC STEM CELL TRANSPLANT

S. Ahmed[1], R. Saliba[1], G. Rondon[1], A. Alousi[1], Q. Bashir[1], S. Ciurea[1], G. Al-Atrash[1], K. Patel[2], A. Olson[1], D. Marin[1], K. Rezvani[1], P. Kebriaei[1], U. Popat[1], E. Shpall[1], R. Champlin[1], B. Oran[1,*]
[1]Stem cell transplant and cellular therapy, [2]Hematopathology, University of Texas, MD Anderson Cancer Center, Houston, United States

Background: The fms-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD) mutation is a genetic alteration found in approximately 30% of patients with acute myeloid leukemia (AML). Although patients with FLT3-ITD AML achieve remission rates similar to those with FLT3 wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse comparatively with poor prognosis post relapse. Sorafenib(SFB) is a TKI with activity against RAF, VEGF and FLT3-ITD and its use as maintenance therapy after allogeneic SCT has been shown as a promising approach to decrease relapse. Several studies report that SFB maintenance post SCT provides durable complete responses; however, there are also descriptions of sorafenib post SCT triggering acute GVHD, cytopenias, rash and diarrhea.
Aims: To assess the outcomes, including progression free survival (PFS) and overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB maintenance after allogeneic SCT.
Methods: We analyzed adult patients (age≥18) with a diagnosis of FLT3-ITD mutated AML who received an allogeneic SCT between 1/1/2010 and 10/28/16 at our institution. Using a case control analysis and matching patients who received maintenance SFB (maintenance group) with control patients, FLT3-ITD mutated AML who did not receive maintenance post SCT(control group); we matched each case to two control patients accounting for disease status, type of conditioning, donor type, cytogenetic risk factors and age. To be considered as maintenance, SFB had to be started within 101 days of the SCT. To reduce bias from disease risks and transplant-related mortality (TRM), all patients were required to be in complete remission (CR) at study entry - defined as the date of SFB initiation for cases and the same time point after SCT for their matched controls without maintenance. Actuarial OS and PFS were estimated from study entry using Kaplan-Meier method. OS and PFS were compared between cases and controls using log rank test and cox proportional hazards regression analysis. Patient-, transplant- and disease characteristics were compared between cases and controls using chi square and Fisher exact tests.
Results: Among the 214 AML patients with FLT3-ITD mutation that underwent SCT during study period, we identified 13 cases (maintenance) and 26 controls (no maintenance). Median follow-up of survivors were 12 months and 30 months for maintenance and control group respectively. Disease and transplant

characteristics were comparable between groups as presented in Figure 1. Patients were classified by the European Leukemia Net (ELN) classification and 23% in both groups were categorized as adverse risk while 77% were intermediate risk. All patients received myeloablative conditioning and diseases status at SCT was first/second complete remission (CR1/2) with or without count recovery (Cri/p) in 69% while it was active disease in 31%. PFS at 24 months post SCT was 82% in the maintenance and 45% in control group HR 0.3; 95% CI (0.1-1.3) p=0.1. Overall survival at 24 months was also higher in SFB cases as 100% compared with 60% in control group p=0.035. Only, 2 patients relapsed post SCT on SFB maintenance, one with new TP53 mutation at relapse, and other received only <30 days of SFB. However, more than half the patients had disease progression within the control period. The most commonly administered dose was 400 mg daily (5 patients) for 28 days cycle; only 2 patients tolerated higher doses and 6 patients received SBF as 300mg daily or less. There were delays in subsequent cycles in 10 of 12 patients, and the most common reasons for delays included cytopenias, liver function test abnormalities, and fatigue.

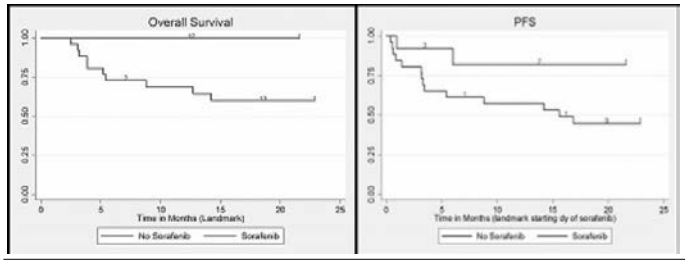

Figure 1.

Summary/Conclusions: Sorafenib maintenance is safe and can produce long term durable remissions after allogeneic stem cell transplant in a high risk population with FLT3-ITD mutated AML.

S793

A PHASE 1B STUDY OF THE COMBINATION OF VADASTUXIMAB TALIRINE AND 7+3 INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

[1]Baylor University Medical Center, Dallas, TX, [2]Gehr Family Center for Leukemia Research - City of Hope, Duarte, CA, [3]Ohio State University Comprehensive Cancer Center, Columbus, OH, [4]Colorado Blood Cancer Institute, Denver, CO, [5]Cleveland Clinic, Cleveland, OH, [6]Massachusetts General Hospital, Boston, MA, [7]John Theurer Cancer Center, Hackensack, NJ, [8]Fred Hutchinson Cancer Research Center, Seattle, WA, [9]Loyola University Medical Center, Maywood, IL, [10]Karmanos Cancer Institute, Detroit, MI, [11]Sarah Cannon Research Institute, Nashville, TN, [12]University of Washington Medical Center, Seattle, WA, [13]MD Anderson Cancer Center, Houston, TX, [14]Seattle Genetics, Inc., Bothell, WA, [15]University of Alabama-Birmingham, Birmingham, AL, United States

Background: For patients <65 yrs with newly diagnosed AML, standard induction treatment is continuous infusion of cytarabine for 7 days and an anthracycline for 3 days (7+3). Although a high percentage of patients achieve a CR by morphologic criteria, some requiring a 2nd induction, many are resistant to treatment or achieve a morphologic CR with evidence of minimal residual disease (MRD). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine dimer. Combining 33A with 7+3 could result in enhanced and deeper (MRD negative) remissions, resulting in reduced relapse rates and improved OS.
Aims: This phase 1b study (NCT02326584) evaluated the safety and antileukemic activity of escalating doses of 33A on 2 schedules: split dose (D1 and 4) or single dose (D1) with 7+3 induction therapy (cytarabine 100 mg/m^2 and daunorubicin 60 mg/m^2).
Methods: AML patients must be eligible for induction therapy. Response assessments occur on D15 and 28. Second induction and post-remission therapies were per investigator choice and did not include additional 33A. MRD was assessed centrally by bone marrow exam by a multiparametric flow at D15 and D28.
Results: *Split-dose cohort*: 42 patients (median age 45.5 yrs [range, 18-65]) were treated with 33A on D1 and 4 (10+10 [n=4] or 20+10 [n=38] mcg/kg) with 7+3. Most patients had intermediate (50%) or adverse (36%) cytogenetic risk. 19% had secondary AML. 2 patients had hematologic DLTs (lack of recovery of platelets [25K] and/or ANC [500] by D42) and 20+10 mcg/kg was determined to be MTD. The median time to count recovery from D1 of therapy in patients who achieved CR/CRi was 4.9 wks for ANC (≥1K) and 5.1 wks for platelets (≥100K). No non-hematologic TEAEs ≥G3 were reported in >10% of patients; non-hematologic TEAEs of any grade occurring in ≥25% of patients were nausea (62%), diarrhea, and constipation (38% each). Of the 42 efficacy evaluable (EE) patients, best responses included 25 CR (60%), 7 CRi (17%), and 5 morphologic leukemia-free state (mLFS; 12%) with a CR+CRi (CRc) rate of 76%; 23 of 25 (94%) responses were achieved in the 1st cycle. Of the patients with blast clearance (CR+CRi+mLFS), 73% (27/37) achieved MRD negative status. *Single-dose cohort*: To date, 25 patients (median age 58 yrs [range, 38-65]) were treated with 33A on D1 only (30 [n=14] or 40 [n=11] mcg/kg) with 7+3. Patients had intermediate (48%) or adverse (36%) cytogenetic risk. 16% had secondary AML. The median time to count recovery from D1 of therapy was 4.1 wks for ANC (≥1K) and 5.9 wks for platelets (≥100K) in patients who achieved CR/CRi. Four patients had hematologic DLTs, 1 at 30 and 3 at 40 mcg/kg. Non-hematologic TEAEs were consistent with those seen in the D1 and 4 schedule. Of the 24 EE patients, best responses included 12 CR (50%), 6 CRi (25%), and 3 mLFS (13%) with a CRc rate of 75%, achieved in 1st cycle. Of the evaluable patients with blast clearance, 89% (17/19) achieved MRD negative status. The CRc rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. Across schedules (N=67), the CRc rate was 76%; 79% (44/56) of evaluable patients with blast clearance achieved MRD negativity. The 30- and 60-day mortality rates were 1% and 7%, respectively. Median OS is not reached for either schedule and 52 patients (78%) were alive at the time of analysis.
Summary/Conclusions: 33A can be safely combined with 7+3 with acceptable count recovery in this population at the doses and schedules studied. Extramedullary AEs, including hepatotoxicity, and induction mortality rates were similar to reported rates for 7+3 alone in this AML population. A high remission rate with the 1st induction cycle was observed, the majority of which were MRD negative.

21-COLOR FLOW CYTOMETRY REVEALS IMMUNOPHENOTYPES ASSOCIATED WITH RESPONSE IN ACUTE GRAFT-*VERSUS*-HOST DISEASE PATIENTS TREATED WITH THE JANUS KINASE INHIBITOR INCB039110

K. Staser[1,*], J. Choi[1], J. Khoury[2], M. Jagasia[3], H. Ali[4], G. Schiller[5], M. Arbushites[6], P. Delaite[6], Y. Yan[6], K. Rhein[6], Y.-B. Chen[7], M.-A. Perales[8], L. Gehrs[1], J. Ritchey[1], J. DiPersio[1], M. Schroeder[1]
[1]Washington University in Saint Louis, Saint Louis, [2]Emory University School of Medicine, Atlanta, [3]Vanderbilt-Ingram Cancer Center, Nashville, [4]City of Hope, Duarte, [5]David Geffen School of Medicine at UCLA, Los Angeles, [6]Incyte Corporation, Wilmington, [7]Massachussetts General Hospital, Boston, [8]Memorial Sloan Kettering Cancer Center, New York City, United States

Background: Although ~50% aGVHD patients respond to steroids, no consensus second-line treatment exists. Recent preclinical models, retrospective studies, and this prospective trial have demonstrated safety and efficacy of JAK inhibitors (*e.g.* ruxolitinib, INCB039110) in steroid-refractory aGVHD.
Aims: Here, we present 21-marker FACS analysis of blood from patients enrolled in a prospective, randomized, parallel-cohort, open-label phase 1 trial of the potent and selective JAK1 inhibitor INCB039110 for aGVHD (NCT02614612). Preliminary results were previously presented at ASH 2016 (Schroeder et al).
Methods: Patients (n=30) were >18 years old undergoing first alloHSCT from any source with steroid-refractory or treatment-naïve grades IIB-IVD aGVHD, randomized 1:1 to 200 or 300 mg oral daily INCB039110 combined with corticosteroids. Peripheral blood, obtained at treatment days 7, 14, 28, 56, 100, and 180, was analyzed by 21-color FACS quantifying >30 cell types, including B, CD4+ and CD8+ T, memory T, T regulatory (Treg), Th1, Th2, Th17, T follicular helper (Tfh), Th9, Th22, ThGM-CSF cells, granulocytes, monocytes, monocyte-derived suppressor cells (MDSCs), natural killer cells (NKs), and monocytic and plasmacytoid dendritic cells (DCs). Patients were stratified by treatment response (*e.g.* complete response (CR), partial response (PR), mixed response (MR)).
Results: During INCB039110 treatment, overall B, T, and myeloid proportions did not correlate with response. However, the CR group showed increased NK cells (CD3-CD20-CD14-HLADR-CD56+), mDCs (CD3-CD20-CD14-HLADR+CD11c+), and memory CD4+ T cells (CD3+CD4+CD45RA-). Among CD4+ memory cells, the CR group showed significant or trend-toward-significant increases in Tfh (CCR10-CXCR5+), Th1 (CXCR5-CCR6-CCR10-CXCR3+), Th2, Th17 (CXCR5-CCR6+CCR4+CXCR3-CCR10-), ThGM-CSF (CXCR5-CCR6-CCR10+CXCR3-), and Th22 (CXCR5-CCR6+CCR4+CXCR3-CCR10+) cells. Tregs (CD4+CD25+CD127-) trended toward a ~2-fold increase in the CR group. Within the monocyte subgroup (CD3-CD20-CD14+), the CR group skewed toward classical monocytes (HLADR+CD16-) (64.7% *vs* 36.0%, CR *vs* PR/MR, p=0.0078) and away from MDSCs (HLADR-CD16-) (30.0% *vs* 58.4%, CR *vs* PR/MR, p=0.0139) during treatment. Interestingly, the NK-to-MDSC ratio was a sensitive and specific predictor of CR *vs* all other responses, a finding consistent for both CD16+ and CD16- NK cells (Figure 1 a, b). Before treatment, decreased naïve CD8+ T cells (CD45RA+CCR7+) predicted CR *versus* PR/MR (12.6% *vs* 32.3% of CD8+ cells, CR *vs* PR/MR, p=0.0047) with a similar trend toward decreased naïve CD4+ T cells (13% *vs* 24.4% of CD4+ cells, CR *vs* PR/MR, p=0.0749). While naïve T cells did not correlate with pre-treatment aGVHD grade, grades III-IV aGVHD demonstrated increased Th2 cells (CD45RA-CXCR5-CCR6-CCR10-CXCR3-) and activated CD8+ cells (CD38+HLADR+) as compared to grade II aGVHD. Further correlation with serum cytokines, JAK-STAT signaling, and pharmacology will be available at time of presentation.

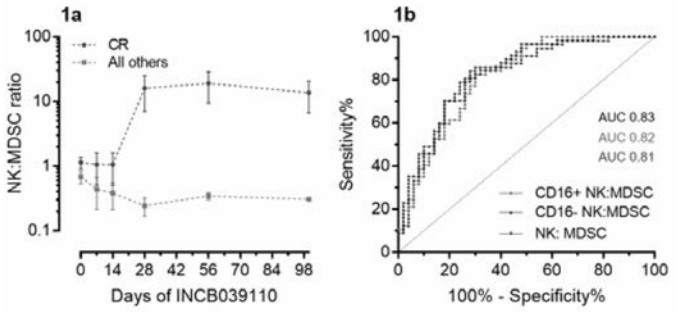

Figure 1.

Summary/Conclusions: Decreased pre-treatment naïve T cells may predict better outcomes in INCB039110-treated aGVHD. During treatment, increased DCs, NKs, and memory T cell subsets correlated with better response. Surprisingly, increased MDSCs associated with poorer response, suggesting MDSC expansion during persistent inflammation. The NK-to-MDSC ratio may be an important clinical marker to track treatment progress. Finally, this study establishes a novel FACS-based 21-marker immunophenotyping method with superior throughput, sample preservation, and flexibility as compared to cytometry time of flight (CyTOF) methods.

S795

GUT COLONIZATION BY MULTI-DRUG RESISTANT BACTERIA IS AN INDEPENDENT RISK FACTOR FOR DEVELOPMENT OF INTESTINAL ACUTE GRAFT-*VERSUS*-HOST DISEASE

Z. Peric[1,2,*], N. Durakovic[1,2], L. Desnica[1], V. Rezo Vranjes[3], I. Marekovic[3], R. Serventi-Seiwerth[1], J. Bilinski[4], G. Basak[4], R. Vrhovac[1,2]
[1]Hematology, University Hospital Centre Zagreb, [2]School of Medicine, University of Zagreb, [3]Department of Microbiology, University Hospital Centre Zagreb, Zagreb, Croatia, [4]Hematology, Medical University of Warsaw, Warsaw, Poland

Background: Research has recently highlighted the importance of healthy gut microbiota in the prevention of graft-*versus*-host disease (GVHD). Gut decontamination and the use of broad-spectrum antibiotics have led to the loss of natural microbiota diversity and the overgrowth of opportunistic pathogens with emerging antimicrobial resistence. However, the role of multi-drug resistant (MDR) bacteria in development of GVHD needs to be elucidated.
Aims: Our aim was to evaluate the impact of gut colonization with MDR bacteria on the acute GVHD and related outcome.
Methods: Retrospectively we evaluated 145 adult patients who consecutively underwent allogeneic stem cell transplantation (allo-SCT) in our institution between 2011 and 2014. All patients were weekly screened by cultivating stool specimens for gut colonization by the following MDR bacteria: vancomycin-resistant *Enterococcus* (VRE), methicillin-resistant *Staphylococcus aureus* (MRSA) and multidrug-resistant Gram-negative bacilli (MDR-GNB). Univariate and multivariable proportional hazards models using the Fine and Gray approach were considered to evaluate the variables for acute GVHD, treating death as competing event.
Results: Our study population included 88 male and 57 female patients who underwent allo-SCT at a median age of 46 years (range 18-64). Among them, most patiens were treated for myeloid malignancies (70%), while the rest had lymphoproliferative disorders and one patient had aplastic anemia. The donors were unrelated in 74 cases, related in 67 patients and haploidentical in 4 patients. Most of the patients (70%) received peripheral blood stem cells after a reduced-intensity conditioning regimen (56%). At the time of allo-SCT 37% patients were colonized with MDR bacteria, while another 19% became colonized in the early postransplantation period. Among colonized patients, 12% patients were colonized by VRE, 1% by MRSA, 43% by extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae, 27% by carbapenem-resistant Enterobacteriaceae (CRE), 9% by MDR *Acinetobacter baumannii* and 58% by MDR *Pseudomonas aeruginosa*. 36% patients were colonized with more than one MDR pathogen. The cumulative incidence (CI) of severe (grade III-IV) acute GVHD was significantly higher in patients colonized with MDR-GNB (27%, 95% CI, 19-39%) than in non-colonized patients (14%, 95% CI, 7-23%) (p=0.04). Moreover, MDR-GNB colonized patients had significantly more gastrointestinal (GI) GVHD CI as opposed to non-colonized patients (28% (95% CI, 20-41%) *vs* 14% (95% CI, 7-23%), p=0.02) and more acute GVHD-related mortality (16%, (95%CI, 9-26%) *vs* 7% (95%CI, 3-15%), p=0.10). A substantial and independent role of gut colonization with MDR-GNB on the development of GI GVHD was confirmed by multivariate analysis using time-dependent covariate functions for high risk disease, myeloablative conditioning, peripheral blood stem cells, unrelated donor (hazard ratio 2.14; 95%CI, 0.99-4.68, P=0.05), older age (hazard ratio 2.15; 95%CI, 1.00-4.59, P=0.04) and MDR-GNB gut colonization (hazard ratio 2.26;95% CI, 1.05-4.83, P=0.03).
Summary/Conclusions: In summary, this report shows a significant role of MDR-GNB in the pathogenesis of severe acute GVHD. To our knowledge, we are the first to show that gut colonization with MDR-GNB represents an independent risk factor for GI GVHD. With growing resistance and lack of efficient antibiotics, decolonization strategies as fecal microbiota transplantation become an attractive strategy for restoration of healthy gut flora and prevention of severe acute GVHD.

S796

IMPACT OF HLA DISPARITY ON OUTCOME IN HLA-HAPLOIDENTICAL BONE MARROW TRANSPLANTATION FOLLOWED BY HIGH DOSE POST-TRANSPLANT CYCLOPHOSPHAMIDE

L. Giannoni[1,*], A.M. Raiola[1], N. Sacchi[2], L. Garbarino[2], A. Dominietto[1], R. Varaldo[1], S. Bregante[1], C. Di Grazia[1], S. Aquino[1], A. Ibatici[1], F. Gualandi[1], M.T. Van Lint[1], T. Lamparelli[1], A. Risitano[3], A. Bacigalupo[4], E. Angelucci[1]
[1]Hematology, IRCCS AOU San Martino IST, [2]IBMDR , Ospedali Galliera , Genoa, [3]BMT Unit, Università Federico II, Naples, [4]Istituto Ematologia, Università Cattolica del Sacro Cuore, Rome, Italy

Background: By definition “haplo-identical” donors share genotipically 4/8 anti-

gens with recipients. However, casual phenotypical homozygosity in the non-shared haplotype makes the real degree of disparity less than 4/8 in a few donor/recipient couples.
Aims: Since 2010, patients who lacked a HLA-identical donor have been transplanted from a haploidentical donor in our two Italian institutions. In this large series of patients we aim to verify the real degree of antigen disparity between donors and recipients and whether it impacts on transplantation outcome.
Methods: All haplotransplants performed in two Italian istitutions from August 2010 to July 2016 (n =318) were included. All patients received a myeloablative regimen (MA) followed by unmanipulated bone marrow and high dose post-transplant cyclophosphamide (PT-CY), combined with cyclosporine and mycophenolate. Donors and recipients were typed, until 2015, using DNA method (SSO and SBT) for HLA A, B, C, DRB1, DQ and DPB at a high resolution level, as defined by EFI standards and by NGS at allelic level in 2016 for the same loci. When applicable (72,3% of patients) members of the immediate family where typed to definitively establish HLA genotype and haplotype identity. Differences at loci A, B, C, DRB1 in both GvH and HvG direction were evaluated. We evaluated overall survival (OS) and non-relapse mortality (NRM) according to the amount of overall mismatches; also, we analyzed cumulative incidence of grade II – IV aGVHD, moderate-severe chronic GvHD and relapse (CIR) according to the degree of HLA mismatches in the GVH direction and graft rejection rate according to the degree of HLA mismatches in the HVG direction. For analysis purpose, the whole patient population was divided into 2 groups: 0-1-2 antigen mismatches *versus* 3-4 antigen mismatches. The same distinction was mantained when analyzing only GVH or HVG directed mismatches. Acute GvHD was calculated at day 100, the other parameters were calculated at the second year of follow up. OS was estimated using the Kaplan-Meier approach while cumulative incidence was calculated for aGvHD, cGvhD, relapse and NRM.
Results: Median age of patients was 48 years (17-74). Diagnoses included acute myeloid leukemia (130), acute lymphoblastic leukemia (64), lymphoid and plasma cell malignancies (43), myeloproliferative neoplasms (48) and myelodisplastic syndrome (33). 144 patients (45%) were transplanted in advanced phase of disease. With a median follow up of 562 days (range 6-2241 days), 2-year OS was 55,7%. Concerning the proportion of "true" haploidentical D/R pairs, 231 out of 318 (72%) couples showed 4/8 mismatches at HLA A, HLA B, HLA C and HLA DRB1 loci. Neither OS nor NRM showed significant correlation with the degree of overall mismatches at 2 years (0-2 mm: 54.2% *vs* 3-4 mm:58.8%, p=0.58 and 0-2 mm:18.2% *vs* 3-4 mm:19.1%, p=0.93, respectively). Considering only GVH directed mismatches, no difference was highlighted between low or high HLA mismatch burden in cumulative incidence of aGVHD (12.6% *vs* 23.9%, p=0.13), cGVHD at 1 year (12.2% *vs* 14.8%, p=0.84) and relapse (33.3% *vs* 24%, p=0.26). In this series graft rejection rate was 6.6%; no correlation was observed with the amount of HLA mismatch in the HVG direction.
Summary/Conclusions: In this series, about one third of haploidentical donor/recipient pairs differ for less than 4 /8 HLA antigens. Furthermore, in the setting of a MA conditioning with PT-CY the real degree of HLA mismatching observed had no impact on OS, NRM, CI of Relapse and acute and chronic GvHD.

Background: Allogeneic hematopoietic stem cell transplantation (alloHCT) is widely used for the treatment of adults with acute lymphoblastic leukemia (ALL). Although the choice of pre transplantation conditioning has never been a subject of a randomized trial, results of many retrospective studies suggested advantage of total body irradiation (TBI)-based over chemotherapy-based regimens. TBI is most frequently administered in combination with either cyclophosphamide (Cy/TBI) or etoposide (Vep/TBI).
Aims: The goal of this study was to retrospectively compare the outcome of alloHCT using Cy/TBI or Vep/TBI as conditioning.
Methods: Adult patients with Ph-negative ALL (n=1498) treated with alloHCT from either HLA-identical sibling (n=696) or unrelated donor (n=802), in CR1 (n=1186) or CR2 (n=312), between year 2000 – 2015, were included in the analysis. Peripheral blood was used as a source of stem cells in 62% of the patients, while bone marrow in 38% of the patients, respectively. Conditioning was myeloablative in all cases (the median TBI dose was 12Gy); 1346 patients were treated with Cy/TBI while 152 patients with Vep/TBI. Patients in the Vep/TBI group were younger (median 28 y. *vs* 30 y., p=0.04), treated in more recent period (median year of HCT: 2009 *vs* 2007, p=0.009) and treated more frequently in CR1 (87% *vs* 78%, p=0.001).
Results: In a univariate analysis, as compared to Cy/TBI, the use of Vep/TBI was associated with significantly reduced incidence of relapse (17% *vs* 30% at 5 years, p=0.007), increased rate of leukemia-free survival (LFS, 60% *vs* 50%, p=0.04) as well as improved "GVHD and relapse-free survival" (GRFS, 43% *vs* 33%, p=0.04). No significant effect could be observed in terms of the incidence of non-relapse mortality, acute or chronic GVHD. In a multivariate model the use of Vep/TBI was associated with reduced risk of relapse (HR=0.62, p=0.04) while the effect on other study end-points was no longer significant. Among other factors, recipient age (HR=1.17 per every 10 years, p=<0.0001), year of alloHCT (HR=0.97 per every year, p=0.001) and disease stage (HR=2.14 for CR2, p<0.0001) had significant influence on the risk of treatment failure, either relapse or non-relapse mortality. The risk of relapse was additionally increased for sibling *vs* unrelated donor transplants (HR=1.47, p=0.01) and donor/recipient gender combination other than female/male (HR=1.37, p=0.04).
Summary/Conclusions: Conditioning regimen based on etoposide combined with TBI appears more effective than the cyclophosphamide TBI combination for adult patients with Ph-negative ALL treated with alloHCT. Further, prospective studies are needed to confirm our observation and potentially discriminate subgroup of patients who are most likely to benefit from the use of etoposide.

Marquès de Valdecilla, Santander, Spain, [16]Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands, [17]Medicine-Hematology-Oncology, University of Freiburg, Freiburg, Germany, [18]Hematology, Hospital Clinic, Barcelona, Spain, [19]Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: High-risk acute myeloid leukemia (AML) is mainly defined by the presence of determined poor-risk cytogenetic abnormalities and is a standard indication for allogenetic stem cell transplantation (SCT). Nevertheless, high-risk AML is a very heterogeneous group including several abnormalities with different levels of prognostic impact. Deletion 5q or monosomy 5 (-5/5q-) has been part of the high-risk group of AML for many years. SCT seems to improve their outcomes but the additive effects of other high-risk cytogenetic features on survival have never been thoroughly studied.
Aims: To evaluate the role of SCT in -5/5q- AML with additional cytogenetic abnormalities such as complex karyotype (CK), monosomal karyotype (MK), monosomy 7 (-7), or 17p abnormalities (abn(17p)).
Methods: We included adult patients (pts) with AML with -5/5q- reported to the EBMT registry as having their first SCT between 2000 and 2015.
Results: Five hundred and one pts, 21% of them with secondary AML, have been allocated. Median age at SCT was 55 year-old (range, 18-75) and median follow-up was 21 months (range, 2-173). At time of SCT, 338 pts (67%) were in first remission (CR1), 21 pts (4%) were in subsequent remission and 142 (28%) had active disease. Two hundred seventy-seven pts (55%) were transplanted from an unrelated donor (UD) and 224 from a sibling donor. A myeloablative conditioning (MAC) was administered in 45% of the pts and a reduced-intensity conditioning (RIC) in 55% of them. The 2-year probabilities of overall survival (OS) and leukemia-free survival (LFS) were 27% and 20%, respectively. The 2-year probality of treatment-related mortality (TRM) was 20%. The cumulative incidence of grade II-IV acute graft-*versus*-host disease (GvHD) was 29% and the 2-year cumulative incidence of chronic GvHD was

27%. The main cause of death was disease-related. In multivariate analysis, active disease correlated strongly with worse OS, LFS and NRM. The other factors influencing outcomes were UD with increased NRM, and age with decreased OS and LFS.
Based on the frequencies of the different additional cytogenetic abnormalities, we identified 4 groups within our cohort. Group 1 (None) included 47 pts with -5/5q- but without CK, MK or abn(17p). Group 2 (CK) included pts with -5/5q- and CK but no MK or abn(17p) (N=90). Group 3 (MK) included 169 pts with -5/5q- and MK but no abn(17p). Finally, group 4 (17p) included pts with -5/5q- and abn(17p) (N=193). The 4 groups were quite similar in term of characteristics. The 2-year probablity of LFS was 39% for group 1, 25% for group 2, 20% for group 3 and only 13% for group 4 (p<0.001). OS decreased also significantly from group 1 to group 4 (p<0.001). NRM was similar across the groups. In multivariate analysis, factors associated with worse OS and LFS were active disease, age, MK and abn(17p). The corresponding 2-year probability of GvHD and relapse-free survival was 27% for group 1, 17% for group 2, 14% for group 3 and 7% for group 4 (Figure 1).

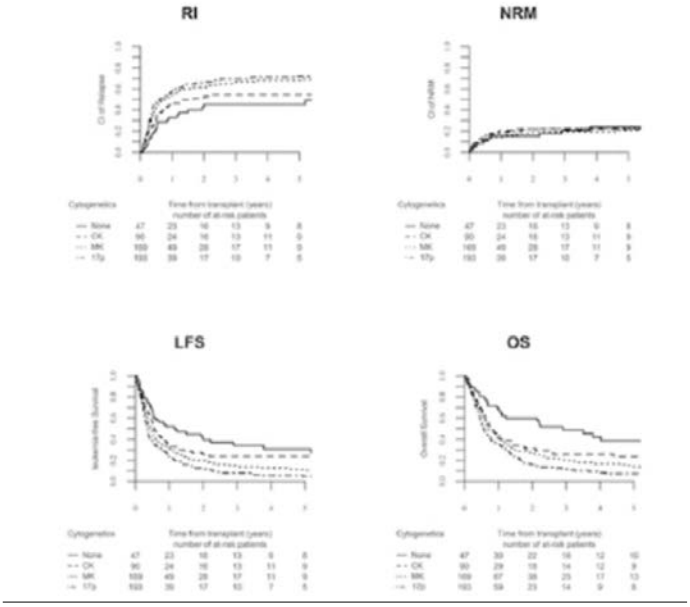

Figure 1.

Summary/Conclusions: SCT in -5/5q- AML provides a durable response for approximately 20% of pts. Active disease at time of transplantation was the most powerful predictor of an inferior outcome. The presence of -5/5q- without CK, MK or abn(17p) was associated with a significant better survival and the addition of MK or abn(17p) translated into worse outcomes. We confirmed the deleterious effect of the combination of -5/5q- and abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve their outcome.

Background: T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) accounts for 10% to 15% of newly diagnosed cases of childhood acute lymphoblastic leukemia (ALL), arising from the malignant transformation of hematopoietic progenitors primed toward T cell development, as result of a multistep oncogenic process. However, since the prognostic significance of these genetic alterations in pediatric T-ALL is not clear, genetic basis which contributes aggressive phenotype or progression of pediatric T-ALL is still to be elucidated.
Aims: To discover driver genetic events, which involved in the aggressive phenotype of pediatric T-ALL and to identify its novel prognostic markers, we performed integrated genetic analysis in a large cohort of T-ALL case.
Methods: Our cohorts included samples from Tokyo Children's Cancer Study Group (TCCSG) and Japan Association of Childhood Leukemia Study (JACLS). Whole transcriptome sequencing (WTS) was performed in 123 cases. Whole transcriptome sequencing (WTS) was performed in 123 cases.
Results: Representative recurrent fusion genes were as follows, *SIL-TAL1* (n=25), *MLL-ENL* (n=5), *PICALM-MLLT10* (n=5), and *NUP214-ABL1* (n=2). Intriguingly, novel recurrent in-frame *PU.1* fusions (*STMN1-PU.1* n=2; *TCF7-PU.1* n=5) were detected, and RT-PCR analysis in additional 60 cases revealed other 2 *TCF7-PU.1* fusions. Thus, *PU.1* fusions accounted for 4% of pediatric T-ALL/LBL. Expression data of WTS revealed cases with *PU.1* fusion showed significantly higher expression of PU.1 compared to cases without *PU.1* fusion, implicating that aberrant high expression of *PU.1* involved in leukemogenesis. Using consecutive two-step unsupervised consensus clustering, we obtained 5 stable clusters. Among these, 4 clusters largely recapitulated distinct T-ALL subtypes characterized in previous studies by an early T-cell precursor (ETP) signature (ETP-ALL), 2 clusters of high *TAL1* expression (TAL1-RA and -RB -ALL), and mutually exclusive expression of, *TLX1*, and *TLX*3 (TLX-related-ALL). However, the remaining one was newly identified and exclusively consisted of the 7 *PU.1* fusion-positive cases. Compared to ETP-ALL, these *PU.1* fusion cases typically showed a reduced expression of the phase I genes implicated in early T-cell development**,** except for *PU.1*, which was ectopically upregulated by the relevant gene fusions. All cases with *PU.1* fusion were grouped into *PU.1* high cluster. Moreover, *PU.1* high cluster had distinct genetic features with mutations of transcription factors, such as *GATA3*, *RUNX1*, and *EVT6.* Of note, significant poor outcome was confirmed by multivariate analysis in cases with *PU.1* high cluster (p=0.048). Consistently, we defined *PU.1* overexpression cases as outliers of *PU.1* expression, which resulting in extremely poor prognosis (3-year OS 21%, log-rank p=6.9 $\times 10^{-7}$).
Summary/Conclusions: *PU.1* fusions expressing cells expanded and they remained at an immature stage, implicating a potential leukemogenic activity of these fusions. Not only the cases with *PU.1* fusions, but also the cases with

high *PU.1* expression without fusions showed extremely poor prognosis, suggesting the prognostic value of aberrant *PU.1* expression in pediatric T-ALL. Although it remains unclear, why cases with *PU.1* fusions/high *PU.1* expression have a poor prognosis, our results indicate that these cases are genetically distinct subgroup from other pediatric T-ALL.

S800

PROGNOSTIC IMPACT OF ADDITIONAL MOLECULAR LESIONS IN PH+ ACUTE LYMPHOBLASTIC LEUKEMIA

A.L. Fedullo[1], M. Messina [1], A. Vitale[1], L. Elia[1], A. Piciocchi[2], V. Gianfelici[1], A. Lauretti[1], A. Guarini[1], S. Chiaretti[1,*], R. Foà[1]
[1]Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University, [2]GIMEMA Data Center, Rome, Italy

Background: The outcome of Ph+ acute lymphoblastic leukemia (Ph+ ALL) has drastically improved since the introduction of tyrosine kinase inhibitors (TKI). At present however, well-defined prognostic markers, beyond the monitoring of minimal residual disease (MRD) during follow-up and to a lesser extent *IKZF1* deletions, are lacking.
Aims: To identify genomic lesions of prognostic value, we evaluated copy number aberrations (CNA) by SNP arrays, confirmed them by multiplex ligation-dependent probe amplification (MLPA) and we set up a droplet digital PCR (ddPCR) assays for additional lesions. Furthermore, we correlated the lesions identified with MRD monitoring, outcome and biological features, such as the type of fusion protein (p190 or p210). Finally, in a subset of patients gene expression profiling (GEP) was carried out.
Methods: Genomic DNA of 116 newly diagnosed adult Ph+ ALL patients enrolled in 4 consecutive GIMEMA trials, namely 0201B, 0904, 1205 and 1509, was evaluated. All the trials were based on an induction with steroids and TKI, the first 2 with imatinib and the remainders with dasatinib. For CNA, the Cytoscan HD Arrays (Affymetrix, Santa Clara, CA) were used. The lesions were confirmed by MLPA on all samples using the Salsa MLPA P335-A3 ALL-*IKZF1* kit (MRC-Holland, Amsterdam, The Netherlands). ddPCR was used to validate lesions targeting *MEF2C*. In 42 cases, GEP experiments were performed using the HGU133 Plus 2.0 gene chips (Affymetrix, Santa Clara, CA).
Results: We found a similar load and type of lesions across the 4 trials, one of which included elderly. The majority of lesions targeted *IKZF1* (84%), *PAX5* (36%) and *CDKN2A/B* (32%). In our cohort, *IKZF1* deletions alone did not affect complete molecular response (CMR) achievement or disease-free survival (DFS), while patients harboring *CDKN2A/B* and *PAX5* deletions had a significant inferior outcome (p=0.004, p=0.003 respectively). In line with this, a worse DFS was observed for the so-called "*IKZF1* plus" cases, *i.e.* concomitant deletions of *IKZF1* and *CDKN2A/B* and/or PAX5 (46% *vs* 24% at 36 months, p=0.005). MLPA confirmed the incidence of these deletions and allowed the study of *IKZF1* isoforms. Among *IKZF1* deleted cases, patients carrying the Δ4-7 isoform (25%) had a worse DFS (p=0.02) than patients harboring other *IKZF1* isoforms. Importantly, SNP arrays highlighted novel genomic lesions targeting *MEF2C* in 13% of cases, which were associated to the achievement of a CMR (p=0.05) and had a significant impact on DFS (62% *vs* 32% at 36 months, p=0.02). The association with CMR was not affected by the trial (p=0.76) or the TKI used (p=0.57). This result was confirmed by ddPCR. Unsupervised hierarchical clustering of GEP experiments identified 3 subgroups: the first comprised mainly patients who reached a CMR, the second one patients who had *IKZF1* alone, and the last one comprised "*IKZF1 plus"* patients. ANOVA analysis showed an overexpression of genes involved in cell communication and protein modification process in *PAX5* deleted cases, suggesting that these genes could be contributing factors in BCR/ABL1-driven leukemogenesis.
Summary/Conclusions: In adult Ph+ ALL, *IKZF1* deletions have a prognostic impact only if associated with other lesions. Among *IKZF1* deletions, only the Δ4-7 deletion has a deleterious effect. *MEF2C* lesions carry prognostic implications, being significantly associated with a better prognosis. This study paves the way to design a prognostic model for adult Ph+ ALL that includes these findings and more conventional features, in order to better stratify patients at diagnosis and to further optimize treatment.

S801

MULTI-CENTER VALIDATION OF STANDARDIZED NGS ASSAYS FOR REARRANGED IG / TR MARKER DETECTION IN ACUTE LYMPHOBLASTIC LEUKEMIA – A REPORT OF THE EUROCLONALITY-NGS CONSORTIUM

Background: Amplicon-based next generation sequencing (NGS) of immunoglobulin (IG) and T-cell receptor (TR) gene rearrangements can be used to identify suitable markers for subsequent quantification of minimal residual disease (MRD) in acute lymphoblastic leukemia (ALL). Within the EuroClonality-NGS Consortium we established and validated a standardized quality controlled amplicon-based NGS application to detect clonally rearranged IGH, IGK, TRB, TRG and TRD genes in lymphoid disorders.
Aims: 1) to test EuroClonality-NGS IG / TR NGS assays within an international multi-laboratory pilot for their suitability to identify clonal markers in ALL at diagnosis, and 2) to compare these NGS results with conventional Sanger sequencing (SS) of Genescan or Heteroduplex peaks/bands local multiplex PCRs
Methods: Within the EuroClonality-NGS Consortium, V, D, and J gene-specific primers tailed with universal and T7-linker sequences, were designed to amplify complete and incomplete IGH, IGK, TRB, TRG or TRD gene rearrangements employing eight different multiplex PCR assays. PCR protocols were standardized in a common NGS workflow for all targets. NGS assays were tested in a European multi-laboratory pilot run in five institutes (Kiel, Bristol, Prague, Monza, Paris). Diagnostic DNA (100ng) from 10 ALL patients per centre were amplified in each institute using the EuroClonality NGS primer sets, and subsequently sequenced on the Illumina MiSeq (2×250bp v2 kit). Defined copy numbers of clonal reference DNAs were spiked into all samples for calculation of clonotype copy numbers. A standard polytarget quality control (QC) DNA was used to monitor inter- and intra-lab NGS reproducibility. Results of NGS based marker identification were compared to results of routine SS results.
Results: Fifty ALLs (29 BCP-ALL and 21 T-ALL) were analysed. A total of 480 libraries were deep sequenced, leading to 47 M high quality reads (≈ 9.2 M/lab). Pre-processing, identification and immunogenetic annotation of target sequences, quality control and copy number calculations, were performed with ARResT/Interrogate, using IMGT germline sequences – further analyses and verifications were performed with Vidjil and IMGT/V-QUEST. Overall, 339 clonal IG / TR sequences were identified, with a mean of 6.3 (2-13)/sample using NGS *vs* 5.0 (2-13)/sample using SS. A total of 228/339 (68%) clonal sequences were concordant between both methods. NGS identified additional clonal rearrangements in 88 (26%) libraries, whereas 23 (7%) clonal markers were only detected by SS. NGS primers covered possible IG /TR rearrangement types more completely compared to local multiplex PCR sets and enabled sequencing of bi-allelic rearrangements and weak PCR products. Currently discrepant cases are analysed in more detail using allele-specific PCR assays. Assay performance was analysed by standardized evaluation of QC samples and showed high intra- and inter-lab consistency without statistically significant differences between the labs.
Summary/Conclusions: The IG / TR NGS panel, as established by the EuroClonality-NGS Consortium, allows for quality controlled high-throughput detection of clonal IG /TR rearrangements in ALL. Compared to low throughput methods more clonal MRD markers are identified, sensitivity is increased, processing time is reduced and labour intensive conventional methods to resolve mixed sequences in case of bi-allelic rearrangements or background are avoided.

S802

POST-INDUCTION MRD PREDICTS HIGH RELAPSE RISK FOLLOWING REDUCED INTENSITY CONDITIONED ALLOGENEIC STEM CELL TRANSPLANTATION: A PROSPECTIVE STUDY OF ADULT ALL (UKALL14,ISRCTN 66541317)

D. Okasha[1,2,*], A.A. Kirkwood[3], B. Wrench[4], E. Lawrie[3], K. Zuborne Alapi[1], L. Clifton-Hadley[3], N. Morley[5], P. Patrick[3], R. Mitchell[1], T. Naughton[1], D.I. Marks [6], A.K. Fielding[7]
[1]Cancer Institute, UCL, London, United Kingdom, [2]Faculty of Medicine, Alexandria University, Alexandria, Egypt, [3]Cancer Trial Centre, [4]Barts Cancer Institute, QMUL, London, [5]Royal Hallamshire Hospital, Sheffield, [6]University Hospitals Bristol NHS Trust, Bristol, [7]Department of Haematology, Cancer Institute, UCL, London, United Kingdom

Background: Reduced intensity conditioned allogeneic haematopoietic stem cell transplant (RICalloHCT) enables HCT to be performed in older patients. The UK NCRI UKALL14 study of adult acute lymphoblastic leukaemia (ALL) considers patients ≥41 years "high risk" and recommends a RICalloHCT where there are high quality donors. Other "high risk" factors are high WBC at presentation, t(9;22), t(4,11), hypodiploidy/near triploidy, complex karyotype and positive minimal residual disease (MRD) after completing induction therapy. The presence of MRD at this time-point predicts poor outcome after conventional chemotherapy. There is evidence that myeloablative alloHCT can overcome this risk, but the benefit of RICalloHCT is uncertain.
Aims: To determine whether RICalloHCT mitigates the high relapse risk predicted by MRD positivity after induction therapy.
Methods: Protocol treatment: patients receive a steroid pre-phase before 2 cycles of induction chemotherapy. At the end of induction, patients are assigned subsequent therapy on the basis of risk. All patients over 41 years are allocated RICalloHCT, conditioned with fludarabine, melphalan and alemtuzumab. Post HCT, escalating doses of donor lymphocyte infusions were given for T-cell mixed chimerism +/- MRD persistence or relapse. MRD assessment: *BCR/ABL1* or Ig/TCR MRD was assessed and analysed per EuroMRD guidelines. MRD is negative (undetectable with an assay quantitative range of $1x10^{-4}$ or less), positive (≥$1x10^{-4}$), positive outside quantitative range (POQR)(<$1x10^{-4}$) or indeterminate (undetectable but assay quantitative range ≥$5x10^{-4}$). Patients with indeterminate MRD were excluded from this analysis.
Results: There are 736 patients randomised to date, of whom 184 received a RICalloHCT; of these, 115 had analysable MRD. The following Table 1 shows patient characteristics.

Table 1.

Patient characteristics	n=115	Disease characteristics	n=115
Age at randomisation median (range)	49 (30-65)	B-ALL	100 (87)
Presenting WBC median (range)	8.6 (0.1-557)	T-ALL	15 (13)
Sex N (%)		**High-risk cytogenetics** N (%)	
Male	61 (53)	*BCR/ABL1* N (%)	39 (33.9)
Female	54 (47)	t(4,11)	6 (5.2)
Donor type N (%)		Hypodiploidy/near triploidy	7 (6.1)
Sibling	40 (34.8)	Complex karyotype	3 (2.6)
Matched unrelated	75 (65.2)	**UKALL14 cytogenetic risk group** N (%)	
Post induction MRD N (%)		Standard	42 (36.5)
Negative/POQR	77 (67)	High risk	53 (46.1)
Positive	38 (33)	Unknown	20 (17.4)

At 2 years post transplant, overall survival (OS) was 63.1% in the 115 patients with evaluable MRD and 62.7% in the 184 patients receiving RICalloHCT; event free survival (EFS) was 55.2% and 55.9% respectively. By contrast, in the 38 of 115 patients with positive MRD after induction, OS and EFS were 40.6% and 28.4% respectively. Twenty eight of the 115 patients relapsed, with a 2 year actuarial relapse risk of 31.5% (22.2-43.5). We assessed the association of the following factors; age, sex, immunophenotype, presenting WBC, *BCR/ABL1*, other cytogenetics, post-induction MRD and donor type with the risk of relapse. Among this population of high risk patients, post-induction MRD was the only independent prognostic factor for relapse (univariable HR: 3.82 (1.59–9.16), p 0.001 (see Figure 1) and multivariable HR: 4.14 (1.61-10.65), p= 0.003). The relapse rate of the MRD+ patients was 57.2% at 2 years post HCT.

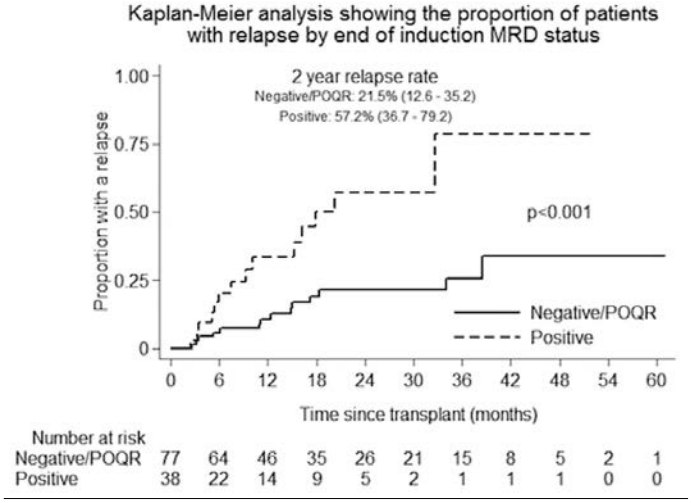

Figure 1.

Summary/Conclusions: The 2-year OS of 62.5% in UKALL14 participants over 41 years old after RICalloHCT is greater than would be expected with chemotherapy alone. However, MRD positivity after induction is associated with significantly lower OS, EFS and a higher risk of relapse, which is not abrogated by RICalloHCT.

S803

T-CELL RECEPTOR B REPERTOIRE CHARACTERISTICS IN RELAPSED/REFRACTORY B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA ON BLINATUMOMAB TREATMENT

H. Knecht[1,2], M. Kotrova[1,2,*], T. Reigl[3], A. Krejci[3], D. Herrmann[2], M. Schwarz[2], V. Bystry[3], N. Darzentas[3], M. Brüggemann[2]
[1]contributed equally, [2]Department of internal medicine II, Laboratory for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, Germany, [3]Central European Institute of Technology, Brno, Czech Republic

Background: Blinatumomab (Blin) is a bispecific monoclonal antibody, activating autologous effector T-cells and redirecting them against CD19-positive malignant cells. This leads to polyclonal effector T-cell expansion which is the necessary component of its antitumour mechanism. Recent reports indicated promising antitumour activity of Blin in relapsed/refractory (r/r) B-cell precursor acute lymphoblastic leukemia (BCP-ALL). However, approximately half of these patients do not achieve minimal residual disease (MRD) response.
Thanks to recent advances in next generation sequencing (NGS) of immunoglobulin and T-cell receptor gene rearrangements the deep and comprehensive evaluation of expanded T-cell repertoire on Blin treatment is now possible.
Aims: To compare the differrences in TRB repertoire diversity and composition between two groups of patients with r/r ALL: 1) responders: reaching MRD negativity at the latest at day 29 of 1. Blin cycle (C1D29), and 2) persisters: with quantifiable MRD positivity (>0.01%) at C1D29, or with MRD >1% at cycle 1 day 15 (C1D15) if C1D29 sample is not available.
Methods: We used NGS to investigate TRB repertoire in bone marrow samples (114× at time of screening (scr), 74× C1D15, 98× C1D29) of 114 r/r Ph-negative BCP-ALL patients (median age: persisters 47; responders 42; p-value=0.81). Patients received Blinatumomab within the phase II trial (MT103-211). Sequencing libraries were prepared using 100ng of DNA via 2-step PCR and sequenced on the Illumina MiSeq (2 x 250bp) with a median coverage of 117,563 reads (range 59.512 - 447.767 reads) per sample. In the first PCR virtually all TRB rearrangements present in the investigated sample were amplified using universal V(D)- and J-regions primers. In the second step, sequencing adaptors and sample-specific barcodes were added. Annotation of V (D)- and J-regions of TRB sequences was performed using ARResT/Interrogate (Bystry, Bioinformatics, 2016). Diversity of TRB repertoire within patient groups and time points was expressed as the Shannon index, using the R-package *vegan*. Analysis of variance was employed to assess statistically significant differences in diversity between groups and time.
Results: Diversity of TRB repertoire (Figure 1) was significantly higher in responders at time of scr (p=0.02) and at C1D29 (p=5.47E-6). Patients in the persisters group had significantly higher blast counts, which is in accordance with previously published data (Topp, The Lancet Oncology, 2015). The increase of diversity between scr and C1D29 of Blinatumomab treatment was sharp and highly significant in responders (p=3.96E-6), but not statistically significant in persisters (p=0.4).

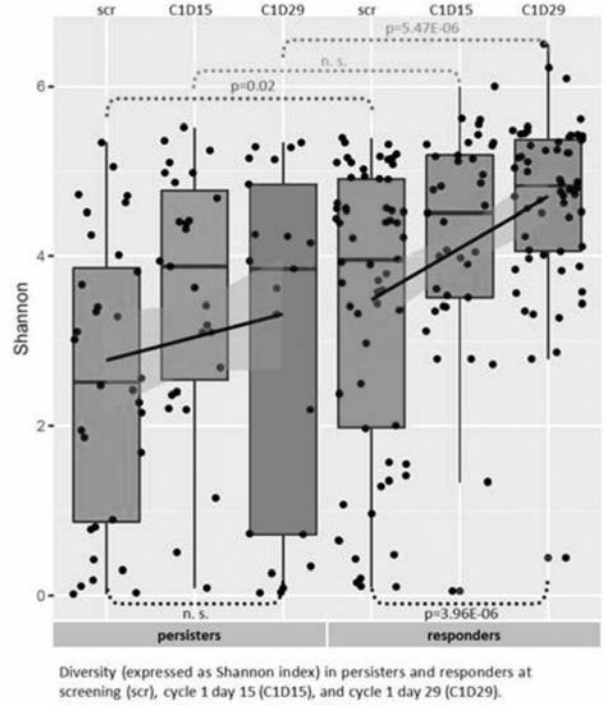

Figure 1.

Summary/Conclusions: We showed that Blin responders have significantly higher TRB repertoire diversity at scr compared to persisters and that the repertoire expansion during Blin treatment is sharper in responders. Other repertoire characteristics did not differ significantly between groups. Further studies on larger patient cohorts are necessary in order to elucidate whether the response to treatment can be predicted by repertoire diversity at scr.
Amplicon NGS is a useful tool for monitoring of T-cell repertoire. Development, standardization, and validation of TRB primer sets is in progress within Euro-Clonality-NGS Consortium.

DISCONTINUING ANTIBACTERIAL THERAPY AFTER APYREXIA AND CLINICAL STABILITY REGARDLESS OF NEUTROPHIL COUNT IN FEBRIL NEUTROPENIA IS SAFE AND REDUCES EXPOSITION TO ANTIBIOTICS (HOWLONG RANDOMIZED TRIAL)

I. Espigado[1,*], M. Aguilar-Guisado[2], A. Martín-Peña[2], C. Gudiol[3], J. Falantes[1], L. Vazquez[4], I. Montero[1], M.L. Martino[1], R. Parody[1], J. Gonzalez-Campos[1], S. Garzon[5], C. Calderon-Cabrera[1], P. Barba[6], N. Rodriguez-Torres[1], M. Rovira[7], J.A. Perez-Simon[1], J.M. Cisneros-Herreros[2]
[1]Unidad Clínica de Hematología, [2]Unidad Clínica de Enfermedades Infecciosas, Microbiología y Medicina Preventiva, Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, [3]Servicio de Enfermedades Infecciosas, Hospital de Bellvitge, Barcelona, [4]Servicio de Hematología, Hospital Clínico de Salamanca, Salamanca, [5]Servicio de Hematología, Hospital de Jerez de la Frontera, Jerez, [6]Servicio de Hematología, Hospital Universitario Vall´Hebron, [7]Servicio de Hematología, Hospital Clinic, Barcelona, Spain

Background: In neutropenic patients with unexplained fever the classical approach is maintaining the empirical antibacterial therapy (EAT) until neutrophil recovery. This strategy may result in unnecessarily prolonged EAT favoring bacterial resistance, organ toxicity and damage to microbiota. Nevertheless, the available scientific evidence supporting the alternative approach of stopping EAT before neutrofile recovery is moderate.
Aims: To investigate if a clinical approach (based on apyrexia and clinical recovery) is better than and as safe as the standard criteria (recovery from neutropenia) to decide the discontinuation of EAT.
Methods: After local Ethical Committee approval, a randomized, controlled, multicenter, open-labeled phase IV clinical trial was performed (EudraCT: 2011-005152-34). Study period: May-2012 to May-2016. Inclusion criteria: a) Adult patients (≥18 years); b) Hematologic malignancy or autologous or allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x106/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.
Results: One hundred and fifty seven patients were included (EG 78 and CG 79). There were no differences in baseline characteristics or clinical presentation between groups. The most frequent underlying conditions were induction/re-induction chemotherapy for acute leukemia (n=42, 26,7%), autologous SCT (n=42, 45,8%), and allogeneic SCT (n=14, 8,9%). The most frequent clinical presentation was non-focused FN (n=63, 40,1%), abdominal focused FN (n=34, 21,6%) and mucositis (n=31, 19,7%). Days with fever, and neutropenia duration and EAT-free days difference between groups are detailed in Table 1. Recurrent fever frequency was 14,3% (EG) and 17,9% (CG) (p=ns) and crude mortality was 1,3% (EG) and 3,8% (CG) (p=ns).

Table 1.

Neutropenia, fever duration and EAT-free days.

Variables	Median (IQ range)	Median (IQ range)	
ITT population	EG (n=78)	CG (n=79)	*P*
Days of neutropenia	14 (9,5-24)	11 (8-21)	*p*=ns
Days of fever	4 (2-8)	4 (2-8)	*p*=ns
EAT-free days*	18 (12,5-21,5)	16 (9,7-20,2)	*p*=0,047
Per protocol population	EG (n=66)	CG (n=66)	
Days of fever	4 (1-14)	5 (2-8,2)	*p*=ns
EAT-free days*	19 (14-22)	14,5 (8,7-20)	*p*=0,02
Modified per protocol population [#]	EG (n=36)	CG (n=30)	
Days of fever	3 (1-7,2)	3 (1-5,7)	*p*=ns
EAT free-days*	20 (11,2-23)	11,5 (5-16,7)	*P*<0,001

ITT: Intention to treat; EAT: empirical antimicrobial therapy; EG: experimental group; CG: control group. IQ range: interquartile range.
*EAT free-days: days of follow-up (28) – days of EAT.
[#]Patients in which clinical recovery and neutropenia recovery did not match.

Summary/Conclusions: In hematological patients with febrile neutropenia of unknown origin the discontinuation of empirical antibacterial therapy after 72 hours of apyrexia and clinical recovery regardless of neutrophils count is safe and reduces unnecessary exposure to antibiotics.

S805

CONJUGATED PNEUMOCOCCAL VACCINE TRIGGERS A BETTER IMMUNE RESPONSE THAN POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA A RANDOMIZED STUDY BY THE SWEDISH CLL GROUP

T. Svensson[1,*], M. Kättström[2], Y. Hammarlund[3], D. Roth[4], P.-O. Andersson[5], M. Svensson[6], I. Nilsson[7], L. Rombo[6], H. Cherif[8], E. Kimby[9]
[1]Section of Heamatology, Institution of Medical Sciences, Uppsala, [2]Department of Medical Sciences, Örebro University Hospital, Örebro, [3]Falun Hospital, Falun, [4]Institution of Clinical Sciences, Faculty of Medicine, Lund University Hospital, Lund, [5]Hematology and Coagulation Section, Sahlgrenska University Hospital, Göteborg, [6]Eskilstuna Hospital, Eskilstuna, [7]Karlstad Hospital, Karlstad, [8]Section of Haematology, Institution of Medical Sciences, Uppsala, [9]Department of Medicine, Unit of Hematology, Karolinska Institute and University Hospital, Huddinge, Sweden

Background: Patients with CLL have an increased risk for infection and *Streptococcus pneumoniae* is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.
Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13®, compared with a 23-valent capsular polysaccharide vaccine (PPSV23), Pneumovax®, in terms of immune response.
Methods: 128 treatment naïve CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytic assay (OPA) and enzyme-linked immunosorbent assay (ELISA).
Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titers (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicited by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in 8 of 12 common serotypes according to predefined response criteria) was higher in PCV13 recipients than in PPSV23 recipients after one month (40% *vs* 22%, p=0.034) as well as after six months (33% *vs* 17%, p=0.041). Never did PPSV23 trigger a better immune response for any of the serotypes, than PCV13, regardless of analysis. For two of the serotypes, OPA GMTs were lower at the six months than at the one-month follow up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.
Summary/Conclusions: In patients with previously untreated CLL, the efficacy of PCV13 in terms of immune response is superior to PPSV23 for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against *Streptococcus pneumoniae* for these patients and administered as early as possible during the course of the disease.

S806

INFECTION-RELATED MORTALITY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: AGE, CMV AND PRE-TRANSPLANT LEVELS OF IGA/IGM PREDICT IRM IN A NEW CLINICO-BIOLOGICAL SCORING SYSTEM

A. Forcina[1,*], P. Rancoita[2], V. Marasco[1], R. Greco[1], M.T. Lupo Stanghellini[1], M. Carrabba[1], M. Marcatti[1], C. Di Serio[2], M. Bernardi[1], J. Peccatori[1], C. Corti[1], A. Bondanza[1], F. Ciceri[1]
[1]IRCCS San Raffaele Scientific Institute, [2]Vita-Salute San Raffaele University, Milan, Italy

Background: Infection-related mortality (IRM) is a major challenge after allogeneic hematopoietic stem cell transplantation (allo-HSCT).
Aims: The aim of this study was to develop a scoring system predicting IRM based exclusively on pre-transplant data.
Methods: A total of 589 adult patients receiving allo-HSCT were studied (Jan 2009 - Nov 2016). In a training set of patients (n=273, Jan 2012-May 2015) the ROC curve analysis defined the optimal cut-offs predicting 100-day IRM for continuous data. All clinical and biochemical variables were challenged in a multivariate analysis and a 3-tiered weighted score was elaborated and tested firstly in a retrospective validation set (n=219, Jan 2009-Dec 2011) and then in a prospective validation set (n=97, Jun 2016-Nov 2016).
Results: Median follow-up was 43 months (range 1-85). Acute leukemia was the main indication to transplant, accounting for 60% (n=356) of patients. The majority of the patients received an alternative-donor transplant (44% a HLA-haploidentical, 37% a matched unrelated donor). Forty-seven percent (n=277) of patients had advanced diseases. Multivariate analysis revealed age >60 yrs (P=0.003), CMV host/donor serostatus different from negative/negative (P<0.001) and pre-transplant levels of IgA <1.11 g/L (P=0.004) and IgM <0.305 g/L (P=0.028) as the only independent predictors of increased IRM. Noticeably, these associations were independent from disease type or status, donor type, intensity of conditioning, *in vivo* T or B-cell depletion or from previous colonization by multidrug-resistant bacteria. According to the proposed IRM score, patients were divided into 3 classes: low (<10.17 points), intermediate (10.17-11.11 points) or high-risk (>11.11 points). In the training set, 100-day and 2-yrs IRM were 5% (95% CI 2-10) and 9% (95% CI 4-16) for low-risk, 11% (95% CI 5-18) and 23% (95% CI 14-33) for intermediate-risk, and 16% (95% CI 16-37) and 41% (95% CI 28-53) for high-risk patients, respectively (P=0.001). In the retrospective validation set, 100-day and 2-yrs IRM were 7% (95% CI 3-14) and 14% (95% CI 8-22) for low-risk, 17% (95% CI 10-26) and 23% (95% CI 15-33) for intermediate, and 28% (95% CI 15-42) and 33% (95% CI 19-4) for high-risk patients, respectively (P= 0.044), with a c-index of 0.608 (Figure 1). In the prospective validation set, only 100-day IRM was calculated due to a shorter follow-up, being of 0%, 3% (95% CI 0-13) and of 14% (95% CI 3-33) for low, intermediate and high-risk patients (P=0.003). Additionally, in both training and retrospective validation sets (n=492), the 2-yrs OS was different among the 3 groups, being 59% (95%CI 52-67), 50% (95%CI 43-59) and 37% (95%CI 29-48) for low, intermediate and high-risk groups, respectively (P=0.0001). In the prospective validation set, only 100-day OS was evaluated, being of 95% (95%CI 88-100), 91% (95%CI 82-100) and 80% (95%CI 65-100), respectively (P=0.03). Out of a total of 129 infection-related deaths, 94/129 (73%) were attributed to bacteria, 22/129 (17%) to viruses, 11/129 (8%) to fungi and 2/129 8 (2%) to parasites.

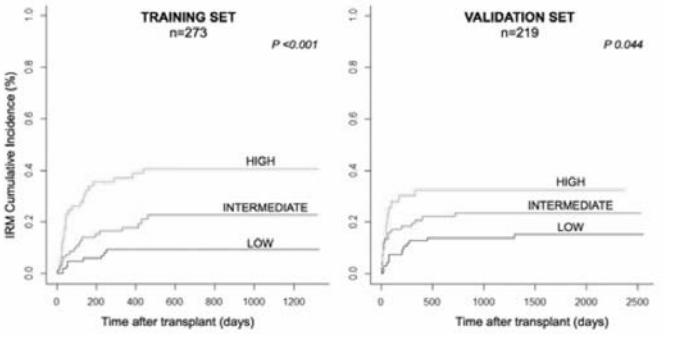

Figure 1.

Summary/Conclusions: This new clinic-biological score based on age, CMV serostatus and levels of IgA and IgM, may contribute to the prompt identification of patients at higher risk of fatal infections prior to allo-HSCT, thus promoting post-transplant personalized intensive active surveillance strategies and immune-intervention approaches to improve the overall outcome of transplant. A multicentric Italian study in currently on the way for the external validation of these results

Background: CMV remains a common complication of HCT, yet no antiviral drug suitable for prophylaxis is available in HCT. LET is a first-in-class drug

that inhibits the CMV terminase complex. A dose-escalation phase 2 trial showed that LET prophylaxis for up to 12 weeks post-HCT was effective with a safety profile similar to placebo.

Aims: To compare LET prophylaxis to placebo for the prevention of clinically significant CMV infection (CS-CMV), defined as CMV disease or CMV viremia leading to preemptive treatment (PET) in a Phase III randomized, double-blind, placebo-controlled trial.

Methods: CMV seropositive HCT recipients 18 years or older who had undetectable plasma CMV DNA within 5 days of randomization were eligible (full eligibility at clinicaltrials.gov, NCT02137772). Subjects had to start treatment by Day+28 post-HCT. Subjects were randomized 2:1 to receive LET or placebo PO or IV through Week 14 (Day +100) post-HCT, stratified by study site and high or low CMV disease risk. LET was dosed at 480 mg/d (or 240 mg/d if on cyclosporine due to drug-drug interaction). Subjects were assessed weekly through Week 14, biweekly through Week 24, and every other month through Week 48 after HCT. Plasma obtained at each visit was assayed for CMV DNA in a central laboratory. Subjects who developed CS-CMV discontinued study drug and received anti- CMV treatment. Local CMV assay results could be used to start PET. The primary endpoint was the stratum-adjusted proportion of subjects with CS-CMV through Week 24 post-HCT among subjects with undetectable CMV DNA at randomization; subjects who discontinued the study for any reason or with missing data at Week 24 were considered failures. All adverse events (AEs) were analyzed through 14 days after the last dose of study drug.

Results: From June 2014 to March 2016, 565 randomized subjects received study treatment; 31% were at high CMV disease risk. 50% subjects received myeloablative conditioning, 35% received ATG. Donors included 14% mismatched unrelated, 13% haploidentical and 4% cord blood. Study arms were balanced. Subjects began study drug a median of 9 days post-HCT; 37% had engrafted prior to start. Of 495 treated subjects with undetectable CMV DNA at randomization, fewer subjects developed CS-CMV or were considered failures in the LET arm (122/325, 38%) compared to placebo (103/170, 61%; p<0.0001) by Week 24 post-HCT. Figure 1 shows the time to CS-CMV analysis. The most common AEs (LET, placebo) were GVHD (39%, 39%), diarrhea (26%, 25%), and nausea (27%, 23%). More frequent vomiting (19%, 14%), edema (15%, 9%), atrial arrhythmias (10%, 5%), and ALT levels >5xULN (4%, 2%) was noted in LET-treated subjects; no increased myelotoxicity or nephrotoxicity was observed. The Week 24 all-cause mortality was 10% for LET recipients and 15% for placebo recipients.

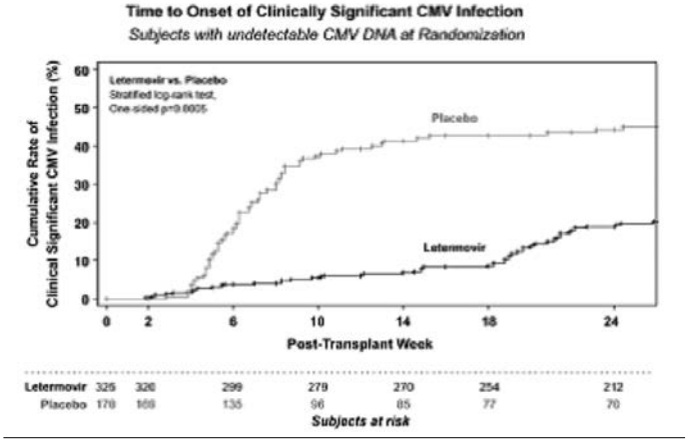

Figure 1.

Summary/Conclusions: Letermovir prophylaxis was effective in reducing clinically significant CMV infection, was overall well tolerated, and provides a new approach to CMV prevention after HCT.

S808

EFFICACY AND SAFETY OF DEFIBROTIDE TO TREAT HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME POST-CHEMOTHERAPY: A POST HOC ANALYSIS OF FINAL DATA OF AN EXPANDED-ACCESS PROTOCOL

N. Kernan[1], P. Richardson[2,*], S. Grupp[3], J. Antin[4], Y. Messinger[5], W. Liang[6], R. Ryan[6], R. Hume[6], W. Tappe[6], R. Soiffer[7]

[1]Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, [2]Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, [3]Pediatric Oncology, The Children's Hospital of Philadelphia, Philadelphia, [4]Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, [5]Children's Hospitals and Clinics of Minnesota, Minneapolis, [6]Jazz Pharmaceuticals, Inc., Palo Alto, [7]Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT), and VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States. However, VOD/SOS can occur after chemotherapy without HSCT.

Aims: To perform a *post hoc* analysis of final data on safety and response to defibrotide in patients developing VOD/SOS after primary chemotherapy without HSCT (off label).

Methods: In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25 mg/kg/d (4 divided doses of 6.25 mg/kg) was given a recommended ≥21 days after patients provided informed consent. Post-chemotherapy subgroup survival was analyzed *post hoc* from the day defibrotide was started (days 0–30 after start of chemotherapy) for 70 days (because follow-up data were collected for 100 days post-chemotherapy).

Results: Of 1154 VOD/SOS patients receiving defibrotide, 137 (12%) developed VOD/SOS post-chemotherapy without HSCT. Among the 82 patients (38 with MOD) treated with DF by day 30 after start of chemotherapy, median age was 7.5 years (range, 0–68 years) and 66 (81%) were pediatric patients (≤16 years of age). Among pediatric patients, 15% were age 0-23 months, 74% were 2-11 years and 11% were 12-16 years. Most common primary diseases were acute lymphocytic leukemia (51%), acute myeloid leukemia (13%), and neuroblastoma (6%). Kaplan-Meier estimated survival at Day +70 was 74% overall (95% CI, 63–82%); 66% (49–79%) in patients with MOD and 81% (66–90%) in patients without MOD. By age subgroup, Kaplan-Meier estimated survival at Day +70 was 80% (95% CI, 68–88%) in pediatric patients (Figure 1) and 50% (95% CI, 25–71%) in adults. Adverse events (AEs) were reported in 54/82 patients (66%). Hemorrhagic AEs (≥2%) were pulmonary (6%), epistaxis or mouth (4%), and hematochezia (2%). There were 22 (27%) patients with AEs assessed as being at least possibly related to defibrotide, the most common (≥2%) were pulmonary or mouth hemorrhage (4% each) and hematochezia, nausea, encephalopathy, epistaxis, or hypotension (2% each). Related AEs led to discontinuation in 6 patients and were associated with 1 death (pulmonary hemorrhage, hypotension).

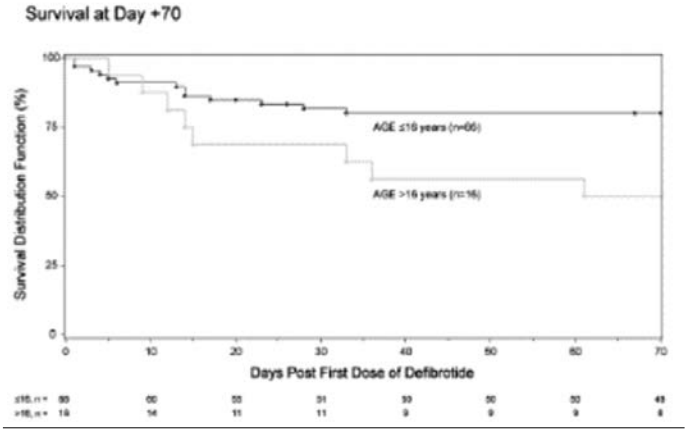

Figure 1.

Summary/Conclusions: The 74% survival rate at Day +70 in patients with VOD/SOS receiving defibrotide within 30 days of starting chemotherapy (81% in patients ≤16 years) is clinically encouraging. Of note is the 66% survival rate in patients with MOD. The defibrotide safety profile was consistent with that previously reported in the overall population of this expanded-access protocol.

Support: Jazz Pharmaceuticals.

Iron: Deficiency and overload

[1]MMPU - Molecular Medicine Partnership Unit, [2]Department of Pediatric Hematology, Oncology and Immunology, University of Heidelberg, Heidelberg, [3]Institute of Experimental Cancer Research, University Hospital Ulm, Ulm, [4]Institute of Clinical Molecular Biology and Tumor Genetics, Helmholtz Zentrum München, [5]Institute for Stroke and Dementia Research, Klinikum der Universität München, Munich, Germany, [6]Department of Biosystems Science and Engineering, Swiss Federal Institute of Technology in Zurich, Basel, Switzerland, [7]Institute for Tumor Biology and Experimental Therapy, Georg-Speyer-Haus, Frankfurt, [8]Research Unit Analytical Pathology, [9]Institute of Molecular Immunology, [10]Institute of Experimental Genetics, [11]Institute of Developmental Genetics, Helmholtz Zentrum München, Munich, Germany

Background: GPX4 is a selenoprotein belonging to the family of the glutathione peroxidases, a class of enzymes involved in cellular defence against oxidative stress. This enzyme is essential for life since it is the only peroxidase able to use lipid peroxides as substrate. Mice constitutively lacking GPX4 die at embryonic stage while tissue-specific ablation in neurons and T-cells cause neurodegeneration and impaired immune response. Recent studies have identified GPX4 as the main regulator of ferroptosis, an iron-dependent ROS-mediated form of nonapoptotic cell death. Erythrocytes are highly specialized cells that utilize a large amount of iron to bind and deliver oxygen to all tissues. Being constantly exposed to oxygen, erythroid cells need to continuously fight against oxidative stress by expressing a variety of antioxidant enzymes, including GPX4. Iron availability for erythropoiesis depends on systemic iron levels which are regulated via the hepcidin/ferroportin regulatory system. Hepcidin binding to the iron exporter ferroportin reduces systemic iron export regulating body iron levels. In hypoxic conditions the erythroid hormone ErFe suppresses hepcidin synthesis to provide iron for the elevated erythropoietic demand.
Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis.
Methods: Lethally irradiated C57BL/6 female mice were reconstituted with bone marrow cells from $Gpx4^{fl/fl}$; $Rosa26\text{-}Cre^{ERT2}$ or $Gpx4^{wt/wt}$; $Rosa26\text{-}Cre^{ERT2}$ and allowed to recover for 8 to 10 weeks. Gpx4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were drawn at 3 and 6 weeks after terminating the tamoxifen-containing diet. Erythroid cells have been analysed in FACS. Serum iron levels have been assessed using the SFBC and UIBC iron kits (Biolabo). Gene expression analysis has been performed using SYBR-green qRT-PCR. Circulating Hepcidin has been measured with a specific murine ELISA kit (Intrinsic Lifesciences). Tissue iron levels have been measured with a colorimetric assay. All animal experiments were approved by and conducted in compliance with institutional guidelines
Results: Compared to $GPX4^{wt/wt}$;Cre^{ERT2} controls, $GPX4^{fl/fl}$;Cre^{ERT2} transplanted mice lacking GPX4 in the haematological compartment show a decrease in the number of red blood cells, haemoglobin and haematocrit. Reticulocyte count measurement revealed a strong increase in this population, suggesting that the erythropenia could be due to a block in the reticulocyte maturation. Reticulocyte FACS characterization revealed a shift towards a more immature population while electron microscopy analysis showed an accumulation of unphagocytosed vesicles containing remnants of mitochondria. Analysis of the spleen revealed extramedullary erythropoiesis. The anemia and the erythropenia trigger a hypoxic signature hallmarked by an increase in circulating EPO and increased ErFe expression. However, both hepatic mRNA analysis and circulating protein measurement failed to show alteration in hepcidin production. Analysis of the liver showed an increase in non-heme iron content and in the lipid peroxidation causing an elevated mRNA and protein expression of heme oxygenase 1. Hepatic ferritin and ferroportin are also increased as a consequence of the increased iron content.
Summary/Conclusions: Our data show for the first time that the presence of GPX4 in the haematological compartment is essential for the proper hepcidin downregulation upon ErFe stimulation. This finding opens new insights in the mechanism that regulate hepcidin during hypoxia.

S810

IDENTIFICATION OF GUANOSINE 5'-DIPHOSPHATE AS POTENTIAL IRON MOBILIZER: PREVENTING THE HEPCIDIN-FERROPORTIN INTERACTION AND MODULATING THE INTERLEUKIN-6/STAT-3 PATHWAY

S. Angmo[1,*], N.K Singhal[2]
[1]Food science and Nanobioscience, [2]National Agri Food biotechnology, Mohali, India

Background: Anemia of inflammation (AI) is one of the most common manifestations of iron deficiency in the patients with inflammatory conditions. AI is responsible for hypoferremia, with consequent iron-restricted erythropoiesis with high level of hepcidin, which stimulate the internalization of ferroportin (FPN) transporter. Therefore, inhibiting hepcidin-mediated FPN degradation can be an important strategy to ameliorate AI.
Aims: To increase iron bioavaibility we selected a Novel compound against hepcidin action through natural compound libraries that might provide a new alternative approach to increase iron absorption for prevention of hepcidin-mediated FPN internalization and to ameliorate turpentine-induced anemic state with different *insilico, invitro and invivo* studies.
Methods: A systematic approach involving *in silico*, *in vitro* and *in vivo* studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFP-FPN, Caco-2, HepG2) using flow cytometry and western blotting. Normal or turpentine induced anemic mice were used in the associated studies.
Results: The virtual screening via molecular modelling showed that GDP as a potent hepcidin-binding agent as shown in the (Figure 1A). *In vitro* studies revealed that GDP significantly increased ferroportin stabilization in GFP-FPN cell lines (Figure 1C) and *In vivo* results showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turpentine-induced anemic state with increase in haemoglobin level (Figure 1B).

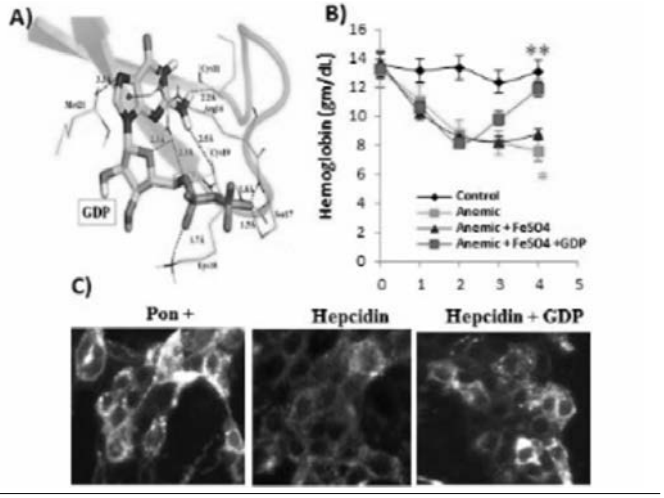

Figure 1.

Summary/Conclusions: AI is a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDP molecule have higher contribution to the stability of hepcidin-GDP complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDP along with iron supplement regime can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for AI.

S811

UNRAVELING THE MOLECULAR PATHOGENESIS OF INEFFECTIVE ERYTHROPOIESIS IN CONGENITAL DYSERYTHROPOIETIC ANEMIA TYPE II: *IN VITRO* EVALUATION OF RAP-011 TREATMENT

G. De Rosa[1,*], I. Andolfo[1], F. Manna[1], A. Gambale[1], R. Marra[1], B. E. Rosato[1], A. Iolascon[1], R. Russo[1]
[1]Molecular Medicine and Medical Biotechnology, CEINGE - Biotecnologie Avanzate, Naples, Italy

Background: Congenital Dyserythropoietic Anemias (CDAs) are subtypes of bone marrow failure syndromes, hallmarked by ineffective erythropoiesis. The most common form is CDAtype II (CDAII), showing moderate/severe anemia, relative reticulocytopenia, jaundice, and iron overload. It is inherited as autosomal recessive disorderdue to loss-of-function mutations in*SEC23B* gene. More than 300 CDAII cases and 80 causative mutationshave been described so far. Despite this high allelic heterogeneity, two variants, R14W and E109K, represent more than 50% of the mutational events. To date, treatments for CDAII patients consist of supportive therapy, such as erythrocyte transfusions, or bone marrow transplantation or splenectomy in transfusion-dependentcases.Recently, members of TGF-β superfamily have been studied as potential regulators of erythropoiesis,especially the growth differentiation factor 11 (GDF11). Through the binding of specific receptors, GDF11 leads to an inhibited late-stage erythropoiesis. Indeed, two GDF11 inhibitors, ACE-011 and ACE-536,have been associated to an improvement of hematologic parameters. Studies with the mouse counterpart of ACE-011, RAP-011, on mouse model of β-thalassemia showed increased differentiation of erythroid cells, improvement of anemic condition and reduced iron overload in treated mice.

Aims: The main aim of our study is to assess the effects of RAP-011 on different cellular models of CDAII.
Methods: We measured circulating GDF11 levels in CDAII patients and healthy controls(HC) bywestern blot(WB). To assess the effectiveness of RAP-011(provided by Celgene Corporation)*in vitro*, we established two different cellular models of CDAII: (i) K562 cells stably silencedfor *SEC23B* by Sh-RNA carried in GIPZ lentiviral vectors; (ii) K562 stably overexpressing SEC23B-WT and the two variants, R14W and E109K. *In vitro* treatment has been performed at 0, 3, and 6 days of erythroid differentiation by hemin+GDF11 in presence or absence of RAP-011 in K562 cells stably silencedfor *SEC23B*.
Results: WB and subsequent densitometric analysis showed an increase of GDF11 levels in serum samples from 18 CDAII patients compared to 18 HC (p=0.02). Stable silencing of *SEC23B* in K562 cellsled to the establishment of two different clones, Sh-70 and Sh-74, showing amarkedreduction of SEC23Bexpression compared to Sh-CTR (85-90% and 60-65%, respectively). At 3 and 6 days of K562 erythroid differentiation by hemin, we observed an increased expression of pSMAD2 in GDF11-treated cells compared to non-treated ones; interestingly, a reduction of pSMAD2 in RAP-011+GDF11-treated cells was observed.
Summary/Conclusions: We firstly demonstrated the increased levels of GDF11 in CDAII patients. Thus, we used a combined treatment with hemin+GDF11 in SEC23B-silenced K562 stable clones, in order to reproducethe pathologic phenotype of the disease, andto make K562 cells suitable for RAP-011 treatment, as attested by the increased expression of pSMAD2 in GDF11-treated cells. The reduced pSMAD2 in RAP-011+GDF11-treated cells suggests that RAP-011treatment leads to repression of ActRIIA/B pathway, which in turn should increase nuclear levels of GATA1 transcription factor. This action should lead to an increased expression of GATA1-activated genes involved in erythroid development. The evaluation of GATA1 activation is ongoing, as well as the *in vitro* treatment of K562 stably overexpressing SEC23B-WT,SEC23B-R14W and -E109K.

S812

INTRAVENOUS IRON *VERSUS* ORAL IRON *VERSUS* NO IRON WITH OR WITHOUT ERYTHROPOIESISSTIMULATING AGENTS FOR CANCER PATIENTS WITH ANAEMIA: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

A. Weigl[1,*], N. Köhler[1], I. Monsef[1], J. Bohlius[2], I. Becker[3], K. Kuhr[3], N. Skoetz[1]
[1]Cochrane Haematological Malignancies, University Hospital Cologne, Cologne, Germany, [2]Institute of Social and Preventive Medicine, University Bern, Bern, Switzerland, [3]Institute of Medical Statistics, Informatics and Epidemiology, University Hospital Cologne, Cologne, Germany

Background: A widely prevalent complication in patients suffering from cancer is the deficiency of haemoglobin-containing red blood cells, referred to as anaemia. While many patients develop anaemia due to an involvement of malignant bone marrow cells, others suffer from so called chemotherapy/radiotherapy-induced anemia. Erythropoiesis-stimulating agents (ESAs) stimulate the production of red blood cells within the bone marrow and have shown to increase Hb levels in anaemic patients. Uncertainties remain regarding the effect of iron supplementation on the fatal consequences of ESA-treatment.
Aims: The aims of this systematic review and network meta-analysis are to evaluate benefits and risks of ESAs and iron for the treatment of disease-related as well as therapy induced anaemia in cancer patients.
Methods: Based on an a-priori Cochrane protocol, we developed sensitive search strategies for Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, databases of ongoing trials and conference proceedings (search date 12/2016). We included only randomized controlled trials (RCTs) including anaemic patients of any age with solid and/or haematological malignancy undergoing chemotherapy, radiotherapy or no anti-cancer therapy. We excluded studies including anaemic cancer-patients as a result of surgery or due to haemolysis. Two authors independently assessed studies for eligibility, extracted data and assessed quality of trials. The primary outcome was on-study mortality. Secondary outcomes included number of red blood cell transfusions and thromboembolic events. For binary outcomes, we used risk ratios (RRs) with corresponding 95% confidence intervals (CIs) to evaluate the treatment effects. We performed a random-effects meta-analysis for direct comparisons. For network meta-analyses, we used the frequentist graph-theoretical approach. Treatment hierarchy was obtained giving P-scores on a scale from 0 (worst) to 1 (best).
Results: We identified a total number of 105 eligible studies, including 25.722 patients. The network analysis of the primary outcome, on-study mortality, included 69 studies and 8 treatments. As the given network was not fully connected, we performed pairwise comparisons on the four subnetworks with 2 treatments each. Statistically significant treatment disadvantages were shown in the direct comparison of ESA plus iron supplementation (given if necessary) compared to placebo/no treatment plus iron supplementation (given if necessary) (RR 1.14 (95% CI 1.03-1.25), including 41 studies). Network meta-analysis on the need for red blood cell (RBC) transfusions showed the treatment of ESA plus iron supplementation to have the most positive effect compared to ESA alone (RR: 0.70 (95% CI 0.53-0.92) P-score: 0.87). No relevant heterogeneity was found within the analysed network of four treatments (I^2=18.4%). Inconsistency could not be tested statistically as no closed loop was included. Thromboembolic events occurred most often in patients treated with ESAs, irrespective of iron supplementation (ESA plus iron *vs* no treatment/placebo plus no iron: RR 1.79 (95% CI 0.74-4.32) P-score: 0.22, ESA plus no iron *vs* no treatment/placebo plus no iron: RR 1.90 (95% CI 0.96-3.75) P-score: 0.16). Subgroup analysis regarding type of iron, as well as route of administration will be presented at the EHA-congress (Figure 1).

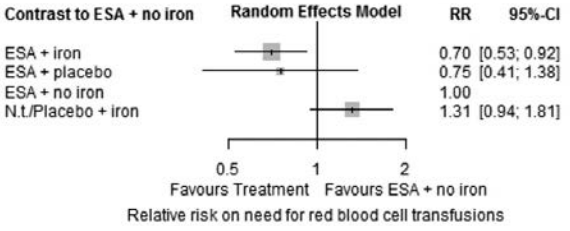

Figure 1.

Summary/Conclusions: While our analyses show that ESA use increases mortality and risk for thromboembolic events, there is no evidence that iron supplementation alters these risks. However, addition of iron to ESA does further decrease the need for RBC-transfusions compared to ESA alone. Further investigation, with regards to iron type and route of administration may yield further distinct results.

DIFFERENT IRON SOURCES AND ACQUISITION PATHWAYS SHAPE MACROPHAGES TOWARDS OPPOSING FUNCTIONAL PHENOTYPES

F. Vinchi[1,*], R. Sparla[1], E. Tolosano[2], U. Platzbecker[3], M.U. Muckenthaler[1]
[1]Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, [2]Molecular Biotechnology Center, University of Turin, Turin, Italy, [3]University Clinic Dresden, Dresden, Germany

Background: Iron homeostasis and macrophage biology are closely interconnected. On the one hand, reticulo-endothelial macrophages are central for the regulation of iron homeostasis. The phagocytosis and degradation of senescent red blood cells (RBC) by macrophages enable efficient recycling of iron and the maintenance of systemic iron balance. On the other hand, iron exerts multiple effects on macrophage polarization and functionality. Macrophages exhibit a remarkable functional plasticity, reflected in their capacity to integrate diverse signals from the microenvironment and acquire distinct phenotypes. Macrophage polarization has been shown to dictate the expression of iron-regulated genes and determine cell iron handling.
Aims: Increasing evidence shows that iron availability itself has significant effects on immune effector functions and macrophage polarization. However, it is still unclear how different iron sources and acquisition pathways affect macrophage phenotypes.
Methods: To investigate this aspect, we analyzed both *in vivo* and *in vitro*, and compared the phenotypic switching of macrophages induced by different iron sources, including heme and iron, as well as hemolytic or intact RBCs.
Results: Hemolytic RBCs, free heme and iron-dextran treatment in mice shape macrophage polarization towards an M1-like pro-inflammatory phenotype. Splenic and hepatic macrophages from treated mice show iron deposition and increased expression of iron-related genes (ferroportin, ferritin, HO-1). Moreover, in these cells, the expression of M1 markers such as MHCII, CD86 and pro-inflammatory cytokines (TNFa, IL-6, IL-1b) is strongly increased, whereas the expression of M2 markers such as CD206, Arg-1 and IL-10 was significantly suppressed. Consistent results have been obtained treating bone marrow-derived macrophages with hemolytic RBCs, free heme and Fe-NTA. Importantly, the addition of the heme scavenger hemopexin and the iron carrier transferrin or the chelator deferoxamine fully abolish the ability of free heme and iron to trigger M1 polarization. On the contrary, RBC transfusions in mice shape macrophages towards an M2-like anti-inflammatory phenotype. After three transfusions, serum iron and hepcidin levels significantly rise, and tissues as well as macrophages are heavily iron loaded. Macrophages show a drastic suppression of M1 markers and inflammatory cytokines, and induction of M2 markers. Interestingly, repeated transfusions result in extensive macrophage cell death and new monocytes recruitment in both liver and spleen.
Summary/Conclusions: Collectively, these results suggest that the source and route of iron acquisition have a key role in shaping macrophage phenotype, and demonstrate a dynamic role of iron overload in determining macrophage polarization and function. When iron is provided in the form of free heme or non-transferrin bound iron, it exerts a clear pro-inflammatory effect on macrophages; whereas when provided via a controlled physiological acquisition pathway such as erythrophagocytosis, it dampens macrophage immune effector functions, being its clearance activity more active.

Our findings have potential implications, on one side, for hemolytic diseases, where RBC hemolysis and elevated circulating heme might promote a detrimental chronic inflammatory state, and, on the other one, for infectious diseases, where free heme and iron, released upon cell damage, might boost inflammation and enhance resistance to infections. Conversely, accelerated RBC clearance, by suppressing macrophage pro-inflammatory response, is rather expected to promote infections in transfused individuals.

A PHASE 3 STUDY TO EVALUATE SAFETY AND EFFICACY OF LENTIGLOBIN GENE THERAPY FOR TRANSFUSION-DEPENDENT B-THALASSEMIA IN PATIENTS WITH NON-B0/B0 GENOTYPES: THE NORTHSTAR-2 (HGB-207) TRIAL

M. Walters[1,*], A. Thompson[2], S. Hongeng[3], J. Kwiatkowski[4], F. Locatelli[5], J. Porter[6], M. Sauer[7], A. Thrasher[8], I. Thuret[9], E. Yannaki[10], A. Petrusich[11], M. Asmal[11]

[1]UCSF Benioff Children's Hospital and Research Center, Oakland, [2]Lurie Children's Hospital , Chicago, United States, [3]Ramathibodi Hospital, Bangkok, Thailand, [4]Children's Hospital of Philadelphia , Philadelphia, United States, [5]IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, [6]University College London Hospital, London, United Kingdom, [7]Medizinische Hochschule Hannover , Hannover , Germany, [8]Great Ormond Street Hospital, London, United Kingdom, [9]Hôpital d'enfants de La Timone, Marseille, France, [10]General Hospital of Thessaloniki, Thessaloniki, Greece, [11]bluebird bio, Cambridge, United States

Background: Standard treatment for transfusion-dependent β-thalassemia (TDT) includes regular red blood cell (RBC) transfusions and management of iron overload. Successful allogeneic hematopoietic cell transplantation (HCT) can eliminate RBC transfusions and, eventually, chelation. However, due to transplant-related risks such as graft-*versus*-host disease (GVHD), as well as donor constraints, HCT is rarely an option for TDT patients. By transferring a functioning copy of the β-globin (*HBB*) gene into hematopoietic stem cells (CD34+ cells) and re-infusing the modified cells, gene therapy may be an alternative one-time treatment available to all patients with TDT, without risks of GVHD. LentiGlobin gene therapy is an investigational treatment consisting of autologous CD34+ cells transduced with the BB305 lentiviral vector. The Northstar (HGB-204) phase 1/2 clinical study of LentiGlobin gene therapy for TDT included 18 patients who received LentiGlobin drug product (DP). As of September 2016, all patients in Northstar with non-β^0/β^0 genotypes and at least 12 months of follow-up stopped transfusions (median total hemoglobin [Hb] 11.2 [range 9.4−12.2] g/dL) and there was >60% reduction in transfusions in patients with a β^0/β^0 genotype. The safety profile was consistent with autologous HCT. In this initial study, the average number of therapeutic gene copies per CD34+ cell in the DP (*i.e.* DP vector copy number per diploid genome or DP VCN; median 0.7, range 0.3 to 1.5) correlated with peripheral HbA^{T87Q} (genetically engineered hemoglobin) expression at 6 months (ASH, 2016). In an effort to optimize the proportion of patients able to discontinue blood transfusions to achieve "transfusion independence" in all patients and increase unsupported Hb levels after treatment, the manufacturing process for LentiGlobin DP was modified to increase the DP VCN and the proportion of genetically modified cells. Northstar-2 (HGB-207) is a recently initiated phase 3 study using this new manufacturing process in patients with TDT and a non-β^0/β^0 genotype.

Aims: To evaluate safety and efficacy of autologous HCT with LentiGlobin DP in patients with TDT and a non-β^0/β^0 genotype.

Methods: After providing informed consent, patients 12 to 50 years of age (N=15) will have CD34+ cells collected via mobilization and apheresis. After individualized DP manufacture and satisfaction of release criteria, the patient will receive myeloablative conditioning with single-agent busulfan (starting dose 3.2 mg/kg/day for 4 days, with target AUC 4500 [range 4000−5000] μM*min) followed by infusion of LentiGlobin DP. Patients will be followed for engraftment, safety and efficacy endpoints for 2 years after infusion; patients will then have the option to enroll in a 13-year follow-up study. The primary endpoint is the proportion of patients who achieve transfusion independence after DP infusion, defined as total Hb ≥9g/dL without RBC transfusions for a continuous period of ≥12 months. Secondary endpoints include time to neutrophil engraftment, adverse events, and biological parameters including VCN in peripheral blood and levels of HbA^{T87Q} over time.

Results: As of March 1, 2017, two 20-year-old females with β^0/β^E genotypes have been treated with LentiGlobin DP in the Northstar-2 trial. The DP VCN was 2.9 and 2.4 copies per diploid genome, respectively. Outcomes in all evaluable patients will be presented.

Summary/Conclusions: Results from the Northstar-2 study will provide data on safety and demonstrate the extent to which an increase in LentiGlobin DP VCN yields normalization of total Hb and consistently achieves transfusion independence in patients with TDT of non-β^0/β^0 genotypes. Optimizing DP VCN has the potential to improve outcomes across all TDT genotypes treated by investigational LentiGlobin gene therapy.

S815

CIS IS A POTENT CHECKPOINT IN NK CELL ANTI-LEUKEMIA IMMUNITY

N. Huntington[1,*]

[1]Molecular Immunology, Walter and Eliza Hall, Parkville, Australia

Background: The detection of leukemia by natural killer (NK) cells is controlled

by the integration of signals from activating and inhibitory ligands and from cytokines such as IL-15.
Aims: We set out to identify the negative regultors of NK cell function in order to understand why immunogenic tumours and leukemia can evade or overcome NK cell detection and killing.
Methods: We used a multidisciplinary approach including RNAseq, Mass Spectrometry, Structual biology, kinase enrichment and activity assays, NK cell *in vitro* analysis, biochemistry and de novo/experimental tumor/leukemia *in vivo* models.
Results: We identified cytokine-inducible SH2-containing protein (CIS, encoded by *Cish*) as a critical negative regulator of IL-15 signaling in NK cells. *Cish* was rapidly induced in response to IL-15, and deletion of *Cish* rendered NK cells hypersensitive to IL-15, as evidenced by enhanced proliferation, survival, IFN-gamma production and cytotoxicity toward tumors. This was associated with increased JAK-STAT signaling in NK cells in which *Cish* was deleted. Correspondingly, CIS interacted with the tyrosine kinase JAK1, inhibiting its enzymatic activity and targeting JAK for proteasomal degradation. *Cish*−/− mice are resistant to leukemia *in vivo*, and this was independent of MHC-I expression.
Summary/Conclusions: Our data uncover a potent intracellular checkpoint in NK cell–mediated tumor immunity and suggest possibilities for new cancer immunotherapies directed at blocking CIS function.

S816

GENERATION OF MEMORY STEM T CELLS MODIFIED WITH A NOVEL OPTIMIZED CD30-SPECIFIC CHIMERIC ANTIGEN RECEPTOR FOR THE TREATMENT OF CD30+ T-CELL MALIGNANCIES

L. Escribà-Garcia[1,*], C. Alvarez-Fernández[1], J. Wegner[2], J. Rydzek[2], M. Tellez-Gabriel[1], J. Sierra[1], H. Einsele[2], J. Briones[1], M. Hudecek[2]
[1]Hematology Service, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [2]Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany

Background: Peripheral T-cell lymphomas (PTCL) represent the most aggressive form among non-Hodgkin lymphomas with a very poor prognosis (5-year survival of 30%), demanding innovative novel treatment strategies. Adoptive immunotherapy with chimeric antigen receptor (CAR) engineered T cells has demonstrated its therapeutic potential in advanced hematological malignancies. However, its application to PTCL remains a formidable challenge mainly due to a lack of truly tumor-specific antigens that are not expressed on normal T cells. Anaplastic large T-cell lymphomas (ALCL) and several other subtypes of PTCL express CD30, which is expressed by activated normal T cells but no other healthy tissues. Indeed, brentuximab vedotin, an anti-CD30 antibody-drug conjugate, has shown some clinical efficacy in PTCL and ALCL patients although duration of responses is short in the majority of cases. Here, we developed a refined CD30-CAR T-cell approach to target CD30$^+$ PTCL as a potential novel therapeutic strategy. We selected a novel targeting domain that is unaffected by soluble CD30 protein to prevent blockade of the CD30-CAR *in vivo*. Moreover, we optimized the therapy by using memory stem T cells (T_{SCM}) to promote engraftment and persistence of CD30-CAR Tc ells after transfer, and we have included an EGFRt depletion marker as a safety feature.
Aims: We evaluated the antitumor effect of memory stem T cells (T_{SCM}) genetically-modified with a novel CD30-specific CAR that recognizes a membrane-proximal epitope in the CD30 molecule in a CD30$^+$ T-cell lymphoma model.
Methods: A second generation CD30-41BBz-EGFRt CAR was generated using a scFv that recognizes a tumor-cell membrane-proximal epitope of CD30 protein (Nagata S *et al*. Clin Cancer Res, 2002). Naive T cells from healthy donors were activated with anti-CD3/CD28 beads in presence of IL-7, IL-15 and IL-21 during 10 days to obtain a T_{SCM}-enriched population (Alvarez C *et al*. J Transl Med, 2016); on day 2 of culture, cells were transduced with a third-generation lentiviral vector encoding the CD30-CAR. The anaplastic large T-cell lymphoma cell line Karpas 299 was used as tumor model. Cytotoxicity assay was performed at 4 hours at 10:1, 5:1, 1:1 and 1:5 effector/target (E/T) ratios, and the tumor cell death was detected by flow citometry. Cytokines (IFN-γ and IL-2) were analysed at 24 hours in a 5:1 E/T ratio culture using Luminex technology.
Results: T_{SCM} were the most prevalent T-cell subset at day 10 of culture, representing 84 ± 3.1% of total cells, and the CD30-CAR expression in these cells was 76.9 ± 1.0% in CD4$^+$ T_{SCM} and 77.3 ± 2.0% in CD8$^+$ T_{SCM}. Although CD30 protein was detected in a fraction of activated T cells in culture (CD4$^+$ T cells: 32.4 ± 2.1%; CD8$^+$ T cells: 59 ± 4.3%), lentiviral transduction of T_{SCM} with our CD30-CAR did not compromise their *ex vivo* expansion (CD4$^+$ CD30-CAR T_{SCM}: 96.0 ± 3.2 fold expansion; CD8$^+$ CD30-CAR T_{SCM}: 109.0 ± 4.2 fold expansion). CD8$^+$ CD30-CAR T_{SCM} conferred specific cytolytic activity and lysed Karpas 299 cells *in vitro* (tumor cell death 1:1 ratio: 92.6 ± 2.4% *vs* 0% with untransduced T_{SCM}; p<0.001), while control CD30$^-$ target cells (Raji) were not recognized. In addition, CD30-CAR T_{SCM} secreted IFN-γ and IL-2 after stimulation with Karpas 299 cells (IFN-γ: 126.6 ± 18.12 pg/ml *vs* 5.03 ± 0.16 pg/ml with control targets, p=0.002; IL-2: 20.47 ± 2.3 pg/ml *vs* 4.06 ± 0.24 pg/ml, p=0.002, respectively).
Summary/Conclusions: Collectively, our data demonstrate the potential to generate CD30-CAR T cells with enhanced functional attributes against CD30$^+$ PTCL. T_{SCM} cells can be efficiently transduced and *ex vivo* expanded with a novel CD30-CAR and confer potent antitumor efficacy against CD30$^+$ PTCL *in vitro*. Our findings suggest the potential to improve outcome of patients with CD30$^+$ PTCL through adoptive therapy with CD30-CAR modified T cells.

MESENCHYMAL STROMAL CELLS FOR THE TREATMENT OF STEROID-RESISTANT ACUTE GRAFT *VERSUS* HOST DISEASE: FACTORS INFLUENCING CLINICAL RESPONSES

A. Galleu[1,*], S. Deplano[2], R. Szydlo[3], D. Milojkovic[2], A. Bradshaw[2], R. Wynn[4], D. Marks[5], D. Richardson[6], K. Orchard[6], E. Kanfer[2], E. Tholouli[4], M. Saif[4], P. Sivaprakasam[5], S. Lawson[7], A. Bloor[8], A. Pagliuca[9], J. Snowden[10], A. Vora[11], B. Kishore[12], H. Hunter[13], J. Apperley[2,3], F. Dazzi[3,14]
[1]Division of Cancer Studies, King's College London, [2]Imperial College Healthcare NHS Trust, [3]Imperial College London, London , [4]Central Manchester University Hospital, Manchester, [5]University Hospitals Bristol, Bristol, [6]University Hospital Southampton, Southampton, [7]Birmingham Women's and Children's Hospitals, Birmingham, [8]The Christie NHS Foundation Trust, Manchester, [9]King's College Hospital NHS Trust, London, [10]Royal Hallamshire Hospital, [11]Sheffield Children's Hospital, Sheffield, [12]Heart of England NHS Foundation Trust, Birmingham, [13]Plymouth Hospitals NHS Trust, Plymouth, [14]King's College London, London, United Kingdom

Background: The immunosuppressive activity of mesenchymal stromal sells (MSC) have been extensively tested for the treatment of steroid-resistant acute graft *versus* host disease (aGvHD). However, the factors affecting clinical responses are poorly understood.
Aims: We assessed the impact of MSC treatment on clinical outcomes and investigate factors influencing the response to MSC.
Methods: Data collected from a cohort of 60 patients treated with MSC between May 2008 and December 2014 in the UK were analyzed. Clinical grade MSC were generated from bone marrow aspirates collected from the iliac crest of healthy donors and expanded using platelet lysate. All patients received MSC for the treatment of steroid-resistant aGvHD, defined as failure to respond to high-dose steroids (2mg/Kg methyl-prednisolone) after 6 days. Informed consent was obtained from all patients in accordance with the local ethics committee requirements. Clinical responses to MSC were assessed 1 week after MSC infusion. Patients were defined as: a) Responders when an improvement of at least 50% in at least one organ affected by aGvHD was observed, or b) Non-Responders if they had stable or progressive disease.
Results: Patient characteristics are summarized in Table 1.

aGvHD was biopsy proven in 45 patients, while in the remaining patients the diagnosis was clinical and based on the exclusion of alternative causes. 10, 16 and 1 patients had skin, gut and liver involvement only, respectively. 16 patients exhibited gut and skin, 11 skin, gut and liver, 3 skin and liver and 3 gut and liver. 34 patients received 1 dose, while 19, 6 and 1 were treated with two, three and four doses, respectively. No side effects were observed. 36 patients (60%) responded to MSC. Amongst patients who received multiples doses (26), subsequent doses did not change the status after the first dose (24 responded, 1 did not respond), except from one patient who, although respond-

ing to the first dose, failed to respond to the second one. When we evaluated potential factors for response, organ involvement, age at transplant and the cumulative dose of MSC infused were found statistically significant. Response rate was 67% among patients with involvement of gut, skin or both, but only 22% among those with involvement of the liver (alone or in combination with skin and/or gut). Patients younger than 20 years fared better, with 88% of them responding. Conversely, only 30% and 42% of those aged 20-50 years or older than 50 responded, respectively. Lastly, higher cumulative MSC dose (>3.0x10^6/Kg) was associated with a response in 76%, while none of those receiving less than 1.5x10^6/Kg responded. All 3 factors remained significant in multivariate logistic regression analysis. Patient gender, pre-MSC therapy, interval from transplant or aGvHD diagnosis to MSC treatment and grade of aGvHD did not affect response. The impact of achieving a response 1 week after MSC had a profound impact on the overall survival at 18 months accounting for 59% in responders and 17% in non-responders (log-rank test, p<.001).
Summary/Conclusions: In our cohort of patients, MSC treatment was safe and well tolerated. We conclude that the presence of a response at one week highly impacted on the survival of patients with an otherwise very poor prognosis. Importantly, younger age at the transplant, absence of liver aGvHD involvement and use of higher MSC doses were strong predictors of a response.

S818

CARD9 CONTROLS DECTIN-1-INDUCED T-CELL CYTOTOXICITY AND TUMOR GROWTH IN MICE

T. Haas[1,*], S. Heidegger[1], H. Poeck[1], J. Ruland[2]
[1]Klinik und Poliklinik für Innere Medizin III, [2]Institut für Klinische Chemie und Pathobiochemie, Klinikum rechts der Isar, TU München, München, Germany

Background: Activation of the C-type lectin receptor Dectin-1 by beta-glucans triggers multiple signals within dendritic cells (DCs) that result in activation of innate immunity. While these mechanisms can potently prime $CD8^+$ cytotoxic T cell (CTL) responses without additional adjuvants, the Dectin-1 effector pathways that control CTL induction remain unclear.
Aims: Aims of this study were: To define details of the intracellular signalling pathway responsible for cross-priming of a CTL response after activation of the C-type lectin receptor Dectin-1. To analyze whether identified signalling molecules were indispensable for antitumor immunity. To analyze whether NK cells played a role in antitumor immunity after Dectin-1-mediated CTL induction.
Methods: We used *in vitro* coculture between DCs (wildtype *vs* gene deficient) and CD8 T cells to define signalling components of Dectin-1 induced CTL cross-priming. We used WT and gene-deficient mice to define the signalling pathway of Dectin-1 induced CTL crosspriming *in vivo* and to test the role of this pathway for antitumor immunity by challenging mice with B16-Ova tumor cells intravenously, with or without depletion of CD8 T cells or NK cells, respectively.
Results: Here we demonstrate that Dectin-1-induced CTL cross-priming in mice does not require inflammasome activation but strictly depends on the adapter protein Card9 *in vitro. In vivo,* Dectin-1-mediated Card9 activation after vaccination drives both expansion and activation of antigen-specific CTLs, resulting in long-lasting CTL responses which are sufficient to protect mice from tumor challenge. This Dectin-1-induced antitumor immune response was independent of natural killer (NK) cell function and completely abrogated in Card9-deficient mice. Thus, our results demonstrate that Dectin-1-triggered Card9 signaling but not inflammasome activation can potently cross-prime antigen specific CTLs, suggesting that this pathway would be a candidate for immunotherapy and vaccine development (Figure 1).

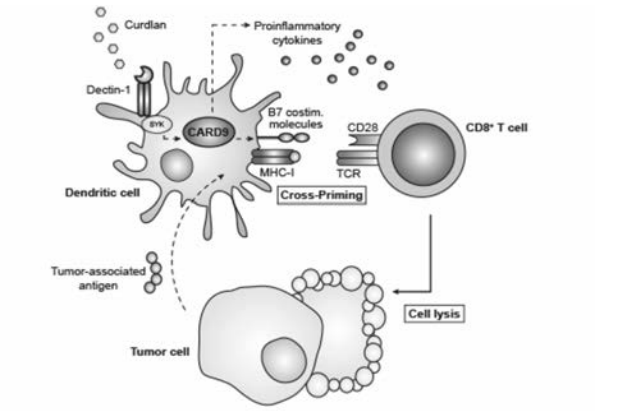

Figure 1.

Summary/Conclusions: We identify Card9 as central regulator of Dectin-1-induced cross-priming of cytotoxic T cells (CTLs) in mice. These antigen specific CTLs mediate potent antitumor immunity independent of inflammasome activity and NK cells. This pathway is a candidate for immunotherapy and vaccine development.

PRECLINICAL COMBINATION OF A NOVEL IRE1 RNASE INHIBITOR MKC-8866 AND TYROSINE KINASE INHIBITION ACTS SYNERGISTIC IN ACUTE LYMPHOBLASTIC LEUKEMIA

M. Vieri[1,*], A. Salimi[1], J.B. Patterson[2], A. Samali[3], E. Chevet[4], T.H. Brümmendorf[1], I. Appelmann[1], B. Kharabi[1]

[1]Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany, [2]MannKind Corporation, Valencia, United States, [3] Department of Biochemistry, National University of Ireland, Galway, Ireland, [4]Centre de Lutte Contre le Cancer Eugène Marquis, Université Rennes 1, Rennes, France

Background: The role of the Unfolded Protein Response (UPR) in BCR-ABL1$^+$ Acute Lymphoblastic Leukemia (ALL) has been extensively studied, proving the IRE1-XBP1 branch to be required for leukemic cell survival. However, a therapeutic strategy involving UPR inhibition that possesses translational impact is yet to be identified.
Aims: In this study we aim to identify a potential synergistic effect of simultaneous pharmacological inhibition of IRE1 and BCR-ABL1 in BCR-ABL1$^+$ ALL.
Methods: To study the link between IRE1-XBP1 axis of UPR and BCR-ABL1 we utilized both pharmacological and genetic approaches. 1) We tested the effect on proliferation and viability of pharmacological IRE1 inhibition (using MKC-8866) alone and in combination with Tyrosine Kinase Inhibitors (TKI, using Imatinib or Nilotinib) on BCR-ABL1$^+$ human ALL cell lines, SUP-B15 and TOM-1. The cell lines were also co-cultured with immortalized tertMSCs to test the chemo-protective effect of bone marrow stromal cells (BMSCs) on leukemia cells. 2) We tested whether genetic knock-down of XBP1 could sensitize cells towards the effect of Imatinib and Nilotinib. To this end, primary murine pre-B cells from conditional XBP1$^{fl/+}$mice were transduced with BCR-ABL1 construct, and with either inducible cre or empty vector.
Results: IRE1 inhibitor MKC-8866 (MKC) in combination with either Imatinib (IM) or Nilotinib (NL) showed enhanced capacity to arrest proliferation and to induce cell death in BCR-ABL1$^+$ALL cell lines compared to single treatments, after 3 days incubation (Viable SUP-B15: MKC 30μM 94.9%±0.1, IM 10μM 78.4±0.4, Combination 17.0±1.4; MKC 30μM 94.1±0.07, NL 5μM 64.2±0.6, Combination 20.0±0.8. TOM-1: MKC 30μM 85.0±0.9, IM 10μM 89.9±0.4, Combination 17.6±0.07; MKC 30μM 94.6±0.1, NL 5μM 71.0±0.9, Combination 30.6±3.6). Using Bliss independence formula, we confirmed a striking synergistic effect. Successively, to exclude any possible off-target effect at the basis of the observed synergism, we used a genetic approach to block IRE1-XBP1 signaling *in vitro*. B-cell precursors from *Xbp1*$^{fl/+}$ mice, instead of *Xbp1*$^{fl/fl}$, were used in order to warrant a basal signal of XBP1, as present during pharmacological inhibition. After transductions with BCR-ABL1, and either cre or the empty vector, we could observe that heterozygous deletion of Xbp1, induced by 4OHT, significantly increased TKI-induced cell death, after 3 days incubation (4OHT 1μM: 47.5%±13.0, IM 1μM: 70.8±1.7, IM+4OHT: 18.3±2.7, NL 0.5μM: 65.2±0.3, 4OHT+ NL: 6.87±1.2). Finally, we showed whether the tested drugs combinations were still effective in presence of BMSCs. It´s know that BMSCs are a critical component to escape TKI-induced cell death in Ph$^+$ leukemia and that IRE1-XBP1 is responsible for chemoresistance in many different cancer types, although this role has never been confirmed in BCR-ABL1$^+$cells. To shed light on this aspect we co-cultured either SUP-B15 or TOM-1 cells with tertMSCs, and while the stroma was capable to block Nilotinib-induced cell death, after 5 days incubation (in SUP-B15, NL 5μM in standard culture 28.7%±1.9, NL 5μM in co-culture 74.9±0.1; in TOM-1, 29.1±2.8 *vs* 78.7±0.4), this protective activity was partially abrogated upon treatment with IRE1 inhibitor. On the other hand, MSCs were not able to reverse IM effect on cell viability.
Summary/Conclusions: Overall, our data demonstrate that simultaneous inhibition of BCR-ABL1 and IRE1 branch of UPR exerts a potent effect *in vitro*, by acting synergistically on BCR-ABL$^+$ ALL cells. This provides basis for a preclinical application of a combined targeted therapy.

E820

HIGH-THROUGHPUT COPY NUMBER PROFILING IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA USING MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION IN COMBINATION WITH NEXT-GENERATION SEQUENCING

D. Alpar[1,*], P.A. Kiraly[1], A. Benard[2], I. Haltrich[3], H. Piko[4], K. de Groot[2], J. Schouten[2], S. Savola[2], C. Bodor[1]

[1]MTA-SE Lendulet Molecular Oncohematology Research Group, 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary, [2]MRC-Holland, Amsterdam, Netherlands, [3]2nd Department of Pediatrics, Semmelweis University, [4]Department of Molecular Genetics and Diagnostics, National Center of Public Health, Budapest, Hungary.

Background: Development, progression and resistance of pediatric acute lymphoblastic leukemia (pALL) are widely associated with recurrent copy number abnormalities (CNAs). Multiplex ligation-dependent probe amplification (MLPA) is an established technique to screen CNAs, thus providing valuable information for risk assessment in pALL; however, the number of simultaneously analyzable genomic loci is limited to 55-60.
Aims: To introduce and test a high-throughput, high-resolution and comprehensive disease-relevant CNA profiling approach applicable to all subtypes of pALL.
Methods: A new digitalMLPA (dMLPA) technique has been developed which combines the advantages of MLPA and next-generation sequencing (NGS), massively extending the number of genomic targets that can be analyzed for their copy number in a single reaction. Bone marrow samples from 58 patients with pALL were analyzed using this novel assay targeting ~470 genomic loci. dMLPA probes contain sample-specific barcodes as well as Illumina adapters. After sequencing, copy number status of each target sequence was assessed by relative read count quantification. Leukemic cell purity (mean: 81%, range: 60-99%) measured by flow cytometry was considered at the interpretation of copy number changes. Results were compared to conventional MLPA, cytogenetic and FISH data.
Results: CNAs directly indicating structural or whole chromosome aberrations or indirectly referring to gene fusions were detected in 93% of patients, in 44/48 pre-B ALL and 10/10 pre-T ALL cases. Among patients with CNAs, recurrent aberrations specifically affecting putative driver genes varied between 0 and 11 (mean: 3.1, total: 175). *ETV6* and *CDKN2A/B* were the most frequently altered genes in pre-B and pre-T ALL, respectively; followed by *CDKN2A/B*, *PAX5*, *RB1*, *VPREB1*, *MLLT3*, *CD200/BTLA*, *TBL1XR1*, *IKZF1*, *CASP8AP2*, *PTEN*, *RUNX1*, *BTG1*, *TP53*, *IKZF2*, *EZH2*, *NF1*, *NR3C2*, *RAG2* and the PAR region genes in pre-B ALL cases and *PTEN*, *MLLT3*, *PTPN2*, *PHF6*, *LEF1*, *CASP8AP2*, *MYB*, *RB1*, *TP53* in pre-T ALL patients. *STIL-TAL1* and *NUP214-ABL1* gene fusions were also observed in T-ALL cases while in one *BCR-ABL1+* pre-B ALL patient, the copy number profile correctly indicated the presence of an extra Ph-chromosome. dMLPA results showed a congruency of 99.3% with those of MLPA mixes containing probes with different ligation sites for a subset of the genes. The increased resolution of dMLPA (*i*) allowed the detection of subclonal aberrations with an improved efficacy and confidence as compared to conventional MLPA and (*ii*) enabled a more patient-specific characterization of CNAs, *e.g.* by revealing 15 different deletion patterns across 23 samples harboring del(9p). In addition to genomic lesions specifically influencing putative or proven clinically relevant genes, 24 structural and 134 whole chromosome aberrations were detected genome-wide which was strongly facilitated by the inclusion of ~200 digital karyotyping probes covering each chromosome arm.
Summary/Conclusions: A novel NGS-based method has successfully been introduced for high-resolution profiling of CNAs in pALL. dMLPA is a robust, fast and cost-effective technique; its input DNA requirement (≥20ng) is similar to those of other low-input NGS protocols and lower than the requirement for MLPA. Due to its targeted approach, data analysis is computationally less demanding as compared to most NGS methods. The number of genomic sites analyzed in our study was an order of magnitude higher than that achievable with conventional MLPA. Due to its specific probe composition, dMLPA allows both high-resolution analysis of genomic driver regions and a genome-wide detection of aneusomies and large CNAs.

E821

CRITICAL ROLE FOR NOTCH SIGNALLING IN B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) DRUG RESPONSE

P. Takam Kamga[1,*], G. Dal Collo[1], M. Midolo[1], A. Adamo[1], A. Gatti[1], R. Carusone[1], M. Bonifacio[1], M. Krampera[1]

[1]Medicine, University of Verona, Verona, Italy

Background: B-cell precursor acute lymphoblastic leukemia (B-ALL) is the leading cause of cancer-related death in children and young adults. There is still a need of more efficient therapies for the subset of refractory patients. Our group has previously shown that Notch-3 and Notch-4 promote human B-ALL cell survival in presence of stromal cell support. However, the prognosis value of Notch signalling as well as its contribution *in vitro* and *in vivo* to chemotherapy has not yet been investigated.
Aims: In this study we used B-ALL cell lines and samples from new diagnosed B-ALL patients to analyse the contribution of Notch signalling to B-ALL pathogenesis in terms of prognosis, proliferation survival and drug response *in vitro* and in mice xenograft models of B-ALL.
Methods: B-ALL cell lines were obtained from ATCC, while B-ALL primary cells were obtained from bone marrow or peripheral blood of 30 B-ALL patients. Flow cytometry and western immunoblotting were used to study the expression of Notch receptors and ligands. Drugs used were Cytarabine (Ara-C), Dexamethasone (Dexa) and Doxorubicin (Doxo) alone or in combination with Notch modulators including anti-Notch blocking antibodies, gamma secretase inhibitors (GSIs), and Notch transcription factor inhibitor (SAHM1). Mice xenograft model of B-ALL were obtained by injecting the B-ALL line RS4;11 in

NOD/Shi-scid/IL-2Rγnull mice (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.
Results: Western blot and flow cytometric analysis showed that B-ALL cell lines as well as primary blast cells displayed the same Notch expression pattern consisting in low expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. Notably, in primary blast cells deriving from patients, the expression of Notch3, Notch4, Jagged2, DLL3 and DLL4 was significantly higher in the cases refractory to treatment as compared to patients achieving complete remission, thus suggesting that Notch signalling could be involved in the response to chemotherapy. In line with this hypothesis, we found that the treatment *in vitro* of B-ALL cell lines with Ara-C or Dexa down regulates the expression of Notch receptors. This down regulation was also observed in human CD19+ blast cells isolated from bone marrow of recipient mice treated with Ara-C compared to cells isolated from not treated mice. In addition, Notch inhibitors significantly improved *in vitro* the cytotoxicity of Ara-C, Dexa and Doxo towards B-ALL cell lines. Finally, we observed that the administration to mice of a pan Notch inhibitor, *i.e.* the GSI XII, significantly lowered the CD19+ leukemic burden in the bone marrow of recipient mice, potentiating anti leukemic effect of ARA-C.
Summary/Conclusions: In this study we used both *in vitro* and *in vivo* assays to highlight the prognostic value of Notch expression in B-ALL as well as its critical role in B-ALL cell survival and response to chemotherapy. We also demonstrated that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

REGULATION OF NOTCH AND WNT SIGNALING PATHWAYS BY NRARP IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

I. Pinto[1], M. L. Oliveira[1], J. T. Barata[1], R. Fragoso[1,*]
[1]JBarata Lab, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy. Although the outcome of T-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver in T-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. We have shown that loss of *mir-181ab1* blocks Notch-induced T-ALL development partly by de-repressing the expression of NRARP (NOTCH regulated ankyrin repeat protein) a negative regulator of NOTCH signaling. Importantly, NRARP over-expression in murine hematopoietic stem cells impairs T-cell development suggesting that de-regulation of NRARP expression can contribute to the pathogenesis of T-ALL.
Aims: To investigate the role of NRARP in human T-ALL cell growth and survival and its therapeutic potential in T-ALL.
Methods: mRNA and protein expression were determined by real time-PCR and western blot analyses. *in vitro* functional evaluation of NRARP in T-ALL cell lines was performed by flow cytometry analysis of proliferation and viability upon NRARP overexpression using lentiviruses.
Results: We started by characterizing NRARP expression in human T-ALL cells and compared it with the expression of NRARP in human thymocytes. We found that NRARP protein levels are significantly increased in T-ALL cells. This result, although consistent with the fact that NRARP is a transcriptional target of NOTCH, suggests that NRARP is not sufficient to block NOTCH oncogenic signals. To test this hypothesis, we overexpressed NRARP in human T-ALL cell lines. Curiously, NRARP overexpression blocks the expansion of the T-ALL cell lines that display *NOTCH1*-activating mutations but promotes the expansion of the T-ALL cells without *NOTCH1* mutations. Although in both cell types (WT and *NOTCH1*-mutated) NRARP overexpression blocks NOTCH signaling, in *NOTCH1*-WT T-ALL cells we observe an increase in c-Myc expression. Consistent with these results, *NOTCH1*-WT NRARP overexpressing cells are more sensitive to JQ1, a small-molecule bromodomain inhibitor that targets c-Myc. NRARP is known to positively regulate LEF1, a DNA binding transcription factor acting downstream of WNT. Thus we sought to investigate the impact of NRARP in this signaling pathway. Very interestingly, our results show that in *NOTCH1*-mutant cell lines NRARP overexpression results in the down-regulation of the WNT signaling pathway while in *NOTCH1*-WT *T-ALL* cells results in its up-regulation.
Summary/Conclusions: Taken together our results suggest that NRARP may play a dual role in T-ALL pathogenesis, regulating both NOTCH and WNT pathways, with opposite functional effects on leukemia cells depending on NOTCH mutational status and signaling levels. This dual role may have important biological and therapeutic implications.

ETV6/RUNX1-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA: A NOVEL B-CELL PRECURSOR LEUKEMIA SUBTYPE IDENTIFIED BY THE CD27/CD44 IMMUNOPHENOTYPE

M. Zaliova[1,2,3], M. Kotrova[1,2,3], S. Bresolin[4], J. Stuchly[1,3], J. Stary[1,2], O. Hrusak[1,2,3], G. te Kronnie[4], J. Trka[1,2,3], J. Zuna[1,2,3], M. Vaskova[1,3,*]
[1]Department of Paediatric Haematology and Oncology, Second Faculty of Medicine, Charles University, [2]University Hospital Motol, [3]CLIP - Childhood Leukaemia Investigation Prague, Prague, Czech Republic, [4]Department of Women's and Children's Health, University of Padova, Padova, Italy

Background: We have shown previously that *ETV6/RUNX1*-positive acute lymphoblastic leukemia (ALL) is distinguishable from other ALL subtypes by CD27^{pos}/CD44$^{low-neg}$immunophenotype. During diagnostic immunophenotyping of 573 childhood B-cell precursor ALL (BCP-ALL), we identified eight cases with this immunophenotype among "B-other ALL" (BCP ALL cases negative for hyper-/hypodiploidy, *ETV6/RUNX1*, *TCF3/PBX1* and *BCR/ABL1* fusion genes and *KMT2A*-rearrangements).
Aims: We aimed to characterize their genetic and biological background, to reveal to what extent they resemble *ETV6/RUNX1*-positive ALL and to elucidate whether they belong to the recently described *ETV6/RUNX1*-like ALL (Lilljebjörn et al., Nature Communications 2016).
Methods: We utilized microarrays to study the gene expression profile (GEP) and biological similarity of the BCP-ALL subtypes. Five *ETV6/RUNX1*-positive and five hyperdiploid ALL cases were analyzed using microarrays in parallel to seven CD27^{pos}/CD44$^{low-neg}$ B-other cases with available material. Microarray data from all 17 BCP-ALL cases were combined with data from an independent Italian cohort of 291 BCP-ALL cases (including *ETV6/RUNX1*-positive, *BCR/ABL1*-positive, *TCF3/PBX1*-positive, *KMT2A*-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).
Results: In the hierarchical clustering based on GEP all five *ETV6/RUNX1*-positive cases and 5 of 7 CD27^{pos}/CD44$^{low-neg}$ B-other cases clustered within the *ETV6/RUNX1*-positive cluster. These B-other cases were thus classified as *ETV6/RUNX1*-like ALL. We identified multiple regions of acquired copy number aberrations (CNA)/ uniparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusion transcripts each in one patient. The most important findings are summarized in Figure 1. All 5 *ETV6/RUNX1*-like cases harbored a deletion of the *ETV6* gene, resulting in an in-frame *ETV6/BORCS5* fusion in one of them. The deletion of *ARPP21* was found in 3 cases, and the deletions of *PAX5*, *ATP10A*, *BTG1* and the gain of *RUNX1* were found in 2 cases each. The *ARPP21* deletions displayed a strikingly uniform character and were highly enriched in *ETV6/RUNX1*-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the *ETV6/BORCS5.* Integrating data from all platforms, we identified *IKZF1* as another recurrently affected gene; a deletion, a nonsense mutation and an *IKZF1*-involving out-of-frame fusion were each found in one case. The *P2RY8/CRLF2* fusion and the *TCF3/ZNF384* fusion (the former co-occurring with two activating *JAK2* mutations) were found in 2 CD27^{pos}/CD44$^{low-neg}$ B-other cases that were closer to other BCP-ALL subtypes than to *ETV6/RUNX1*-positive ALL as indicated by GEP.

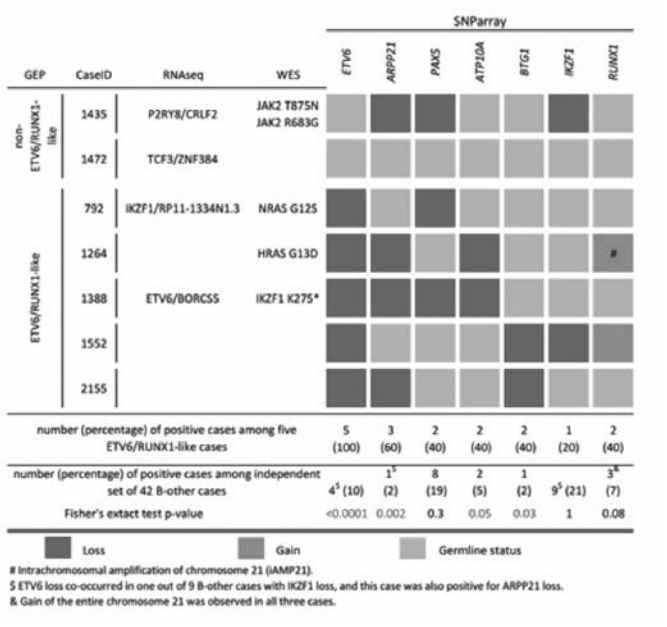

Figure 1.

Summary/Conclusions: We showed that similarly to *ETV6/RUNX1*-positive ALL, *ETV6/RUNX1*-like ALL is also associated with CD27^{pos}/CD44$^{low-neg}$ immunophenotype. We identified deletion of *ARPP21* to contribute to the specific genomic profile of *ETV6/RUNX1*-like ALL in addition to lesions of *ETV6*

and *IKZF1*. In conjunction with the single published study, our study establishes the *ETV6* lesion as the only common genetic aberration and thus the most likely key driver of *ETV6/RUNX1*-like ALL.

GENETIC ALTERATIONS IN CHILDREN WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN TAIWAN

D.-C. Liang[1,*], T.-C. Yeh[1], H.-C. Liu[1], T.-H. Jaing[2], S.-H. Chen[2], J.-Y. Hou[1], Y.-J. Huang[3], H.-W. Yao[1], T.-Y. Huang[3], T.-H. Lin[3], C.-P. Yang[3], L.-Y. Shih[2]
[1]Mackay Children's Hospital and Mackay Medical College, Taipei, [2]Chang Gung Memorial Hospital and Chang Gung University, [3]Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China

Background: The leukemogenesis of T-cell acute lymphoblastic leukemia (T-ALL) involves multistep processes of genetic alterations.
Aims: We aimed to determine the genetic alterations including common fusion transcripts, overexpression of T-cell transcription factor oncogenes and deletion or mutations of targeted genes in pediatric T-ALL in Taiwan as well as their impact on outcomes in those treated with TPOG-ALL-2002 protocol.
Methods: Between 1995 and 2015, bone marrow samples from 102 children (<18 years old) consecutively diagnosed with T-ALL were examined. *SIL-TAL1, MLL-ENL*, and *CALM-AF10* transcripts were detected by RT-PCR assays. RQ-PCR with TaqMan assays were used to measure the expression of *HOX11, TAL1,* and *LYL1* oncogenes expressed as normalized copy number (NCN) to *ABL* internal control gene. *TAL1* overexpression was defined as NCN > the lowest level of *SIL-TAL1* positive patients. Overexpression of *HOX11* and *LYL1* was defined as NCN > the upper limits of the 50 normal bone marrow controls. Mutations of *NOTCH1*, *FBXW7*, *PHF6*, *JAK1*, *JAK2*, *RUNX1*, *WT1*, *NRAS*, and *KRAS* genes were analyzed by PCR-based assays followed by direct sequencing. *P16* deletion was determined by RQ-PCR or multiplex ligase probe amplification (MLPA), *PTEN* and *PHF6* deletions, *MYB* duplication and *NUP214-ABL1* were detected by MLPA.
Results: The frequency of *SIL-TAL1* fusion transcript was 16.2%, *MLL*-rearranged 5.1%, *CALM-AF10* 1.0%. and no *NUP214-ABL1*. The frequency of *NOTCH1* mutations was 46.9%, *FBXW7* 13.0%, *RUNX1* 5.2%, *WT1* 6.3%, *NRAS* 6.2%, *KRAS* 2.1%, and no *JAK1* or *JAK2* mutations. *P16* deletion was present in 56.2%, *PTEN* in 11.1%, *PHF6* deletion/mutation in 13.4%, and *MYB* duplication in 4.8%. Overexpression of *TAL1* was present in 46.5%, 22% for *LYL1*, and 9% for *HOX11*. The correlation among the genetic alterations showed that *LYL1* overexpression occurred more frequently in *P16* wild-type compared with *P16*-deleted patients (P=0.0003) and absence of *SIL-TAL1* transcript was significantly associated with *LYL1* overexpression (P=0.018). A comparison of outcomes was made according to the status of each genetic abnormality. *NOTCH1* mutations conferred a favorable overall survival (OS) (P=0.025). *PHF*6 deletion/mutation conferred an inferior OS (P=0.030). *PTEN* deletion was associated with shorter relapse-free survival (RFS) (P<0.0001) and OS (P<0.0001). Status of other gene mutations, deletion or duplication did not influence the RFS or OS. *TAL1* overexpression predicted a higher risk of relapse (37% *vs* 21%, P=0.006), an inferior RFS (P=0.002) and OS (P=0.025) whereas *HOX11* or *LYL1* overexpression had no prognostic impact. By multivariate analysis, *NOTCH1* mutation did not reach statistical significance for an independent predictor of OS (HR 0.167, P=0.112), *PHF6* deletion/mutation was an independent unfavorable predictor for OS (HR 4.596, P=0.006), and *PTEN* deletion was also an independent predictor for both RFS (HR 29.493, P=0.007) and OS (HR 15.830, P=0.003). *TAL1* overexpression was an independent risk factor for both RFS (HR 3.699, P=0.014) and OS (HR 2.701, P=0.047).
Summary/Conclusions: The present study showed that *LYL1* overexpression was negatively associated with *SIL-TAL1* or *P16* deletion. *PHF6* deletion/mutation, *PTEN* deletion, and *TAL1* overexpression were the independent predictors of adverse outcomes. COMPUTATIONAL METHODS TO FIND NEW THERAPEUTIC TARGETS IN ALL, SYSTEMATICAL IDENTIFICATION OF ESSENTIAL GENES

L. Ekdahl[1,*], M. Pertesi[1], A. Palm[1], L. Järvstråt[1], E. Johnsson[1], U. Gullberg[1], A.-K. Wihlborg[1], B. Nilsson[1]
[1]Division of Hematology and Transfusion Medicine, Lund University, Lund, Sweden

Background: Deletion of chromosomal material is a hallmark of cancer genomes. While these lesions primarily target tumour suppressor genes, neighbouring genes are frequently co-deleted en passant. Loss of one copy(haploinsufficiency) of a neighbouring gene that is essential for the survival of the cancer cells may constitute potential therapeutic targets in that the cancer cells may be selectively sensitive to further suppression of the function of that gene. Identifying such vulnerabilities is one of the current challenges in cancer genomics. We show that vulnerabilities in cancer cells can be identified computationally by applying pattern recognition techniques to a copy-number dataset. This approach will identify genomic regions with potential essential genes. Genes in these regions can be evaluated downstream by genome editing techniques to find novel targets for treatments. Using pattern recognition techniques to find essential genes is a straight-forward, easily applied and non time-consuming method compared to genome wide experimental approaches.
Aims: Develop a computational framework to find regions with potential essential genes from copy-number data, with a primary focus on hematological malignancies and in particular ALL.
Methods: Our computational framework first selected regions of the tumour genome with heterozygous, but not homozygous, deletion. In sections flanking these regions we scanned for linear increases in homozygous deletion frequency. Genes near the start of these increases that have more than one case with homozygous deletion are discarded. Remaining genes were scored by calculating a line of best fit using the least square method towards the nearby peak in homozygous deletion. We sorted the results by settings cut-offs for the slope, amplitude and correlation coefficient of the linear regression line. Genes with the highest scores were then manually evaluated by comparing to known mean copy-number loss dependence score from other data-sets, by graphical visualisation and by investigation of their known function. The data set we analysed contains copy-numbers from tumour samples matched to normal blood samples or normal tissue from the same donor. To validate the essentiality of genes in the discovered regions we used pooled CRISPR/Cas9 editing in ALL cells with and without a deletion of the driving tumour suppressor.
Results: Our framework identified several regions with potential essential genes around well-known tumour suppressors. The strongest signals in the data set were located around the tumour suppressor *CDKN2A*. Downstream analysis with pooled CRISPR/Cas9 editing in ALL cells with and without a *CDKN2A* deletion provided evidence for the essentiality of several genes in this identified region, including one gene that was essential only in *CDKN2A*-deleted cells.
Summary/Conclusions: In conclusion, we explored a computational approach to identify regions with essential genes in copy-number datasets. Application of our approach to real data showed several regions with essential gene candidates around well-known tumour suppressors, indicating the framework works. Downstream genome-editing experiments in model cell-lines provided further evidence for the essentiality of some genes found in such identified regions. While we cannot yet draw conclusions on whether some of these genes are viable therapeutic targets it allows for informed guesses on limited sets of genes for further focused analysis in hematological model cell-lines.

E827

TARGETING ANTIOXIDANT ENZYMES FOR THE TREATMENT OF B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

K. Fidyt[1,*], K. Szczygiel[1], A. Pastorczak [2], A. Graczyk-Jarzynka[1], E. Patkowska[3], E. Lech-Maranda[3], J. Golab[1], M. Firczuk[1]
[1]Department of Immunology, Medical University of Warsaw, Warsaw, [2]Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Lodz, [3]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease characterized by abnormal expansion of B cell precursors and is mainly affecting children and adolescents. The backbone of the treatment is chemotherapy providing high cure rates in pediatric ALL (> 85%) but much worse treatment response is observed in adolescents and adults (< 50%). Patients who relapse develop refractory, chemotherapy resistant disease and remain a clinical challenge. Growing body of evidence suggests that disturbance of redox homeostasis is a promising anticancer approach. Due to high metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidants for their survival. One of the oxidative stress protectors are peroxiredoxins (PRDXs) that next to thioredoxins (TXNs) belong to the TXN-family and are the key components of TXN antioxidant system. PRDXs are enzymes involved in scavenging peroxides. TXNs are responsible for cysteine-thiol disulfide exchange in numerous protein substrates.
Aims: To investigate the potential of targeting the TXN antioxidant enzymes as a novel pro-oxidative strategy in B-ALL treatment.
Methods: We have used three different cell lines representing distinct cytogenetic subgroups of B-ALL: BV-173 (BCR-ABL), SEMK-2 (MLL-AF4) and NALM-6 (complex cytogenetics). ROS levels were measured using Cell ROX assay. RNA and protein levels of TXN-family enzymes were measured by quantitative PCR and immunoblotting, respectively. Downregulation of PRDX1 was established by a novel CRISPR/Cas9 gene editing system. We have employed lenti-

CRISPR v2 plasmid to produce lentiviral vectors encoding PRDX1-specific sgRNA and Cas-9 and used them to generate BV-173 cells with PRDX1 genomic deletion. Proliferation rate was evaluated by trypan blue exclusion method. Cytostatic/cytotoxic effects of TXN-family enzymes inhibitors, such as adenanthin (ADE), auranofin (AUR) and SK053 were assessed by MTT viability assay and by detection of propidium iodide-positive cells in flow cytometry.

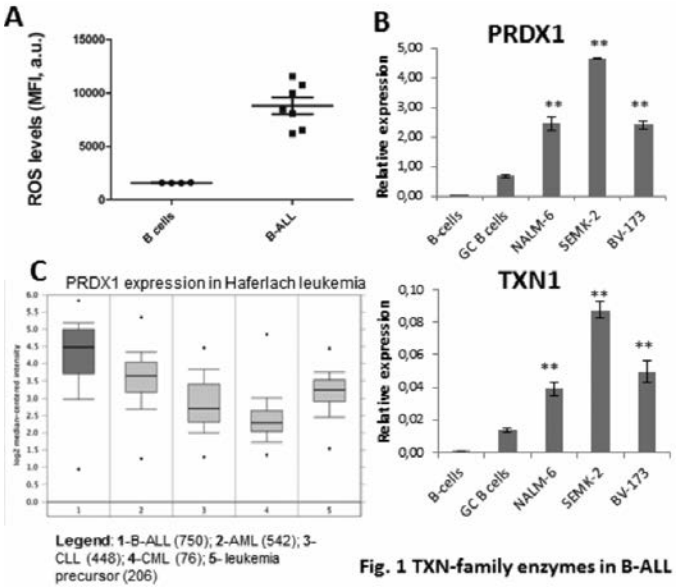

Figure 1.

Results: We have found that B-ALL cell lines exhibit significantly higher levels of ROS as compared to normal B cells isolated from human tonsils (Fig.1A). In accordance with this observation, our analysis of TXN antioxidant enzymes gene expression in B-ALL cell lines showed their upregulation (Fig.1B). Analysis of deposited data revealed that PRDX1 expression level is the highest in B-ALL among the other types of leukemia (Fig.1C). Moreover, we have observed elevated expression of PRDX1 in malignant lymphoblasts derived from pediatric patients at both RNA and protein levels. Genomic deletion of PRDX1 in BV-173 cells leads to suppression of their proliferation rate, comparing to parental cells and cells transduced with mammalian non-targeting sgRNA. These results allow us to suspect that PRDX1 may play growth-supporting role in these cells. Targeting TXN-family enzymes was also performed with the use of various small molecule inhibitors. Both B-ALL cell lines and primary cells are sensitive to PRDX and TXN inhibitors, which reduce cell viability in dose-dependent manner.

Summary/Conclusions: All the above results suggest that targeting TXN antioxidant system may exert desirable anticancer effects in the treatment of B-ALL. Inhibitors of TXN-family enzymes can be considered as putative agents to use in combination with classical drugs and improve existing therapeutic approaches. Further studies are underway.

E828

RNA-BINDING PROTEIN IGF2BP1 PROMOTES SURVIVAL OF ETV6/RUNX1 LEUKEMIA CELLS

M. Stoškus[1,*], G. Vaitkevičienė[2], A. Eidukaitė[3,4], L. Griškevičius[1,5]
[1]Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariškių Klinikos, [2]Center for Pediatric Oncology and Hematology, Children's Hospital, Affiliate of Vilnius University Hospital Santariškių Klinikos, [3]Department of Laboratory Medicine, Children's Hospital, Affiliate of Vilnius University Hospital Santariškių Klinikos, [4]Department of Immunology, State Research Institute Centre for Innovative Medicine, [5]Faculty of Medicine, Clinics of Internal, Family Medicine and Oncology, Vilnius University, Vilnius, Lithuania

Background: The IGF2 mRNA binding protein 1 (IGF2BP1, other aliases IMP-1 (IMP1), CRD-BP (CRDBP), ZBP-1 (ZBP1), and VICKZ1) belongs to a family of regulatory RNA-binding proteins with an oncofetal expression pattern. IGF2BP1 has also been identified to be exclusively specific for ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) but biological significance of IGF2BP1 overexpression has not been thoroughly investigated to date (Andersson, Olofsson *et al.* 2005; Stoskus, Gineikiene *et al.* 2011). We have recently contributed by reporting that ETV6/RUNX1 transcript is a target of RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL, suggesting a role of IGF2BP1 in ETV6/RUNX1-mediated leukemogenic events (Stoskus, Vaitkeviciene *et al.* 2016).

Aims: To define the biological significance of IGF2BP1 overexpression in t(12;21)(p13;q22) ETV6/RUNX1-positive ALL.

Methods: In this study we have used stable sublines with downregulated IGF2BP1 from our previously published study (Stoskus, Vaitkeviciene *et al.* 2016). Dynamics of viable cell population was assessed by flow cytometry using 7-AAD staining (BD Biosciences) following 72 hrs culture in complete medium. An EdU flow assay (Thermo Fisher Scientific, TFS) was used to assay DNA replication in proliferating cells. Spontaneous and doxorubicin (Doxo), staurosporine (STS), and STAT3 selective inhibitor S3I-201 (all from Santa Cruz Biotechnology) induced cell death rates were determined by Annexin V (TFS) and 7-AAD staining. All samples were analyzed on Accuri C6 cytometer (Accuri Cytometers) using CFlow Plus and FCS Express software (De Novo Software). IGF2BP1, ETV6/RUNX1, and STAT3 RT-qPCR was performed essentially as reported previously (Stoskus, Gineikiene *et al.* 2011). Statistical analyses performed using GraphPad Prism software (GraphPad Software).

Results: Downregulation of IGF2BP1 by 2-fold have rendered into approximately 2-fold lower population growth rate, increasing levels of spontaneous cell death in dynamics, and modest yet statistically significant attenuation of cell cycle progression (35.13% *vs* 40.40%, p<0.0001). Data from treatment with 50 nM of Doxo, 250 nM of STS suggest that IGF2BP1 downregulation has no effect on pharmacological effectiveness of these drugs. In contrast, IGF2BP1-downregulated cells are more sensitive to pharmacological inhibition of STAT3 even upon treatment with suboptimal 25 μM concentration of S3I-201. Lastly, we have probed if STAT3 transcript levels could be sustained by IGF2BP1 protein as in agreement with previously reported (Stohr, Kohn *et al.* 2012) and our unpublished insights from anti-IGF2BP1 RNA immunoprecipitation datasets. Correlation analysis of RT-qPCR data have confirmed these assumptions as downregulation of IGF2BP1 expression have resulted in a decrease of ETV6/RUNX1 mRNA (r2=0.8253, p<0.001, slope 0.9459) and also STAT3 transcript levels (r2=0.7709, p=0.002, slope 0.6436). These data suggest that STAT3 transcript is also a potentially regulated by RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL model cells (Fig 1).

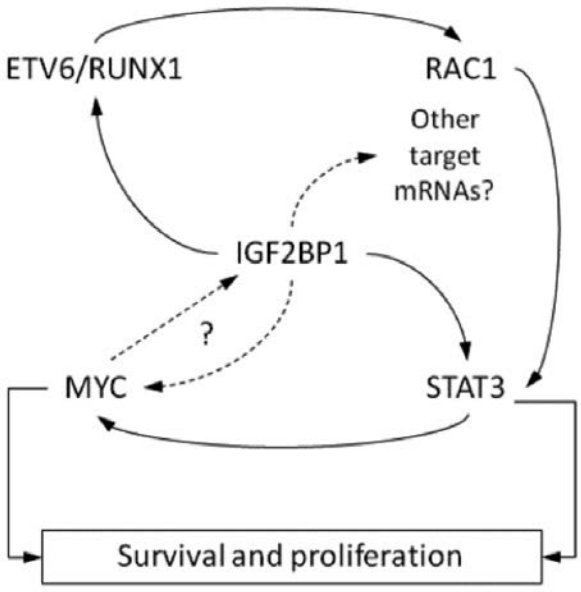

Figure 1.

Summary/Conclusions: We provide evidence that IGF2BP1 promotes survival of t(12;21)(p13;q22)-positive ALL model cells through cell cycle progression and preventing spontaneous cell death. Potentiation of ETV6/RUNX1®STAT3 signaling axis is one of the possible mechanisms responsible for this phenotype as IGF2BP1 maintains appropriate levels of primarily ETV6/RUNX1 and also STAT3 mRNAs. Further studies are clearly warranted to further delineate the role of IGF2BP1 in t(12;21)(p13;q22)-positive ALL (Stoskus, Eidukaite *et al.* 2016).

6-MERCAPTOPURINE PROMOTES ENERGETIC FAILURE IN LEUKEMIC T-CELL LINE JURKAT

A.A. Fernandez Ramos[1,2,*], C. Marchetti-Laurent[1,2], V. Poindessous[1,2], S. Antonio[2,3], P. Laurent-Puig[1,2,4], S. Bortoli[2,3], M.-A. Loriot[1,2,4], N. Pallet[1,2,4]
[1]INSERM UMRS-1147, [2]Université Paris Descartes, [3]INSERM UMR-S 1124, [4]Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France

Background: 6-Mercaptopurine (6-MP) is a thiopurine drug with antiproliferative effects by blocking purine synthesis. 6-MP is largely prescribed for the treatment of childhood acute lymphoblastic leukemia (ALL). Recent evidence

suggest that 6-MP inhibits the phosphatidylinositol 3 kinase (PI3K)/ mammalian target of Rapamycin (mTOR) signaling pathway and modulates the transcriptional activity of hypoxia inducible factor 1 α (HIF-1α). As mTOR and HIF-1α are key mediators of metabolic reprogramming in cancer and normal T cells we hypothesized that 6-MP can impact cellular metabolic remodeling through its action on nucleotide synthesis. Metabolic reprogramming fosters glycolysis, glutaminolysis, and biosynthesis of lipids and nucleotides to sustain cell growth and proliferation, a key feature of cancer cells. This metabolic switch is regulated by metabolic checkpoints, including mTOR, AMP-activated protein kinase (AMPK) and the oncogenes Myc and HIF-1α.

Aims: Our objective is to study the impact of the antiproliferative molecule 6-mercaptopurine (6-MP) on proliferating T-leukemia cells metabolic reprogramming.

Methods: *In vitro* experiments were performed in a Jurkat T cell line. Cells were incubated with 6-MP from 6h to 72h. We used RT-PCR, Western Blot, glucose uptake and glycolytic and glutaminolytic flux to evaluate the metabolic effects of 6-MP.

Results: Our results showed that 6-MP reduces ATP content as early as after 2 hours of treatment and this decrease is maintained up to 72 hours. As AMPK is an energetic sensor activated with low ATP content, we studied AMPK activation after 6-MP treatment. We observed that 6-MP treatment activates AMPK after 6 and 48 hours of treatment. Moreover, 6-MP significantly modifies the transcriptional reprogramming of genes implicated in glycolysis, glutaminolysis and nucleotide synthesis after 24, 48 and 72 hours of treatment. In addition, 6-MP inhibits the expression of the metabolic checkpoints mTOR, HIF-1α and Myc after 24, 48 and 72 hours of treatment. 6-MP also decreases glucose and glutamine oxidation after 48 hours of treatment by 60% and 35%, respectively, suggesting that 6-MP inhibited TCA (tricarboxylic acid cycle) and OXPHOS (oxidative phosphorylation). The production of lactate, a marker of aerobic glycolysis, is significantly decreased by 30% after 6-MP treatment for 48 hours, meaning that aerobic glycolysis is also inhibited. However, 6-MP has no effect on glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A) protein expression, suggesting that 6-MP metabolic effects are not linked to glucose uptake.

Summary/Conclusions: In conclusion, our findings offer new insights on the cellular effects of 6-MP treatment by promoting an early energetic stress that influence proliferation and raise apoptosis in leukemia T cells. Interestingly, the inhibition of the metabolic checkpoints (mTOR, HIF-1α, Myc) and the diminution of glycolytic and glutaminolytic fluxes by 6-MP treatment provide an original approach to better understand the cellular effects of 6-MP treatment.

E830

GENETIC ABERRATIONS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA AND THEIR IMPACT ON CLINICAL OUTCOME

K. Takahashi[1,*], F. Wang[2], K. Patel[2], C. Bueso-Ramos[2], X. Song[2], J. Zhang[2], C. Gumbs[2], L. Latasha[2], S. Tippen[2], T. Kadia[1], F. Ravandi[1], G. Garcia-Manero[1], N. Short[1], N. Jain[1], M. Konopleva[1], H. Kantarjian[1], A. Futreal[1], E. Jabbour[1]
[1]Leukemia, [2]UT MD Anderson Cancer Center, Houston, United States

Background: Genetic alterations have prognostic impact on pediatric patients with B cell acute lymphoblastic leukemia (B-ALL). Genomic landscape and its impact on clinical outcome is less understood in adults with B-ALL.

Aims: To describe the landscape of genomic aberrations and analyze the correlation with clinical characteristics and prognostic impact in adults with B-ALL.

Methods: We assessed bone marrow specimens from 64 consecutive adults with a median age of 51 years (range 18 to 80) with previously untreated B-ALL between 2012 and 2015. The cohort included 23 Philadelphia chromosome (ph)-positive and 41 Ph- negative B-ALL. Sixty patients (94%) were treated with Hyper-CVAD (hyperfractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone alternating with high-dose methotrexate and cytarabine)-based regimen; 23 of them received additional tyrosine kinase inhibitor for Ph-positive disease (dasatinib [N=4] or ponatinib [N=19]). Four patients (6%) were treated with augmented BFM (Berline-Frankfurt-Munster) regimen. Genomic DNA extracted from pre-treatment bone marrow specimens were sequenced by targeted capture exome sequencing of 295 genes that are recurrently mutated in hematologic malignancies (median 280x coverage). The panel included more than 1000 cytoSNP position evenly distributed among the genome that allowed estimation of copy number variations (CNVs). Point mutations were called by modified Mutect/Pindel algorithm.

Results: Among the 64 patients, we detected 70 point mutations in 40 genes in 38 patients (54%). Ph-positive ALL had significantly less point mutations than Ph-negative ALL (median number of mutations/patient 0 [range: 0-2] *versus* 1 [range: 0-6], P=0.002). The most frequently mutated genes were *TP53* (17%) followed by *DNMT3A* (9%), *JAK2* (6%), *NRAS* (6%), *NF1* (5%), *PAX5* (5%), *RUNX1* (5%), and *TET2* (5%). *TP53* mutations were strongly associated with Ph-negative B-ALL (P=0.004) and low hypoploidy (P=0.009). Recurrent CNVs involved loss/deletion in genes such as *PAX5* (38%), *TCF3* (38%), *IKZF1* (31%), *CDKN2A/2B* (31%), *BTLA* (25%), *CD200* (22%), *ETV6* (22%), *RB1* (20%), *mir15*-a/*16*-1 (15%), *ERG* (14%), and *MLLT3* (11%), whereas gain/amplification was detected in *NR3C2* (18%), *ERG* (15%), *RUNX1* (15%), and *LEF1* (14%). *MLLT3* loss/deletion was specific to Ph-negative- ALL (0% for Ph-positive *versus* 17% for Ph-negative, P=0.036) and Mir15-a/16-1 loss/deletion had non-statistically significant association with Ph- BALL (4% *versus* 22% respectively, P=0.06). In this cohort, 78% and 100% of the Ph-negative and Ph-positive ALL achieved complete remission, respectively. None of the point mutations or CNVs were associated with differential response to therapy. Survival analysis was stratified by Ph status. Complex karyotype had trend toward worse event-free survival (EFS) (median EFS 3.6 months *versus* 26.3 months, P=0.06) in Ph-negative ALL. None of the point mutations or CNVs were associated with EFS/overall survival (OS) in Ph-negative ALL. Notably, *TP53* mutation nor low hypoploidy did not affect EFS/OS in the current cohort. In Ph-positive BALL, *IKZF1* deletion/loss was associated with a trend toward worse EFS (median EFS 3.6 months *versus* 21.3 months, P=0.07) but it did not affect OS.

Summary/Conclusions: Genetic analysis highlights the molecular heterogeneity of adult B-ALL. Adult B-ALL is frequently associated with CNVs and point mutations are less frequent. Prognostic impact of genetic alteration in adult B-ALL appears to be limited except for *IKZF1* deletion/loss, which may predict worse EFS in Ph-positive BALL.

Background: The survival rate of relapsed adult acute lymphoblastic leukemia (ALL) is around 10%.

Aims: We looked for recurrent Copy Number Alterations (CNA) in relapsed adult B cell progenitor ALL (BCP-ALL) to shed light into the molecular mechanisms of relapse.

Methods: BM or PB samples with at least 30% of blasts from 31 adult BCP-ALL patients at 1st relapse and, of them, 21 paired diagnosis and relapse samples were analysed by MLPA (MRC-Holland, The Netherlands). 19 out of these 21 paired samples were analysed by SNP array with CytoScan HD chips (Affymetrix, Santa Clara, California, USA). True CNA were considered when encompassed a minimum of 25 markers, and 25 markers and ≥20Mb for CN-LOH.

Table 1.

Xp22.33-p22.11		5/15	*TBL1X, CDKL5, EIF1AX, PDK3*
Xq28		4/15	*L1CAM, DKC1, RPL10, IRAK1, TAZ, IKBKG, IL9R, BRCC3*

Results: With a median follow up of 12.43 [2.4;30.3] months, the median OS of the 31 patients at first relapse was 7.9 months, [2,4;13,5]. The OS of patients at first relapse was significantly lower in those having more than 3 CNA by MLPA (median ≤3 CNA 9.7 months [0-20.7] *vs* median >3 CNA 4.2 months (0.6-7.8), p=0.042). CDKN2A/B deletion was the most common CNA observed at relapse (16/31, 52%) and most of these deletions were homozygous (12/16, 75%). Comparing paired CDKN2A/B deletions, homozygous were more frequent at relapse (from 8 heterozygous CDKN2A/B deleted patients at diagnosis, 7 became homozygous at relapse, p=0.070). SNP arrays detected 554 CNA (409 DEL, 125 DUP and 20 LOH) in 34 samples of 19 patients. At diagnosis (n= 16 patients) the mean number of CNA was 12.3 (9.6 DEL, 2.3 DUP and 0.4 LOH) while in first relapse (n=13 patients) was 17.8 CNA (12.6 DEL, 4.2 DUP and 1 LOH) and in second relapse (n=5 patients) was 21 CNA (14.6 DEL, 6.4 DUP and 0 LOH)(p=0.007). All matched diagnosis and first relapse samples (available for 10 patients) showed common CNA. In 6/10 cases some of CNA were retained from diagnosis while others were acquired or lost at relapse (suggesting evolution from an ancestral clone), 3/10 shared all CNA from diagnosis and acquired new CNA at relapse (indicating an evolution from diagnosis clone) and 1/10 showed the same CNA signature at relapse (suggesting a primary resistance of the diagnosis clone). Gene ontology analysis showed a significant enrichment of gene deletions involving B cell differentiation, activation and proliferation, and regulation of cytokine-mediated signaling pathway at relapse (Benjiamini Hochberg test, p<0.01). Table 1 summarizes the frequencies of the most retained or acquired CNA at relapse in at least 4 out of 15 patients. Besides the high genetic heterogeneity observed, some recurrent CNA could be identified such as 9p, 11q, 12p, 22q and 7p deletions and 1q, 8q, 17q, 21+ and Xp duplications. In addition, deletions in important tumor suppressor genes such as *TP53*, *FOXO1*, *FOXO3* or *RB1* were detected in 3 patients.
Summary/Conclusions: BCP-ALL has a high genetic heterogeneity at relapse, with most of the genetic alterations playing important roles for disease progression. This heterogeneity points out the need for search of personalized treatments for patients depending on their molecular alterations. E832

IGF1R/IRS PHARMACOLOGICAL INHIBITION REDUCES CELL PROLIFERATION AND MIGRATION IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

A.P.N. Rodrigues Alves[1,*], J. Machado-Neto[1], R. Scopim-Ribeiro[1], J.C. Fernandes[1], B.A. Fenerich[1], F.B. Da Silva[1], P.S. Scheucher[1], B.P. Simões[1], E.M. Rego[1], A.J. Ridley[2], F. Traina[1]
[1]Internal Medicine, University of Sao Paulo at Ribeirao Preto Medical School, Ribeirao Preto, Brazil, [2]Randall Division of Cell and Molecular Biophisics, King's College London, London, United Kingdom

Background: A recurrent clinical complication of the acute lymphoblastic leukemia (ALL) is the infiltration of lymphoblast into central nervous system. The IGF1/IGF1R signaling pathway is initiated through binding of the ligand (IGF1) to its transmembrane receptor (IGF1R), and the subsequent activation of its substrates, IRS1 and IRS2, which transmit mitogenic and antiapoptotic signals, mainly through the modulation of the PI3K/AKT/mTOR and MAPK signaling pathways. These signaling pathways play an important function in cell proliferation, survival and migration of leukemia cells. We have previously noticed that NT157 (IRS1/2 pharmacological inhibitor) significantly decreased cell viability and induced apoptosis in T-ALL (Jurkat and MOLT-4), and in B-ALL (Namalwa and Raji) cell lines and in primary ALL cells (T-ALL [n=2] and B-ALL [n=2]), although did not presented citotoxicity in peripheral blood mononuclear cells (PBMC) from healthy donors. In addition, NT157 was able to induce the p21 (*CDKN1A*) expression, which is a cell cycle arrest-related gene. We also observed that OSI-906 (IGF1R/IR pharmacological inhibitor) significantly reduced cell viability, but did not induce apoptosis in ALL cell lines tested, and did not modulate viability and apoptosis of primary ALL cells and normal PBMC. The molecular mechanism by which leukemia cells break the blood-brain barrier, allowing the infiltration of the central nervous system and causing serious complications remains poorly understood.
Aims: We herein aimed to investigate the impact of the pharmacological IGF1R/IR and IRS1/2 inhibition on cell proliferation and migration in ALL cells.
Methods: T-ALL Jurkat and B-ALL Namalwa were used. Cell lines were treated or not with NT157 at 0.2, 0.4, 0.8, 1.6 and 3.2μM, or with OSI-906 at 1, 5, 10 and 20μM for 24 and 48 hours. After drug exposure, cell lines were evaluated for cell proliferation (Ki-67 assay), migration (Time-Lapse microscopy analysis) and cell adhesion (using human umbilical vein endothelial cells HUVEC monolayer). Statistical analyzes were performed by the ANOVA. *P* value <0.05 was considered statistically significant.
Results: In Jurkat and Nalmawa cells, NT157 strongly reduces cell proliferation in a dose-dependent manner ($p<0.05$) after 24 hours of treatment. OSI-906 was not able to reduce cell proliferation in these cell lines. The 24 hours treatment with 10μM OSI-906 decreased accumulated distance (μm) and velocity (μm/min), while 0.4μM NT157 reduces only the accumulated distance of Jurkat cells under migration assay into fibronectin monolayer, after being filmed by time-lapse microscopy for 3 hours; the images were captured every 1.5 minutes. Although there is a trend for reduction, cell adhesion between Jurkat and Nalmawa leukemia cells and the human endothelial cell monolayer was not significantly modulated by treatment with both inhibitors.
Summary/Conclusions: The reduction on cell proliferation found during IRS/2 pharmacological inhibition reaffirms the important role of these proteins on malignant phenotype of ALL cells. Migration analysis indicated that NT157 and OSI-906 are potential inhibitors of transendothelial migration in ALL cell lines and contribute with new perspectives on the participation of the IGF1R/IRS1 pathway in the break of the blood-brain barrier.

LEUKEMIA-PROPAGATING CELLS DEMONSTRATED DISTINCTIVE GENE EXPRESSION PROFILES COMPARED WITH THE OTHER CELL FRACTIONS IN PATIENTS WITH DE NOVO PHILADELPHIA CHROMOSOME-POSITIVE ALL

H.-Y. Zhao[1,*], Y. Song[1,2], X.-N. Cao[1], Y.-Z. Qin[1], Y.-Y. Lai[1], H. Jiang[1], Q. Jiang[1], Y. Kong[1], X.-J. Huang[1,2]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Relapse remains one of the major obstacles in Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph^+ALL) even after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Relapse of Ph^+ALL may result from the persistence of leukemia-propagating cells (LPCs), which are defined by their ability to initiate human leukemia and self-renew in immunocompromised mice. In acute myeloid leukemia, higher LPCs frequencies and a gene expression profile typical of LPCs at diagnosis are predictive of unfavorable clinical outcomes. In Ph^+ALL, we recently reported that LPCs are enriched in the $CD34^+CD38^-CD58^-$ fraction using a xenograft assay. Moreover, our cohort study indicate that the LPCs phenotype at diagnosis is an independent risk factor for relapse in Ph^+ALL. However, little is known about the differential gene expression profiles between LPCs and the other cell fractions in *de novo* Ph^+ALL patients.
Aims: To identify the potential molecular basis of LPCs-mediated relapse, the gene expression profiles of the sorted LPCs and other cell fractions from patients with *de novo* Ph^+ALL were compared.
Methods: Twenty patients with *de novo* Ph^+ALL were enrolled for this study at Peking University Institute of Hematology from 2015 to 2016. The LPCs ($CD34^+CD38^-CD58^-$) and other cell fractions (including $CD34^+CD38^-CD58^+$, $CD34^+CD38^+CD58^-$and $CD34^+CD38^+CD58^+$) were sorted from the bone marrow mononuclear cells of *de novo* Ph^+ALL patients (N=3) using a FACS Aria II. Differential expression analysis between LPCs and the other cell fractions were performed using RNA sequencing (RNA-Seq) and the DESeq R package (1.10.1), Gene Ontology (GO) enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. RNA-Seq results were partially validated by a TaqMan-based real-time quantitative polymerase chain reaction (qRT-PCR) technique. Moreover, cell cycle status was compared between LPCs and other cell fractions in *de novo* Ph^+ALL patients (N=20) by flow cytometry.
Results: 1021 genes (301 up-regulated and 720 down-regulated), 1245 genes (354 up-regulated and 891 down-regulated) and 1228 genes (248 up-regulated and 980 down-regulated) were differentially expressed between LPC_1 and Other $Cell_1$ (patient No 1), LPC_2 and Other $Cell_2$ (patient No 2), and LPC_3 and Other $Cell_3$ (patient No 3), respectively. Most of differential expression of genes (DEGs) are related to the regulation of cell cycle and metabolism. GO analysis identified enriched terms of biological functions in DEGs including ATP binding process, ribonucleotide binding process, nucleoside binding process, DNA replication process, primary metabolic process, etc. KEGG analysis showed significantly enriched signaling pathways involved in DEGs including cell cycle, DNA replication, nucleotide metabolic pathways, biosynthesis of amino acids, glutathione metabolism, p53 signaling pathway, etc. Consistent with RNA-Seq results, mRNA levels of the cell cycle-related genes, such as *CDK4* and *HMGB1,* were significantly lower in LPCs fraction than those in other cell fractions. Moreover, the frequencies of quiescent cells in LPCs were significantly higher than those in other cell fractions.
Summary/Conclusions: Distinctive gene expression profiles and cluster, which are mostly related to the regulation of cell cycle and metabolism, were demonstrated between LPCs and other cell fractions in patients with de novo Ph^+ALL. Therefore, our data indicate that it would be of value to develop LPCs biomarkers to contribute to personalized leukemia therapy and the need to identify therapeutic targets directed toward LPCs in Ph^+ALL.

E834

T-CELL LEUKEMIA SENSITIVITY TO FARNESYL TRANSFERASE INHIBITION USING TIPIFARNIB

R. Mondejar[1,*], R. Alonso[1], C. Perez[1], F. Burrows[2], C. Scholz[2], A. Gualberto[2], M.A. Piris[3]

[1]Cancer Genomics Lab, IDIVAL, Santander, Spain, [2]Kura Oncology, La Jolla, CA, United States, [3]Pathology Service, Fundación Jiménez Díaz, Madrid, Spain

Background: T-cell leukemia is a collection of aggressive disorders with unfavorable outcome, in which targeted treatments are still at a preliminary phase. The RAS/MAPK pathway is crucial for TCR signaling of T-cells and it is deregulated in T cell acute lymphoblastic leukemia/lymphoma (T-ALL). Farnesyl transferase inhibitors (FTIs) block the localization of some RAS proteins to the intracellular membrane, thereby inhibiting their activation. Tipifarnib is a potent and specific FTI with a prominent anti-proliferative effect in some *RAS* mutated cells.
Aims: This study test tipifarnib in T-cell lines for *in vitro* sensitivity and for biomarker discovery, both genomic and immunohistochemical.
Methods: We selected those cell lines with available genomic data from COSMIC, CCLE or generated by our group. The MAPK, NFAT, NFKB and JAK/STAT pathways were tested by immunohistochemical analysis over FFPE-cell lines at baseline. The range of drug concentrations to perform IC50 analysis was established between 0-10,000 nM (ten points). Cell proliferation analyses were performed using CellTiter-Glo® Luminescent Cell Viability Assay kit from Promega (Madison, WI, USA), following manufacturer´s instructions at 0h, 48h and 96h. All experiments were done in sextuplet and all numerical data were expressed as the average of the values ± the standard error of the mean. IC50 analyses were performed with GraphPad Prism v5. Clinically-relevant drug sensitivity was defined as IC50 <100nM at 96h. Targeted sequencing was performed in 16 genes known to play a potential role in tumorigenesis in T-cell leukemias.
Results: 59.1% (n=13) of cell lines were sensitive to tipifarnib at concentrations which are readily achievable in the clinic (*i.e.* IC_{50} <100nM at 96h). 45.5%, 50% and 27.3% of cell lines harbored mutations in RAS, RAS-guanine nucleotide exchange factors (GEFs) and RAS-GTPase activating proteins (GAPs) genes, respectively. The mutational state of RAS (p=0.38), RAS-GEFs (p=0.192) and RAS-GAPs (p=1.0) genes were not associated with drug sensitivity. Strikingly, the mutational state of *NOTCH1* was associated with tipifarnib sensitivity. The activation of the MAPK pathway biomarker, ERK, was significantly associated (p=0.046) with drug sensitivity. Conversely, RelB (NFKB pathway) was associated with drug resistance (p=0.007). The same findings were observed with the presence of mutations in RAS-GEFs genes and *NOTCH1* and ERK activation (p=0.015 and p=0.023) and the absence of RelB (p=0.02 and p=0.017).
Summary/Conclusions: This study shows tipifarnib as a potential therapeutic option in T-cell leukemias. The mutational state of *NOTCH1* could constitute a predictor of sensitivity in T-cell leukemias. Furthermore, p-ERK and RelB could serve as potential biomarkers of tipifarnib sensitivity and resistance, respectively.

Acute lymphoblastic leukemia - Clinical

E835

HOSPITALIZATION FOR PATIENTS IN THE U.S. AND EU TREATED WITH INOTUZUMAB OZOGAMICIN *VS* STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA IN A GLOBAL PHASE 3 TRIAL

Y. Su[1,*], I. Van Oostrum[2], E. Vandendries[1], V. Welch[1], F.R. Loberiza[1]
[1]Pfizer Inc, New York, United States, [2]Ingress-health Netherlands, Rotterdam, Netherlands

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, with its once a week one-hour infusion schedule, has demonstrated lower hospital utilization, in association with a clinically meaningful improvement in overall survival, high rate of complete remission, favorable patient-reported outcomes (PRO), and generally manageable safety profile *versus* standard of care (SOC, intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in the phase 3 INO-VATE trial.
Aims: This study aims to determine the regional-specific hospitalization days per patient in the INO-VATE trial.
Methods: Patients receiving study treatment (safety population) and recruited from the US and the EU were included in the analyses. The total number of days hospitalized for each patient was calculated. Hospital days prior to randomization and those after the end of study treatment were excluded. Due to different durations of treatment for InO and SOC (median 1 *vs* 3 cycles), calculations were reported for cycle 1 treatment period (randomization to end of cycle 1) and for the entire treatment period (all cycles - randomization to end of treatment).
Results: A total of 264 patients from the safety population of the phase 3 INO-VATE trial were available for the analyses. 149 were from the US, and 115 from 11 of the EU countries. The percentage of patients requiring hospitalization was lower for InO compared to SOC (Table). The median and mean hospitalization days were shorter for patients in the InO arm compared to the SOC arm across both regions. The difference between the two treatment arms appears to be greater in the US compared to the EU. Hospitalizations in the US appear to be shorter than in the EU, particularly for patients receiving InO.

Table 1. Hospitalizations in R/R ALL patients from the INO-VATE trial.

	Hospitalized N (%)	Mean (Days)	Median (Days) (Min, Max)	Hospitalized N (%)	Mean (Days)	Median (Days) (Min, Max)
	InO (Total N=75)			*SOC (Total N=74)*		
US						
Cycle 1	51 (68%)	11	7 (1, 48)	72 (97%)	23	23 (1, 55)
All cycles	57 (76%)	15	10 (2,53)	72 (97%)	26	25 (4, 81)
EU	*InO (Total N=61)*			*SOC (Total N=54)*		
Cycle 1	46 (75%)	17	15 (3, 56)	48 (89%)	26	27 (3, 43)
All cycles	51 (84%)	25	18 (3, 107)	48 (89%)	33	31 (3, 76)

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO's better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.

E836

NON-INTENSIVE BUT NON-INTERRUPTIVE TREATMENT WITH FEWER ALLO-HSCT IS EFFECTIVE STRATEGY FOR ADULT PH-NEGATIVE B-CELL PRECURSOR (BCP-) ALL: OUTCOME OF THE RUSSIAN PROSPECTIVE MULTICENTER ALL-2009 STUDY

E. Parovichnikova[1,*], V. Troitskaya[2], A. Sokolov[2], O. Gavrilina[2], S. Bondarenko[3], O. Baranova[4], Z. Akhmerzaeva[2], G. Kliasova[5], L. Kuzmina[1], E. Gribanova[2], G. Baskhaeva[2], I. Piskunova[2], T. Obukhova[6], M. Rusinov[7], S. Kulikov[7], V. Savchenko[1]
[1]BMT department, [2]Haematology department, National Research Center for Hematology, Moscow, [3]BMT department, Raisa Gorbacheva Memorial Research Institute for Pediatric Oncology, Hematology and Transplantation, St. Petersburg, [4]Haematology department, N.N. Blokhin Russian Cancer Research Center, [5]Scientific clinical laboratory of clinical bacteriology, mycology and antibiotic therapy, [6]Cytogenetics laboratory, [7]Department of biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: As Ph-negative-BCP-ALL in adults remains less favorable in prognosis than T-ALL, and by expert opinion needs intensive protocols with high portion of allo-HSCT, the results of treatment based on the different approach: de-escalated but non-interruptive treatment with low numbers of allo-HSCT- may be of interest and can provide new insights to the common view.
Aims: to evaluate survival data and risk groups in Ph-neg-BCP-ALL pts in the RALL-study.

Methods: The ALL-2009 (NCT01193933) was initiated in Apr2009. The treatment plan was identical for all risk groups with allo-HSCT indicated only for very high-risk BCP-ALL (t(4;11), t(1;19); WBC >100). Since Apr 2009 till Dec 2016, 329 Ph-negative ALL pts (m.age 28 y (15-55), f/m 147/182) were recruited. Phenotype was unknown in 6 pts, biphenotypic AL was diagnosed in–1,2% (n=4), T-ALL/LBL–in 38,7% (n=125), BCP-ALL-in 59,1% (n=194). Among BCP-ALL there were 54 early pre-B ALL (27,8%), 101 common-ALL (52%), 39 pre-B ALL (20,2%). In BCP-ALL pts m.age was 27 y (15-54), f/m 99/95, initial WBC -9,4*10^9/l (0,4-899,0), LDH 901 IU (31-13059), CNS leukemia- in 17 pts (8,7%), mediastinal mass- in 3 (1,5%), splenomegaly– in 111 (57,2%). Standard cytogenetics was done in 124 pts (64%), 11 had no mitosis, so information is available in 58,2% (n=113). 43,4% of BCP-ALL (n=49/113) pts had normal karyotype (NK); 7,9% (n=9) and 1,8% (n=2) - had t(4;11) and t(1;19) respectively; other abnormalities were detected in 53 (46,9%), including p53 (3,2%), +8 (6,3%), complex karyotype (7,9%), high hyperploidy (16%), delp16 (22,2%), etc. 9 BCP-ALL patients (n=4,7%) were not qualified by the risk in the data-base; 68,1% (n=126) were attributed to the high risk (HR) group (WBC ≥30; EGIL BI, LDH>2N; late CR; t(4;11)-pos). The analysis was performed in Feb 2017. 191 pts were available for induction outcomes, DFS and relapse probability (RP), and all pts – for overall survival (OS).
Results: CR rate in 191 pts was 87,4% (n=167), induction death occurred in 8,9% (n=17), resistance was registered in 3,7% (n=9). Late responders constituted 13,6% (n=26). Death in CR on chemotherapy was 6,3% (n=12) and 1 death after alloHSCT. All-HSCT was performed in 13 (6 – matched related donor, 7 MUD) of 176 patients who survived induction (7,4%), 11 of them – in 1CR. Totally 59 pts (34,9%) had relapsed. At 7y OS for the whole cohort constituted – 54,3%, DFS– 56.5%, RP– 35,4%. In a multivariate analysis for BCP-ALL among common risk factors (age >30y, initial risk group, WBC >30, LDH>2N, immunophenotype, late CR >35d, CNS leukemia, cytogenetics) age, WBC, t(4;11) became statistically significant for OS, DFS and RP. We developed a new threshold for the most valuable risk factors. New risk groups stratification demonstrated 7y OS=79%, DFS=71%, RP=23% in the standard risk (SR) group (age <27y,WBC <75*10^9/l, no t(4;11)) and 46%,45%,47%, respectively, in the HR group (age >27y,WBC>75*10^9/l, t(4;11)).

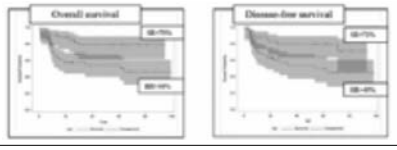

Figure 1.

Summary/Conclusions: Our data demonstrate that non-intensive but non-interruptive treatment with fewer allo-HSCTs is rather effective in adult BCP-ALL producing more than 50% OS at 7 years, though the RP is high. In our study among common risk factors only age, initial WBC and t(4;11) - remained the most valuable markers of poorer prognosis, while immunophenotype, time to CR, CNS involvement, and other cytogenetic markers did not matter. So RALL protocol without intensive highly myelosuppressive consolidation courses and high portion of allogeneic HSCT, may become an alternative and reproducible approach for adult Ph-negative ALL.

E837

POST-INDUCTION MINIMAL RESIDUAL DISEASE RESPONSE DETERMINED BY MULTICOLOR FLOW CYTOMETRY IS A POWERFUL INDICATOR OF EVENT-FREE-SURVIVAL IN THE CHILDHOOD T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Tembhare[1,*], G. Chatterjee[1], I. Sanyal[1], P. Devre[1], S. Ghogale[1], N. Patkar[1], G. Narula[2], B. Arora[2], N. Deshpande[1], Y. Badrinath[1], S. Gujral[1], S. Banawali[2], P. Subramanian[1]
[1]Hematopathology Laboratory, Tata Memorial Centre, Mumbai, Navi Mumbai, [2]Medical Oncology (Paediatrics), Tata Memorial Centre, Mumbai, Mumbai, India

Background: Minimal residual disease (MRD) is a powerful predictor of event-free survival in acute leukemia including T-cell acute lymphoblastic leukemia (T-ALL). Due to lower incidence of T-ALL, MRD studies are limited and restricted to a small cohort of patients. Moreover, flowcytometry based MRD (FC-MRD) studies in T-ALL are very few. AIEOP-BFM group showed that late (Day-78) MRD response determines overall risk-of-relapse and event-free-survival (EFS) using RQ-PCR. However, a larger study by COG (Brent Wood *et al.* ASH, 2014) showed that post-induction (Day-29) FC-MRD was more relevant in the prediction of EFS. This indicates that the best time for MRD evaluation for the risk stratification in T-ALL is still not clear and need more studies. We investigated the value of post-induction FC-MRD response in an assessment of EFS in childhood T-ALL. It is a first T-ALL MRD study from India.
Aims: To investigate the value of 10-color flow cytometry based MRD response in the assessment of EFS in childhood T-ALL
Methods: We studied post-induction (Day-35) MRD (PI-MRD) & post-consolidation (Day-78) MRD (PC-MRD) in bone marrow samples from 100 patients of T-ALL treated under modified MCP-841 protocol between 2014 & 2016. In T-ALL with early-thymic-precursor (ETP) immunophenotype, patients received dexamethasone in place of prednisolone. MRD was performed using 10-color FC-MRD assay on Navios flow-cytometer (Beckman Coulter, BC) and MRD analysis was performed with Kaluza software v-1.3 (BC). Any detectable level of MRD (≥20 events) was defined as MRD-positive. Events included relapse & disease related deaths. Statistical analysis was performed using SPSS v.16.
Results: The median age of patients was 11.5 years (range 2–16 y; M:F–4.6). Based on the immunophenotypic criteria, 13 patients were diagnosed as ETPALL & remaining 87 as not-ETPALL type. PI-MRD was positive in 58/100 (58%) with the median level of 0.23% (range, 0.002% to 6%). PC-MRD was not performed in 71.4% (30/42) of PI-MRD-negative & 1.2% (6/58) PI-MRD-positive patients. PC-MRD was available in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). PC-MRD was positive in 28% (18/64) (median, 0.2% &range, 0.009% to 4%). PI-MRD positivity was significantly high in ETPALL as compared to non-ETPALL (93% *vs* 53%; *p*=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were categorized MRD standard-risk (MRD-SR) if PI-MRD was negative and MRD high-risk (MRD-HR) if PI-MRD was positive with any level. Thus, 42% were categorized as MRD-SR & 58% as MRD-HR. Twenty patients relapsed & of them, six died (2 were ETPALL & 18 non-ETPALL; 3 MRDSR & 17 MRD-HR) within 26 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR (26 months *vs* did not reach; & 70.67% *vs* 92.86%; *p*=0.0017) (Kaplan-Mayer curve shown in Figure 1). Interestingly, there was no difference in EFS for PI-MRD <0.01% *vs* >0.01%, suggesting any level of PI-MRD positive indicated inferior EFS. Furthermore, the PC-MRD response was not found to be significant over PI-MRD (P-value=0.17). ETP *vs* non-ETP status was also not found to be associated with EFS (P-value=0.85).

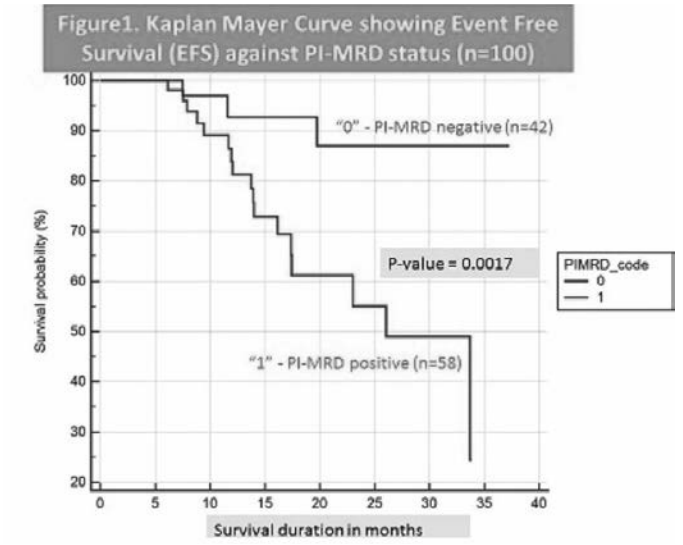

Figure 1.

Summary/Conclusions: We concluded that 10-color FC-based post-induction MRD response is a powerful indicator of EFS in childhood T-ALL. The frequency of PI-MRD positivity was significantly high in ETPALL indicating a lower tumor clearance rate. There was no difference in the EFS based on the level of PI-MRD-positivity indicating even a low level (<0.01%) PI-MRD is important in risk-stratification of childhood-TALL.

SMAC MIMETICS - A NOVEL THERAPEUTIC APPROACH IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Meyer[1,*], J. Zinngrebe[1], L.-H. Meyer[1], K.-M. Debatin[1]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Background: Pediatric acute lymphoblastic leukemia (ALL) is one of the most common malignancies in childhood. Survival rates have increased enormously over the past decades, but the prognosis for patients with relapsed ALL or ALL resistant to conventional chemotherapy remains poor. Thus, novel therapeutic options are urgently required. The family of inhibitor of apoptosis proteins (IAPs) has been shown to play an important role in the prevention of cell death, and to mediate gene activation important for cell survival. Many of the cellular processes regulated by IAPs are deregulated in cancer. Thus, IAPs represent a promising target in anticancer therapy. IAP antagonists, also known as Smac Mimetics (SMs), were developed to counteract IAPs' function. SMs have been shown to induce cell death in a number of different cancer entities, amongst them B cell precursor (BCP)-ALL. In BCP-ALL, SM-induced cell death was

shown to depend on autocrine TNF secretion. Of note, only a subset of BCP-ALL cell lines and primografts showed sensitivity to SM treatment. Little is known about the underlying molecular mechanisms conferring resistance to SM treatment.
Aims: Evaluation of the efficacy of different SMs in inducing cell death in BCP-ALL and T-ALL cell lines. Identification of the underlying molecular resistance mechanisms to SM treatment in BCP-ALL and T-ALL cell lines.
Methods: Cell death induced by SMs AT406 (Debiopharm Int.), LCL161 (Novartis), Birinapant (Medivir) and BV6 (Genentech) was evaluated by FSC/SSC in the BCP-ALL cell lines Nalm6, Reh, UoCB6 and RS4;11 and in the T-ALL cell lines ALL-SIL, CEM, Jurkat and Molt4. Expression of cellular inhibitor of apoptosis proteins (cIAPs) 1/2 and X-linked inhibitor of apoptosis protein (XIAP) in presence and absence of different SMs was assessed in the above-named cell lines by Western blot. The mode of cell death was assessed using inhibitors of Caspase activity (zVAD) and receptor-interacting protein 1 kinase (RIP1K) activity (Nec-1). Dependency of SM-induced cell death on TNF secretion was assessed by application of Etanercept, a TNFR2-Fc fusion protein.
Results: BCP-ALL cell lines Reh and UoCB6 and T-ALL cell lines ALL-SIL and CEM were identified to be sensitive to SM-induced cell death with half maximal inhibitory concentration (IC50) values below 1 micromolar. Interestingly, we found that the bivalent SMs Birinapant and BV6 are up to 100x more effective in killing ALL cell lines than the monovalent SMs AT406 and LCL161. SM treatment resulted in efficient and rapid degradation of cIAP1 and 2 in both, sensitive and resistant cell lines. Interestingly, all tested SMs were equally efficient in degrading cIAPs indicating that the resistance mechanisms are likely to be downstream of cIAPs. Next, we assessed the mode of SM-induced cell death in the sensitive cell lines by using zVAD or Nec-1 in order to block activity of Caspases or RIP1K, respectively. These experiments showed that Reh and UoCB6 cells die by apoptosis whilst CEM cells die by necroptosis upon stimulation with SMs. SM-induced cell death in ALL-SIL cells was neither blocked by zVAD nor Nec-1 nor the combination thereof. These results are substantiated by the fact that SM treatment induced typical hallmarks of apoptosis, *i.e.* cleavage of Poly-(ADP-ribose-)Polymerase (PARP), Caspase 8 and 3, in the SM-sensitive BCP-ALL cell lines whereas no Caspase cleavage was detectable in the sensitive T-ALL cell lines following stimulation with different SMs. In addition, the bivalent SMs BV6 and Birinapant more effectively induced cleavage of PARP and Caspases than the monovalent SMs in Reh and UoCB6 cells. In addition, we found that SM-induced cell death in Reh and UoCB6 cells is partially dependent on autocrine TNF-secretion. Interestingly, we identified ALL-SIL cells to die in a TNF-dependent manner, whilst CEM cells die independently of TNF. This strongly suggests that TNF is not the only driver of SM-induced cell death in ALL cells.
Summary/Conclusions: We identified a subset of both, BCP- and T-ALL cell lines to be sensitive to SM-induced cell death with IC50 values below 1 micromolar. Monovalent SMs are less effective than bivalent SMs in killing ALL cell lines. SMs induce differential modes of cell death with a variable dependency on autocrine TNF secretion in the sensitive ALL cell lines. In-depth molecular characterization of resistance mechanisms of ALL cells to SM-induced cell death is required to identify patients that will benefit from a SM-based treatment regimen.

E839

SINGLE-AGENT MOR208 IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL): A SINGLE-ARM PHASE II STUDY

R. Klisovic[1,*], M. Winderlich[2], S. Ambarkhane[2], E. Jabbour[3]
[1]Department of Internal Medicine, Division of Hematology & Oncology, The Ohio State University, Columbus, OH, United States, [2]MorphoSys AG, Planegg, Germany, [3]Department of Leukemia, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: CD19 is a type I transmembrane glycoprotein that is expressed throughout B-cell development until terminal plasma cell differentiation. CD19 is also broadly and homogeneously expressed across different B-cell malignancies, including B-ALL. MOR208 is a CD19 monoclonal antibody with an enhanced Fc region, which leads to a potentiation of antigen-dependent cell-mediated cytotoxicity and antigen-dependent cell-mediated phagocytosis.
Aims: To investigate the efficacy and safety of single-agent MOR208 in the treatment of patients with R/R B-ALL.
Methods: This is a single-arm phase II study of MOR208 in patients aged ≥16 years with histologically confirmed R/R B-ALL with progression after at least one prior therapy. Patients with Philadelphia-chromosome-positive (Ph^+) B-ALL could be included only if they were intolerant or refractory to at least one tyrosine kinase inhibitor. MOR208 was administered at 12mg/kg IV, weekly, over two 28-day cycles, with a loading dose on day 4 of cycle 1. Patients with a partial response (PR) could receive a further 2 cycles of MOR208; patients with a complete response (CR) or CR with incomplete count recovery (CRi) after 2–4 cycles could receive extended MOR208 therapy until progression. The primary endpoint was the overall response rate. The trial was prematurely terminated due to insufficient evidence of single-agent activity leading to slow recruitment.
Results: 22 patients were enrolled; median age was 52 years (range 16–79), 12 (55%) patients were male, 6 (27%) patients had previously received an allogeneic stem cell transplant (SCT), the most common disease subtype was pre-B-ALL (15, 68%) and 2 (9%) patients had Ph^+ B-ALL. 6 (27%) patients received ≥2 cycles of MOR208 and had a subsequent response assessment. Responses were seen in 2 patients; and included a CR and a CRi, giving an overall response rate of 9%. These 2 patients received extended MOR208 treatment. A further 3 (14%) patients did not fulfil the criteria for PR but did not progress; 16 (73%) patients withdrew before completing cycle 2, in most cases due to progressive disease (PD). The patient in CR met the criteria for allogeneic SCT, but declined this at the time; response duration was 8 weeks, with subsequent PD. The patient with the CRi had a response duration of at least 4 weeks, but discontinued due to a treatment-emergent adverse event (TEAE), sclerosing cholangitis. For 12 out of 13 patients with available data, MOR208 treatment led to a rapid reduction in blast/B-cell counts in the peripheral blood; in most cases a reduction of >90% within 1 week of treatment initiation was seen (bone marrow counts were not available). The most common grade ≥3 TEAEs were febrile neutropenia, thrombocytopenia, neutropenia, sepsis and hyperglycemia (each 5 [23%] patients). Infusion-related reactions were reported in 13 (59%) patients; all occurred on day 1 of cycle 1 and were mostly grade 1 or 2, with one grade 3 event; all patients recovered on the same day. Pharmacokinetic data were comparable with previous clinical studies and anti-MOR208 antibodies were not detected.
Summary/Conclusions: MOR208 showed signs of clinical efficacy with rapid reductions in peripheral blood blasts in most patients with R/R B-ALL, but the durability and frequency of achieving CRs was suboptimal, which was not unexpected given the complexity of R/R B-ALL. However, since the safety profile of MOR208 was consistent with previous studies and favorable, further development as a part of a combination treatment in R/R B-ALL remains a promising approach.

E840

UPDATED RESULTS FROM ZUMA-4: A PHASE 1/2 STUDY OF KTE-C19 CHIMERIC ANTIGEN RECEPTOR (CAR) T CELL THERAPY IN PEDIATRIC AND ADOLESCENT PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

D.W. Lee[1,*], A.S. Wayne[2], V. Huynh[3], R. Handgretinger[4], P.A. Brown[5], R. Pieters[6], A.C. Dietz[2], M.A. Pulsipher[2], J. Rossi[7], A. Mardiros[7], Y. Jiang[7], L. Navale[7], J. Aycock[7], S. Stout[7], J. Wiezorek[7], R. Jain[7]
[1]Division of Pediatric Hematology/Oncology, Department of Pediatrics, University of Virginia, Charlottesville, [2]Children's Center for Cancer and Blood Diseases, Division of Hematology, Oncology and Blood and Marrow Transplantation, Children's Hospital Los Angeles, USC-Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, [3]Division of Oncology, Blood and Marrow Program, CHOC Children's Hospital, Orange, United States, [4]Department of Pediatric Hematology and Oncology, University Children's Hospital, Eberhard Karls University, Tuebingen, Germany, [5]Pediatric Leukemia Program, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, United States, [6]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands, [7]Kite Pharma, Santa Monica, United States

Background: Acute lymphoblastic leukemia (ALL) exhibits a bimodal age distribution with 60% of cases occurring in children and adolescents (<20 y) and 25% in older adults (>45 y; http://seer.cancer.gov/csr/1975_2013/) and is the most common childhood malignancy (*Hematol Rep* 2014;6:5554; *Front Oncol* 2014;4:63). ALL has an incidence of 1.2 to 1.4 per 100,000 per year in Europe (*BMC Cancer* 2015;15:771). As many as 20% of children relapse after initial therapy, with subsequent poor clinical outcomes (*Front Oncol* 2014;4:63). Promising results were observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in B cell malignancies, including refractory, aggressive non-Hodgkin's lymphoma in the ZUMA-1 trial (*Blood* 2016;128:LBA-6). Here, we present updated results from the phase 1 portion of ZUMA-4, a phase 1/2 trial of KTE-C19 in pediatric and adolescent patients with relapsed/refractory (R/R) ALL.
Aims: The aim of the phase 1 study is to evaluate the safety of KTE-C19 in pediatric and adolescent patients with R/R ALL.
Methods: Pediatric and adolescent patients (aged 2-21 y) with high burden R/R ALL (>25% marrow blasts), adequate renal, hepatic, pulmonary and cardiac function received 2×10^6 CAR T cells/kg after low-dose conditioning chemotherapy consisting of cyclophosphamide (900mg/m^2 once) and fludarabine (25mg/m^2/d for 3 days) (CyFlu). The primary endpoint of phase 1 is the incidence of dose-limiting toxicities. Secondary endpoints include efficacy outcomes and biomarker assessments.
Results: As of 19 Jan 2017, 5 patients have enrolled and 4 have been treated with KTE-C19 at 2×10^6 CAR T cells/kg. KTE-C19 was successfully manufactured in a centralized, streamlined 6-8-day process for all patients across a range of baseline absolute lymphocyte counts ($0.21–1.0\times10^9$/L) except in 1 patient who had disease progression with white blood cells 150,000/µL at apheresis and <0.2% T cells in the apheresis collection. All 4 treated patients had high disease burden with a median marrow lymphoblast content of 57%

(range, 41–99%). All 4 patients received bridging chemotherapy during the manufacturing period before conditioning chemotherapy and KTE-C19. No patient experienced a dose-limiting toxicity. One patient had a grade 5 adverse event of disseminated mucormycosis which was not related to KTE-C19. Cytokine release syndrome was reported in all 4 patients (all ≤ grade 3); neurologic events were reported in 1 patient (grade 3). All cytokine release syndrome events resolved with tocilizumab, corticosteroids, and/or siltuximab plus other supportive care with a median duration of 8.5 (range, 4-16) days. Minimal residual disease-negative remission was observed in all 4 patients. One patient received stem cell transplant post-remission, which is allowed per protocol at investigator discretion. Peak expansion of CAR T cells occurred 1-2 weeks post-KTE-C19 infusion. Updated data with additional patients, different dose of KTE-C19, earlier tocilizumb use, and biomarkers will be presented.

Summary/Conclusions: KTE-C19 after low-dose CyFlu has been tolerable and appears safe for further analysis in pediatric and adolescent patients with R/R ALL. No dose-limiting toxicities were observed with KTE-C19 at the 2×10^6 cells/kg dose in patients despite high leukemic burden. All patients receiving KTE-C19 achieved a minimal residual disease-negative remission. Based on these results, ZUMA-4 continues to enroll (NCT02625480).

E841

COMPARISON OF 8-COLOR FLOW CYTOMETRY AND PCR-BASED METHODS IN MEASUREMENT OF MINIMAL RESIDUAL DISEASE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

S. Hrabovsky[1,2,*], F. Folber[1,2], J. Horacek[3,4], O. Stehlikova[1], H. Jelinkova[1], C. Salek[5,6], M. Doubek[1,2,7]

[1]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, [2]Faculty of Medicine, Masaryk University, Brno, [3]4th Department of Internal Medicine – Hematology, University Hospital and Charles University, Faculty of Medicine Hradec Kralove, [4]Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences, Hradec Kralove, [5]Institute of Hematology and Blood Transfusion, [6]First Faculty of Medicine, Charles University, Prague, [7]Central European Institute of Technology, Brno, Czech Republic

Background: The presence of minimal residual disease (MRD) is the most important prognostic factor in adult acute lymphoblastic leukemia (ALL). MRD monitoring is routinely performed by flow cytometry (FCM) and real-time quantitative polymerase chain reaction methods (RQ-PCR).

Aims: We conducted a retrospective analysis comparing these MRD measurement methods in ALL patients treated in three Czech hematology/oncology centers within the CELL group (Czech Leukemia Study Group for Life).

Methods: Adult patients (age 18-55) with both Ph-negative and positive ALL were enrolled in the study, all treated consecutively between 2008 and 2016 according to a pediatric-inspired CELL ALL protocol. Samples for MRD evaluation were acquired from bone marrow on day 26 of induction (D26) and in the 11th week of treatment before the first consolidation (W11). We divided RQ-PCR MRD positive and negative groups using three different cut-off values and analyzed them separately: 1) 1.0×10^{-3}, 2) 1.0×10^{-4}, 3) every RQ-PCR positive result considered MRD positive even below 1.0×10^{-4}. Cut-off value 1.0×10^{-3} was used for FCM MRD. Results were statistically analyzed by the Kaplan-Meier method and log-rank (Cox-Mantel) test.

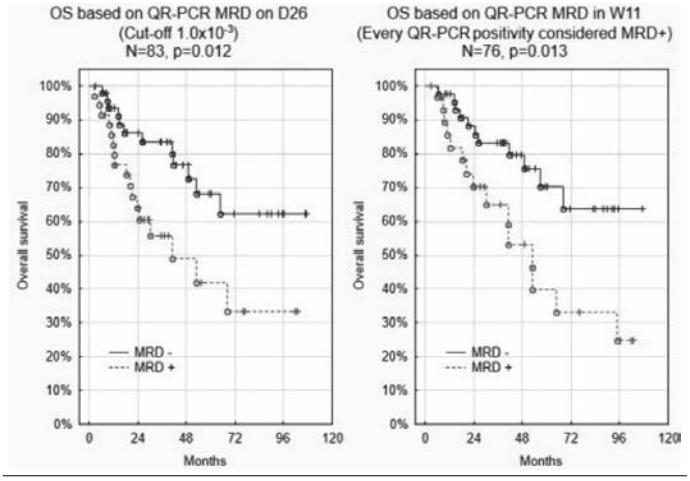

Figure 1.

Results: Total number of 103 patients was evaluated. Nine of them (8.7%) who did not reach a hematological remission on D26 were excluded from the study. The median follow-up of the final cohort was 36.9 months. MRD evaluation was carried out by 8-color FCM (N=73) and RQ-PCR of immunoglobulin heavy chain (IgVH, N=62) or T-cell receptor (TCR, N=3) clonal rearrangements and BCR-ABL (N=24), MLL-AF4 (N=4) and E2A-PBX1 (N=1) fusion genes. Methods with strongest sensitivity for OS prediction on D26 were RQ-PCR with 1.0×10^{-3} cut-off (4-year OS: 76.6% *vs* 48.8%; median OS: not reached *vs* 39.1 months; p=0.012) and FCM (4-year OS: 78.3% *vs* 30.3%; median OS: not reached *vs* 27.4 months; p=0.016). The most sensitive method in W11 was RQ-PCR with every positive result considered MRD positive (4-year OS: 79.6% *vs* 53.1%; median OS: not reached *vs* 46.5 months; p=0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RQ-PCR (p<0.01).

Summary/Conclusions: Our analysis has shown both RQ-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients receiving an intensive treatment. Furthermore it seems convenient to take any RQ-PCR positivity (even below 1.0×10^{-4}) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RQ-PCR as a method of choice for MRD assessment in adult ALL while reserving FCM as a backup method for patients without applicable RQ-PCR target or when faster MRD evaluation is needed.

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.

QUALITY-ADJUSTED LIFE YEARS (QALY) FOR INOTUZUMAB OZOGAMICIN *VS* STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL)

I. van Oostrum[1,*], Y. Su[2], B. Heeg[1], T. Wilke[3], A. Smith[4], F.R. Loberiza[2]

[1]Ingress-health Netherlands, Rotterdam, Netherlands, [2]Pfizer Inc, New York, United States, [3]Ingress-health Germany, Wismar, Germany, [4]Pfizer, Ltd, Walton Oaks, United Kingdom

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior clinical activity *versus* standard of care (SOC; intensive chemotherapy), including clinically meaningful improvement in overall survival (OS), high rates of complete remission (CR) and potentially curative hematopoietic stem cell transplantation (HSCT), and favorable patient-reported outcomes for R/R ALL in the phase 3 INO-VATE trial. Quality of life (QoL) is an important consideration for R/R ALL patients in both short- and long-term survival.

Aims: This study aimed to estimate mean overall survival adjusted for QoL (QALY) for patients treated with InO *vs* SOC.

Methods: A Markov model was developed with five health states - No CR, CR, post-HSCT, progression, and death. Lengths and transition probabilities between health states and mortality rates were based on the InO-VATE trial. These rates were extrapolated to a lifetime horizon using parametric survival curves fitted to available OS data, and published literature for survival beyond available data. Utilities (QoL valuations) for each health state were based on the patient-reported EQ-5D scores collected in the InO-VATE trial and a literature review for health states not captured in the trial. Disutilities from adverse events experienced during and after treatments, including adverse events as a result of subsequent HSCT such as veno-occlusive disease (VOD), were taken into account in overall QoL. Outcomes were discounted at 1.5% and half-cycle corrected.

Results: The estimated mean LY and QALY in each health state for InO and SOC and their differences are shown in Table. Most gains in LY and QALY for InO over SOC were from Post-HSCT. These gains are greater in the InO arm as more patients achieved a CR and could undergo a HSCT. Additionally, a "tail-of-the-curve" survival gain Post-HSCT is observed in InO but not SOC.

Table 1.

	LY			QALY		
Health state	**InO**	**SOC**	**InO-SOC**	**InO**	**SOC**	**InO-SOC**
No CR	0.07	0.13	-0.06	0.05	0.08	-0.03
CR	0.25	0.09	0.17	0.19	0.07	0.12
Post HSCT	2.98	0.62	2.36	2.20	0.44	1.76
Progression	0.16	0.28	-0.12	0.05	0.08	-0.04
Total	*3.46*	*1.12*	*2.34*	*2.48*	*0.67*	*1.81*

**Increment values may not always correspond to differences between LYs and QALYs due to rounding*

Summary/Conclusions: This analysis taking into account both quantity and quality of life estimates shows that InO offers an average of nearly 2 more years of QALY compared to SOC in R/R ALL, based on higher CR and HSCT rates, "tail-of-the-curve" survival gains, and better QoL. This can help inform patients, physicians and payers in decision making.

E843

A COST-EFFECTIVE, HIGH SENSITIVITY 10-COLOR SINGLE TUBE FLOW-CYTOMETRY BASED B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA MINIMAL RESIDUAL DISEASE (MRD) ASSAY WITH STUDY OF ARTIFACTS AND MIMICS

G. Chatterjee[1,*], D. Dhaliwal[1], S. Ghogale[1], B. Yajamanam[1], N. Deshpande[1],

S. Kedia[1], P. Rodrigues[1], A. Kumar[1], S. Gujral[1], N. Patkar[1], P. Subramanian[1], P. Tembhare[1]
[1]Hematopathology, Tata Memorial Hospital, Mumbai, Mumbai, India

Background: Minimal residual disease (MRD) has been proven to be the most important indicator of relapse in BCPALL. Recently, flow-cytometry based MRD has been shown to achieve a sensitivity of $<10^{-5}$ using a standardised panel with high number of event acquisition. However, high-sensitivity BMRD analysis is based on experience and acquisition of high number of events also includes other rare BM cellular elements and artifacts.We present a study of the cost-effective high-sensitivity 10-color single tube FC-MRD assay in BCPALL along with description of rare BM cellular elements and artifacts causing interference in analysis.
Aims: 1. To study the applicability and sensitivity of a 10-color high event single tube FC-MRD assay for BCPALL; 2. To document the rare BM cellular elements and artifacts causing interference in high-sensitivity FC-MRD assay for BCPALL and describe their prevalence and immunophenotypic features.
Methods: We studied 230 BCPALL MRD samples.FC-immunophenotyping was performed on Navios flow-cytometer using bulk-lysis-and-stain method and data was analyzed with Kaluza-software. MRD was monitored using 10-color single tube FC-MRD assay including CD45, CD10, CD19, CD20, CD34, CD38, CD58, CD86, CD123 and CD25/CD73 with an additional 4-color nuclear-dye (SYTO13) tube. Samples with cluster of ≥20 and ≥2 leukemia associated phenotypes (LAIPs) were called MRD-positive. High number of events were acquired for MRD-assay (1.5 to 6 million). To evaluate the applicability of assay, number of LAIPs were determined in diagnostic and MRD samples. In addition, the frequency and antigen expression pattern of mimics and artifacts were studied.
Results: We studied 230 BCPALL MRD samples. High number of events was acquired for MRD-assay with median-events 3427000 (range, 1678000 to 6052800). We determined the limit of detection (LOD=10 events) and limit of quantitation (LOQ=30 events) by performing dilution assay. MRD was positive in 107 (46.5%) samples with median of 0.135% and range of 0.0003% to 48.3%. We categorized positive MRD results into samples with MRD <0.001%,0.001- <0.01%, 0.01- <0.1%, 0.1- <1.0% and >1% and they were respectively 1.74%, 10.43%, 13.48%, 5.65% and 10.00%. Furthermore, in 24 samples with MRD-positive ≤0.01% and >1.5 million acquired-events, the results were compared between time-gated initial 500000-events, 1000000 events and all events acquired. Sixteen samples among these were found to be negative in initial 500000-events and eight in initial 1000000-events highlighting the importance of acquisition of >1.5 million cells. Further, we categorized different rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal stromal/stem cells and endothelial cells; 4) CD123+ CD19+ ?PDC precursors; 5) CD86+ CD58+ B cell precursors (BCP); 6) CD19+ NK cells **(Table 1)**. We also described their immunophenotypic features highlighting the differentiating features from MRD and B cell precursors **(Figure 1)**.

Table 1.

	34+ mature B	10+ mature B	73+ mesenchymal cells	123+ 19+ ?PDC precursor	86+ 58+ BCPs	19+ NK cells
Mean	0.192	0.238	0.161	0.159	0.254	7.404
Median	0.100	0.105	0.080	0.100	0.145	2.900
Range	0.008-1.2	0.01-0.8	0.001-1.4	0.0001-.8	0.01-0.9	0.1-32.7

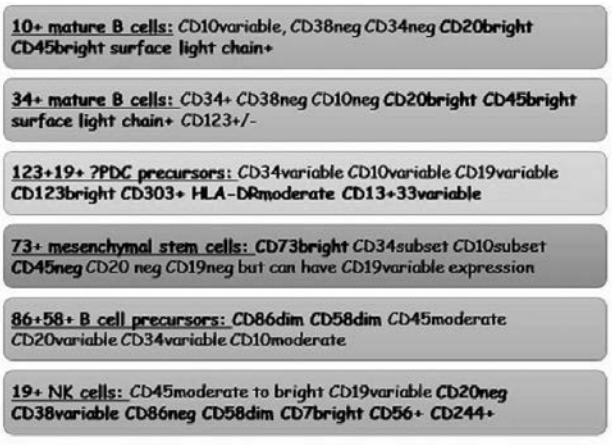

Figure 1.

Summary/Conclusions: We established a cost-effective 10 color single tube FC-MRD assay with high sensitivity ofatleast 1 in 10^5 and applicability in >97% BCPALL MRD samples. We also described the frequency and extent of different cellular events and artifacts that can interfere with high-sensitivity BCPALL FC-MRD analysis. The knowledge regarding presence and antigen expression pattern of these cellular events and artifacts are critical to avoid potential false positive results.

E844

SPECKLE TRACKING ECHOCARDIOGRAPHY IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: A PRELIMINARY STUDY

M. Belloni[1,*], G. Biddeci[1], G. Bordin[2], E. Varotto[1], M. Pillon[1], G. Geranio[1], G. Basso[1], B. Buldini[1], A. Todesco[1], B. Castaldi[2], M.C. Putti[1]
[1]Clinic of Pediatric Hemato-Oncology - Department of Woman and Child Health, [2]Pediatric Cardiology Unit - Department of Woman and Child Health, University of Padua, Padova, Italy

Background: Children with acute lymphoblastic leukemia (ALL) are at risk for late-onset anthracycline-related cardiotoxicity. Left ventricular Global Longitudinal Strain (GLS) by Speckle Tracking Echocardiography has been recently used to identify preclinical late-onset heart failure in both adult and pediatric ALL patients. Nonetheless, efficient strategies for the early diagnosis and management of cardiac toxicity during chemotherapy are still not defined.
Aims: We prospectively studied LV function in ALL patients treated at our Centre, according to AIEOP-BMF ALL 2009 protocol, measuring both GLS and M-Mode Left Ventricular Ejection Fraction (LVEF).
Methods: Out of 42 consecutively examined ALL patiets (pts), 32 (76%) underwent prospective follow-up (*Table*). At basal evaluaton, 19 pts had Hb<9 g/dl, 7 pts had fever, 7 pts had hyperleukocytosis, 2 had BMI>25. The influence of there factors on cardiological parameters could not be evaluated due to low numbers. Echocardiography was performed with Vivid E9 ultrasound system (GE Medical System) and M5Sc probes at the following time points (TP): diagnosis (TP0), after induction phase (anthracycline cumulative dose 120mg/m^2, TP120), at the end of anthracycline exposure (TP240 in standard risk-SR-pts; TP320 in high risk-HR-pts). HR pts underwent intermediate controls before each re-exposure (TP150, TP210, TP270). GLS values>-19% (or GLS drop >15% from basal value) and LVEF values<55% (or LVEF drop >10% from basal value) were considered as abnormal. Statistical analysis was performed using Student's t-test.

Table 1.

A. Main features of SR/HR ALL patients

	SR n^ 26 pts		HR n^ 16 pts
Gender M/F	16/10		12/4
Age	6 (2-16)		13 (4-18)
Phenotype B/T	24/2		12/4

B. Patients with LFVE and/or GLS alteration at different TP

SR	TP0 n^ 26	TP120 n^ 10	TP240 n^ 11	
GLS	3 (11,5%)	3 (30%)	0	
LVEF	0	2 (20%)	0	

HR	TP0 n^ 16	TP120 n^11	TP150 n^ 10	TP210-270 n^ 6	TP320 n^5
GLS	0	7 (63,6%)	6 (60%)	1 (16,7%)	0
LVEF	0	1 (9%)	4 (40%)	1 (16,7%)	0

Results: Basal evaluation was performed on 26 SR and 16 HR pts. Three SR pts with severe anemia (<7g/dl) and/or BMI>25 showed altered GLS at TP0. At the succeeding evaluation, 2 patients recovered, while one obese adolescent confirmed GLS and LVEF alterations. Follow-up after induction therapy (TP120) was performed on 10 SR pts and on 11 HR pts: GLS was altered in 3/10 SR pts (30%) and in 7/11 HR pts (63.6%). Two SR pts showed alterations in both GLS and LVEF values, while one child had isolated GLS impairment. Out of the 7 HR pts, one had both GLS and LVEF impairment and 3 worsened in LVEF at TP150. The 3 remaining HR pts subsequently recovered in GLS value. In 2 additional HR pts both GLS and LVEF were altered at a late evaluation (TP150, TP270). After the induction phase, we found an early 10% increase in mean GLS value (p=0,002), while mean LVEF value was reduced only by 6% (p=0,052), a non-significant difference even by clinical criteria. Thus, according to the recent literature, the combination of GLS and LVEF demonstrated to be able to identify children at risk for LV impairment, as proved later by LVEF fall in 5 cases. Globally, 12 (37%) pts showed GLS impairment at different TP. After the induction therapy, 2/10 SR (20%) and 6/11 HR (54%) pts were considered having significant LV function impairment, even if not clinically evident yet. In 4 patients with GLS impairment, the LVEF never reached pathological values. Eight patients underwent cardiological therapy. We chose to treat them

with b-blockers, as they could limit anthracycline toxicity by their heart rate-lowering activity and antioxidant effect. All the 8 patients subsequently improved in both GLS and LVEF values, despite the occurrence of one episode of mild hypotension in 2 patients.
Summary/Conclusions: ALL children, even if exposed to low doses of anthracycline, show early signs of LV impairment. Overt drop in LVEF, when present, mostly follow GLS alterations. Alterations seem more frequent in HR pts, possibly due to the higher burden of both leukemia itself and HR treatment. Further studies on wider series are needed to confirm the relevance of the early diagnosis of LV preclinical dysfunction in pediatric ALL patients.

E845

NUDT15 VARIANT CAUSING HEMATOPOIETIC TOXICITY WITH LOW 6-TGN LEVEL IN KOREAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

H. Hoe Koo[1,*], E. Sang Yi[2], Y. Bae Choi[3], N. Hee Lee[4], J. Won Lee[1], K. Hee Yoo[1], K. Woong Sung[1], R. Choi[5], S.-Y. Lee[5]
1Pediatrics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, 2Department of Pediatrics, Korea University Guro Hospital, Korea University College of Medicine, 3Department of Pediatrics, Chung-Ang University Hospital, Seoul, 4Department of Pediatrics, Cha Bundang Medical Centre, Cha University, Seongnam, 5Department of Laboratory Medicine and Genetics, Sungkyunkwan Univ School of Medicine, Samsung Medical Center, Seoul, Korea, Republic Of

Background: *NUDT15* polymorphism has been recently identified as a determinant of thiopurine intolerance. 6-thioguanine nucleotides (6-TGN) is monitored to prevent hematopoietic toxicity in acute lymphoblastic leukemia (ALL).
Aims: This study intended to evaluate the impact of *NUDT15* polymorphism on thiopurine intolerance and 6-TGN level in Korean children with ALL.
Methods: Genotyping of *NUDT15* was performed in 258 children with ALL who were registered in Samsung Medical Center. According to *NUDT15* diplotype, patients were classified into low risk (LR, wild-type), intermediate risk (IR, heterozygous variant), or high risk (HR, homozygous or compound heterozygous variant). Total of 182 were fianlly included after 76 patients were excluded for *TPMT* variation or lack of information during maintenance therapy; LR (n=131), IR (n=46), and HR (n=5).
Results: The least 6-mercaptopurine (6-MP) dose (mg/m^2/day) were administered in HR (HR 8.9 vs. IR 25.9 vs. LR 31.8, p<0.01). HR experienced the longest days of therapy interruption (HR 167 *vs* IR 30 *vs* 15, p<0.01) and days of leukopenia (HR 131 *vs* IR 92 *vs* LR 59, p<0.01). The lowest WBC and platelet counts and hemoglobin level were observed in HR. 6-TGN level (pmole/8x10^8 RBC) divided by 6-MP dose (mg/m^2) was the lowest in HR group (HR 4.4 *vs*. IR 13.3 *vs* HR 14.7, p<0.01).
Summary/Conclusions: Patients with *NUDT15* variants encountered significant thiopurine intolerance even with low level of 6-TGN. This concurs with the existing hypothesis that NUDT15 protein may prevent incorporation of thiopurine active metabolites into DNA. Therefore 6-TGN monitoring is not useful to predict hematopoietic toxicity for patients with *NUDT15* variant.

E846

USING NEXT GENERATION SEQUENCING TO DETECT CLONAL TRG AND TRB GENE REARRANGEMENTS

P. Shah[1,*], Y. Huang[1], K. Hutt[1], T. Stenzel[1], J.E. Miller[1]
[1]Invivoscribe Technologies, Inc., San Diego, United States

Background: During early T-cell development, somatic rearrangements occur within T cell receptor beta (*TRB*) locus that bring together, sequentially, the joining of D and J gene segments, followed by joining of a V segment to the DJ pair. This process of random combinatorial selection, coupled with N-region diversity, generates rearrangements that are unique in both length and sequence. Since T cell malignancies arise from transformation and clonal expansion of a single cell, over-represented *TRB* rearrangements can be readily identified, in the majority of alpha-beta T cell malignancies. The T cell receptor gamma (*TRG)* locus rearranges prior to *TRB*, combined use of *TRG* + *TRB* assays identify the vast majority of T-cell, as well as some B-cell malignancies. The current gold standard for identifying these clonal rearrangements is to use PCR assays to amplify all rearrangements, and then identify clonal products on the basis of their uniform size following size separation using capillary electrophoresis (CE). These PCR-CE assays are quite sensitive, but they provide limited information; most notably they don't identify the sequence information required to allow tracking of residual disease during the course of treatment. Recently, next-generation sequencing (NGS) based approaches for immune receptor genes have been developed to both improve the sensitivity of clonal detection and identify the specific V-(D-)J DNA sequences required to track clones in follow-up testing. We have developed such an NGS-based *TRG* + *TRB* clonality assay formatted for the Illumina® MiSeq® platform.
Aims: To develop an NGS-based *TRG* + *TRB* clonality assay for the MiSeq® platform.
Methods: Rearranged products from within the *TRG* and *TRB* locus were generated by PCR using proprietary multiplex master mixes with consensus primers targeting all *TRG* and *TRB* V and J exon families, synthesized with MiSeq specific adapter and individual barcode ID sequences. The PCR products were purified, quantified and pooled into equimolar library. The final library was sequenced on the MiSeq. The sequencing data FASTAQ output file was analyzed using Invivoscribe's LymphoTrack® software. The software generated frequency distributions for the top 200 rearranged sequences, identified the DNA sequences, generated V-J assignments and V-J usage. Cell line DNA known *TRG* and *TRB* V-J rearrangements was tested for the analytical performance. DNA from different clinical sample type (FFPE, PB, and BM) was used to assess the clinical performance.
Results: This NGS assay was able to correctly detect all known *TRB* and *TRG* rearrangements from cell line DNA. The on-target reads per sample were 90% - 100%. Excellent linearity (R^2>0.90), sensitivity of 2.5% for clonality, and reproducibility (<20% CV) were demonstrated with serial dilutions of contrived cell line DNA. The clinical performance of the LymphoTrack® *TRG* + *TRB* NGS assays was evaluated on different clinical samples that have also been tested using the PCR-CE *TRG* and *TRB* assays. Assessment of clonality using the LymphoTrack® MiSeq and PCR-CE assays for *TRG* and *TRB* demonstrated good concordance.
Summary/Conclusions: This combo NGS assay provides a fast, simple, and accurate method to detect clonality. In combination with the LymphoTrack software, the *TRG* +*TRB* MiSeq assay can identify clonal *TRG* and *TRB* V(-D)-J rearrangements and the specific V(-D)-J region DNA sequences required to track clones in follow-up testing. Excellent clinical concordance in detecting clonality with specific rearrangements was demonstrated between LymphoTrack® MiSeq and PCR-CE method.

E847

DETECTION OF CLONALITY IN CLINICAL SPECIMENS FROM SUSPECTED B-CELL MALIGNANCIES USING COMPREHENSIVE IGH LYMPHOTRACK® MISEQ® AND PGM® ASSAYS

Y. Huang[1,*], K. Hutt[1], J. Panganiban[1], A. Jacobsen[1], N. Wong[1], D. Duong[1], R. Bob[2], S.A. Pileri[3], L. Bernard[3], E. Gerbino[3], T. Stenzel[1], J.E. Miller[1]
[1]Invivoscribe Technologies, San Diego, United States, [2]Institute for Pathodiagnostik, Berlin, Germany, [3]Haematopathology Unit at European Institute of Oncology, Milan, Italy

Background: PCR-based capillary electrophoresis (PCR-CE) methods targeting immunoglobulin heavy chain (*IGH*) framework 1, 2, 3 (FR1, FR2, FR3), and joining regions (J) are the current gold standard for clonality testing in suspected B-cell malignancies. Recently, next-generation sequencing (NGS) based approaches for immune receptor genes have been developed that improve sensitivity and identify the specific V-(D-)J DNA sequences required to track clones in follow-up testing. We developed comprehensive LymphoTrack® *IGH* (FR1, FR2, & FR3) Assays for both the Illumina® MiSeq® and ThermoFisher Scientific® Ion PGM™ platforms, which detect the vast majority of rearrangements in a single NGS run. In this pilot study, we compared the performance of both LymphoTrack® *IGH* MiSeq and PGM Assays to the *IGH* PCR-CE assay by testing in 59 anonymized, blinded clinical samples.
Aims: To assess the clinical performance of LymphoTrack® *IGH* MiSeq and PGM Assays
Methods: LymphoTrack® *IGH* Assay has been developed for both the MiSeq and PGM platforms. Proprietary consensus primers targeting the V and J gene segments of *IGH* were designed to include both platform specific adapter sequences and individual barcodes so multiple independent PCR products could be combined and sequenced together on the MiSeq or PGM platforms. MiSeq *IGH* FR master mixes were individually manufactured with 24 indices to allow analysis of 22 samples with 2 controls. PGM *IGH* FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. DNA was extracted from 21 PB, 37 FFPE and 1 BM clinical samples. Single step PCR amplification of 50 ng DNA input was followed by amplicon purification. Equimolar amounts of purified amplicons were pooled and loaded onto the MiSeq or PGM instruments. The sequencing data was analyzed using LymphoTrack® software, which first sorted the sequences by both index and framework region; then generated frequency distributions, V-J usage, identified specific sequences for top sequencing reads, and determined the somatic hypermutation rate of FR1 amplicons.
Results: The analytical performance of the LymphoTrack® *IGH* Assay on both NGS platforms was evaluated using dilutions of contrived samples with known V-J rearrangements. Both NGS assays demonstrated excellent linearity (R^2>0.90), sensitivity to detect 2.5% clonality, and reproducibility (<20% CV). The clinical performance of the LymphoTrack® *IGH* NGS assays was evaluated on 59 clinical samples that have also been tested using the PCR-CE *IGH* assay. Only samples that met the specimen and data acceptance criteria for both methods were evaluated to determine concordance. Assessment of clonality using the LymphoTrack® *IGH* MiSeq and PCR-CE assays demonstrated 95% (42/44) concordance. Concordance was 98% (40/41) comparing results tested using the LymphoTrack *IGH* PGM and PCR-CE assays. Concordance in clonality calls between the LymphoTrack® *IGH* PGM and MiSeq assays was 100% (51/51).

Summary/Conclusions: Comprehensive *IGH* Assays have been developed for both MiSeq and PGM platforms. These assays identify clonal *IGH* V-J rearrangements and provide the clonal DNA sequences of the tumor-specific clonotypes required to perform follow up testing to detect residual disease. Combining FR1, FR2 and FR3 improved the overall clonality detection rate to 96%. Both NGS-based *IGH* assays have demonstrated excellent concordance in detecting clonality regardless of whether clonality was determined using a PCR-CE method or with assays formatted for the MiSeq and PGM platforms.

E848

CORRELATION BETWEEN A 10-COLOR FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE (MRD) ANALYSIS AND MOLECULAR MRD IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

J. Singh[1,*], M. Gorniak[1], G. Grigoriadis[1,2], D. Westerman[3], M. McBean[3], N. Venn[4], R. Sutton[4], S. Morgan [1], S. Fleming[1,2]
[1]Laboratory Haematology, Alfred Pathology, [2]Clinical Haematology, Monash Health, [3]Pathology, Peter MacCallum Cancer Centre at the Victorian Comprehensive Cancer Centre, Melbourne, [4]Children's Cancer Institute, Lowy Cancer Research Centre, UNSW, Sydney, Australia

Background: Minimal residual disease (MRD) monitoring in Acute Lymphoblastic Leukemia (ALL) is an accepted standard of care in both adult and pediatric patients as one of the strongest predictive factors for disease outcome and as a stratification tool for treatment intensification and allogeneic stem cell transplant. The currently accepted standard of molecular monitoring with either immunoglobin heavy or kappa chain (IG) or T-cell receptor (TCR) quantitative PCR (qPCR) in Philadelphia negative ALL allows for sensitive monitoring of MRD, but requires a high degree of expertise, and factors such as cost and turnaround time may limit generalized applicability of this technique. Flow cytometric MRD monitoring is utilized in many centers, with increased sensitivity seen with implementation of multi-parameter flow cytometry at 8-colours or more.
Aims: We sought to compare a 10-color flow cytometry assay for detecting MRD in B-ALL with standard molecular monitoring.
Methods: To facilitate rapid identification of MRD in patients with B-ALL, we developed a 10-colour single tube flow cytometry assay utilizing CD19, CD22, CD20, CD38, CD58, CD13/33, CD66c, CD10, CD45 and CD34 as markers. These markers were selected to provide at least two targets for identification of B-lineage cells, and to include the most frequently aberrant markers in precursor B-lineage ALL. Samples were subject to bulk ammonium chloride lysis to maximize cell yields with a target of 1 x 10^6 events. Once normal maturation patterns were established, patient samples were analyzed in parallel to standard of care molecular monitoring with either IG/TCR qPCR in Philadelphia negative (Ph-) disease and *BCR-ABL* qRT-PCR in Philadelphia positive (Ph+) disease. Statistical correlation was performed in Graphpad Prism version 7.0 for linear regression and calculation of correlation co-efficient.

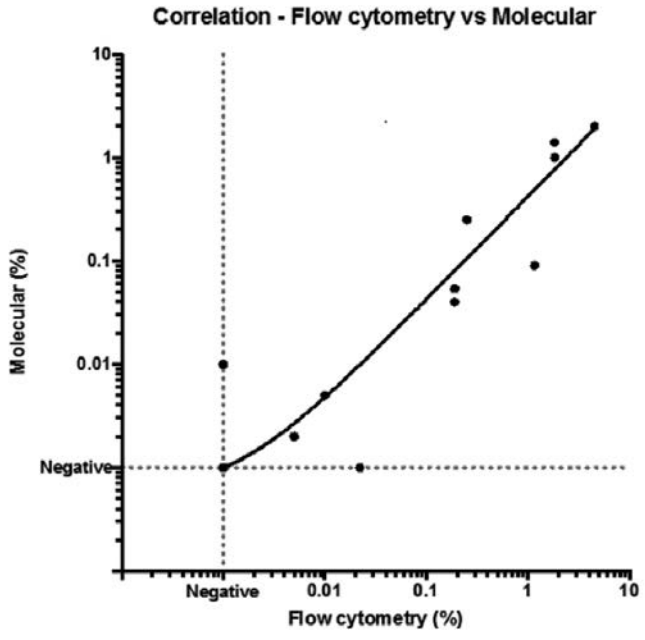

Figure 1.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of an identifiable marker. 24 samples from 13 patients were tested for MRD by flow cytometry. The median lower limit of detection was 0.0078% (range 0.0016% to 0.028%) with a median lower limit of quantification of 0.018% (range 0.002% to 0.07%). A sensitivity of <0.01% was attained in 21 of 24 samples (88%). 20 samples from 11 patients were tested concurrently for MRD by both molecular and flow cytometric methods. 11 samples were in Ph- disease and 9 were in Ph+ disease. MRD was detected by both molecular and flow cytometry in 11 samples and not detected by both methods in 8 samples. In one sample, MRD was detected only by molecular at an unquantifiable level. There was a strong correlation co-efficient between molecular and flow cytometric MRD analysis (R^2=0.905, p<0.001). Correlation was strong with both IG/TCR based molecular analysis (R^2=0.949, p<0.001) and *BCR-ABL* based molecular assays (R^2=0.993, p<0.001).
Summary/Conclusions: 10-color flow cytometric minimal residual disease analysis with bulk lysis attains a high degree of sensitivity in minimal residual disease determination in precursor B-lineage Acute Lymphoblastic Leukemia. There was a strong correlation with molecular MRD monitoring for both quantification of MRD and determination of MRD negative status. Flow cytometric methods may also permit MRD monitoring in patients where a suitable molecular assay cannot be developed.

E849

HYPOGLYCEMIC EVENTS DURING TREATMENT OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: OBSERVATIONS FROM TRIAL AIEOP-BFM ALL 2009

K. Bleckmann[1,*], J. Alten[1], N. Bodmer[2], E. Zapotocka[3], D. Barbaric[4], M. Schrappe[1], S. Vieth[1], M. Zimmermann[5], A. Möricke[1]
[1]Department of Pediatrics, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany, [2]Pediatric Oncology and Hematology, Universitäts-Kinderspital Zürich, Zürich, Switzerland, [3]Department of Pediatric Hematology and Oncology, Motol University Hospital, Prague, Czech Republic, [4]Centre for Children's Cancer and Blood Disorders, Sydney Children's Hospital, Sydney, Australia, [5]Pediatric Hematology/Oncology, Medical School Hannover, Hannover, Germany

Background: Hypoglycemia has been reported as a rare side effect in children and adolescents treated for acute lymphoblastic leukemia (ALL). It has been associated to purine nucleoside analogues (PNA), but potential relationship with asparaginase has also been described. Despite these reports, clinicians' awareness of this risk seems to be limited.
Aims: Descriptive evaluation of symptomatic hypoglycemic events during ALL treatment.
Methods: Hypoglycemic events were analyzed among 3293 patients treated in the trial AIEOP-BFM ALL 2009 in four of the participating countries (Germany, Switzerland, Czech Republic, and Australia) between 06/2010 and 08/2016. PNA were administered during induction-consolidation, the second part of the reintensification phase (reinduction-consolidation) and during maintenance (MT). Pegylated asparaginase (PEG-ASP) was given in induction, first part of reintensification, as well as high-risk blocks. Additionally, the benefit of intensified PEG-ASP was tested during induction-consolidation in the high-risk group, and during reinduction-consolidation/MT in the medium-risk group. Adverse events were generally captured in a targeted approach by means of defined events assessed as clinically relevant, not including hypoglycemia. Thus, data collection of these events was based on proactive reporting by the investigators. For analysis, clinical severity of the events was retrospectively graded according to patients' capacity of action and reaction.
Results: In total, 28 hypoglycemic events were reported in 26 of the 3293 patients. 25 events in 23 patients were described as symptomatic, to which further analysis was restricted (22 precursor B- and one T-ALL; 8 standard-risk, 12 medium-risk, and 3 high-risk). Age of patients ranged between 1.7 and 15.5 years at occurrence of symptomatic hypoglycemia. Balanced ratio between both sexes can be observed (13 male, 10 female), median age was essentially similar (male 3.2 y, female 4.1 y). Hypoglycemic events occurred in induction treatment (n=1), induction-consolidation (n=8), reinduction-consolidation (n=4; one in standard reinduction, 3 in reinduction with intensified PEG-ASP treatment), high-risk block (n=1), and in MT (n=11; 4 events during standard MT, 6 events during MT with intensified PEG-ASP treatment, and one event 4 weeks after last PEG-ASP during MT). Seven events were reported with mild symptoms, 6 patients showed moderate symptoms, and in 12 events patients showed severe symptoms (loss of consciousness, seizure-like).
Summary/Conclusions: In accordance with previous reports, hypoglycemic events accumulated in PNA containing treatment phases, but not exclusively. Considering that 324 patients of the total cohort were treated with intensified PEG-ASP in reinduction-consolidation/MT, an additive effect of PEG-ASP and PNA in triggering a hypoglycemic metabolic condition may be assumed although a similar effect was not seen in induction-consolidation with intensified PEG-ASP. However, numbers are small and reporting bias of the present data is probable, as hypoglycemic events were not captured systematically. Investigators' attention to adverse reactions and proactive reporting might be higher

in experimental arms as well as in case of preceding hypoglycemic events in other patients of the respective trial center. Despite these analytical limitations, our data suggest that hypoglycemia during ALL treatment is a relevant and probably underestimated clinical problem. Further investigation including possible identification of predisposing metabolic conditions is required to avoid harm to patients by this preventable complication.

E850

NUDT15 VARIANT IN KOREAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

S.Y. Park[1], Y.T. Lim[1], E.A. Kim[1], J.O. Hah[2], E.M. Choi[3], Y.J. Shim[3], H.S. Kim[3], J.-S. Ha[4], Y.K. Kim[5], J.M. Lee[1,*]
[1]Pediatrics, Yeungnam University, College of Medicine, [2]Pediatrics, Daegu Fatima Hospital, [3]Pediatrics, [4]Laboratory Medicine, Keimyung University School of Medicine and Dongsan Medical Center, [5]Laboratory Medicine, Yeungnam University, College of Medicine, Daegu, Korea, Republic Of

Background: Acute lymphoblastic leukemia (ALL) is the most prevalent pediatric cancer with cure rates approaching 90% with current therapy. Patient with ALL require long-term maintenance therapy. The combination of weekly methotrexate and daily 6-mercaptopurine (6-MP) consisted with the backbone of ALL maintenance regimens. Genetic polymorphism in thiopurine methyltransferase (TPMP) is well known to affect the 6-MP tolerance. However prevalence of non-function variant of TPMT is rare in Far East. Recently, a study has identified a variant of the *NUDT15* gene associated with intolerance of 6-MP.
Aims: We examined the association between NUDT15 polymorphism and clinical data of Korean pediatric ALL.
Methods: NUDT15 genotyping and collection of clinical data was performed for 74 Korean pediatric ALL patients from two different hospital. For NUDT15 genotyping, DNA was extracted from whole blood/or bone marrow sample and Sanger sequencing was performed for exon 1 and 3 of NUDT15 gene. 6-MP dose intensity, defined as the ration of prescribed 6-MP dose over protocol planned dose.
Results: We found two kinds of variants, c.55_56insGAGTCG(rs869320766) in exon 1 from 8 patients and c.415C>T(rs116855232) in exon 3 from 14 patients. Of them, 7 patients had both variants and all variants were heterozygote. Patients could be divided to four distinct groups according to combinations of genotype (Table 1). 6-MP dose intensity in wild type was higher than three other genotypes during maintenance therapy (p=0.003) (Fig 1). The number of hospitalized days in wild type is small compared to other three genotypes (p=0.017). Frequency of febrile neutropenia, hepatotoxicity, cumulative days of antibiotics use and overall survival did not significantly differ by NUDT15 genotype.

Table 1. Treatement outcome of children with acute lymphoblastic leukemia according to NUDT15 genotypes.

Genotype	Patient no	Relapse	Admission day during maintenance (days)	5-year EFS (%)	5-year OS (%)
Wild type	56	3(5.4%)	152.8 ± 94.7	96.4 ± 2.5	98.2 ± 1.8
w/c.415C>T	8	1(12.5%)	78.3 ± 62.8	87.5 ± 11.7	100.00
c.55_56insGAGTCG/c.415C>T	8	1(12.5%)	190.0 ± 85.2	100	100.00
c.55_56insGAGTCG/w	1	1(100%)	372	0	100.00

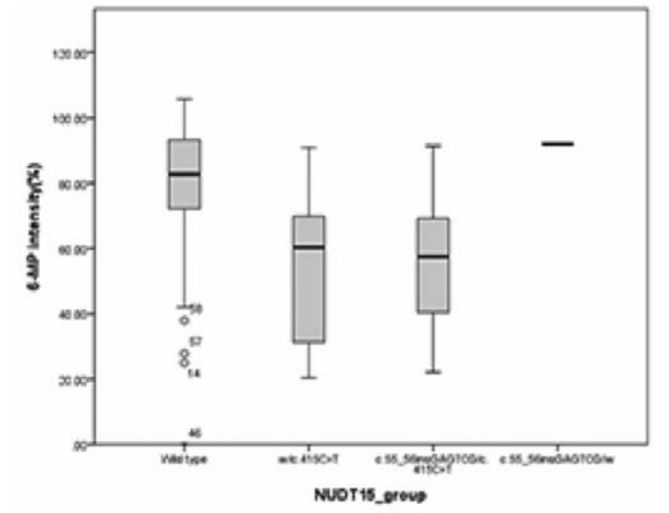

Figure 1.

Summary/Conclusions: Genotyping of *NUDT15* could be beneficial to predict the tolerable dose of 6-MP of pediatric ALL patients.

TREATMENT OUTCOME OF ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREAN ADOLESCENTS AND YOUNG ADULTS

H.Y. Ju[1], Y.A. Kim[2], D.H. Lee[2], K. Park[2], N.Y. Lee[2], H. Lee[3], B.-K. Park[1], H.J. Park[1,*]
[1]Center for Pediatric Oncology, [2]National Cancer Control Institute, [3]Hematologic Oncology Clinic, National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic Of

Background: The outcome of acute lymphoblastic leukemia (ALL) has markedly improved for last centuries, but the improvement was mainly observed in children under 10 years old. In contrast, the treatment outcomes of ALL in adolescents and young adults (AYA) still lag beyond those of younger children.
Aims: We conducted this study to investigate the treatment outcome of AYA ALL in Korea, and to define any patterns of care related to the treatment outcome of AYA ALL.
Methods: Clinical data of 10-29 years old ALL patients diagnosed between 2002 and 2010 were extracted from Korean national health insurance service. Data about patients' diagnosis, age, gender, mainly treated department (internal medicine *vs* pediatrics), usage data of medications (L-asparaginase, 6-mercaptopurine, vincristine, prednisolone or dexamethasone), hematopoietic stem cell transplantation (HSCT), radiotherapy, survival, and follow-up duration were collected. Patients who were treated with steroid over 2 weeks, and L-asparaginase at least once in initial 2 months were considered to be treated as pediatric protocol, and who did not fulfill this criteria were considered to be treated as adult protocol.
Results: Total 1,223 ALL AYA patients were diagnosed between the 2002 and 2010, and excluding those who never treated, 1,208 patients underwent ALL treatment. Among them, 665 (55%) patients were treated with pediatric protocol, and the other 543 (45%) patients were treated with adult protocol. Radiotherapy was done in 278 (41.8%) and 186 (34.3%) in each group, and HSCT was done in 205 patients (30.8%) and 216 patients (39.8%) in each group, respectively. Pediatric protocol group showed significantly better overall survival compared to adult protocol group in total age (65% *vs* 43%, $P<0.0001$), 10-13 year old (76% *vs* 57%, $P<0.0001$), and 20-24 year old patients (51% *vs* 31%, $P=0.0116$). In univariable analysis, patient age (younger), treatment protocol (pediatric), L-Asparaginase, 6-mercaptupurine, and steroid over 2weeks in initial 2 months were associated with better overall survival ($P<0.0001$ for each).
Summary/Conclusions: The overall survival rates in Korean AYA ALL were comparable with previous studies done at other countries. Patients treated with pediatric protocol tended to result better overall survival rate when compared to patients treated with adult protocol. Radiotherapy and early HSCT were widely used in the 2000s, and further study is needed to follow up the recent trend of treatment, and outcome as a result.

E853

AUTOLOGOUS TRANSPLANTATION AS TIME-DEPENDENT FACTOR FOR SURVIVAL OF PATIENTS WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: STUDY DATA AND SIMULATION MODEL

S. Kulikov[1,*], M. Rusinov[1], A. Kulikovsky[1], E. Parovichnikova[2]
[1]Biostatistics, [2]Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: The role of autologous hematopoietic stem cells transplantation (aHSCT) for patients with T-cell ALL is still being discussed. The resent Russia study of ALL shows the promising effect of aHSCT but there is a skepticism as the study was not randomized. The possible bias was referred to the "time selection" factor.
Aims: It's need to prove that time selection can not explain the magnitude of the effect of aHSCT on patient's survival.
Methods: We have developed SAS macros time-depend graphical and analytic procedures for time dependent factors: Land Mark (LM) methods, Mantel-Bayr test, Cox regression model (CM) and also a base for simulation all end points and study events like remission, transplantation, relapse and death are well approximated by a mixture of exponent distributions. Non-constant (dropping) hazard rate exists in real study data. The consequence of violation of constant hazard assumption as most possible source of biases was tested on our simulation model in different situations. Real data multicenter study of ALL was used to fit simulation model parameters. Russian ALL study group held a prospective multicenter trial RALL-2009 in the treatment of Ph-negative adult ALL patients based on non-intensive but non-interruptive treatment (NCT01193933). The therapy was unified for all Ph-negative ALL pts, but in T-cell ALL/LBL autologous hematopoietic stem cell transplantation (auto-HSCT) after non-myeloablative BEAM conditioning was scheduled as late intensification (+3-4 mo of CR) followed by prolonged 2 years maintenance. From Jan 2009 till Jul 2016, 30 centers enrolled 107 T-ALL/LBL pts. Median age was 28 years (15-54 y), 34 f / 73 m; early T-cell (TI/II) phenotype was verified in 56

(52.3%), mature (T-IV) - in 10 (9.4%), thymic (TIII, CD1a+) ALL – in 41 pts (38.3%). T-lymphoblastic lymphoma (T-LBL= <25% b/m blasts) was diagnosed in 22 pts (20,5%). Autologous HSCT was performed in 35, allogeneic-in 7 pts.
Results: The survival analysis of real data shows 4-fold dropping hazard rate. The effect of aHSCT was confirmed by LM analysis, Mantel-Bayr test - P_{MB}=.0004, Cox model output: 1/HR=15.9, P=0.008. (Fig.1). Simulation model for remission consists of 3 fractions: early (α=10%, τ=0.05 m, δ=0.2 m), normal (α=57%, τ=0.28 m, δ=1 m) and late remission (α=33%, τ=1.31 m, δ=2.2 m), for survival consists of 2 fractions: short life (α=59%, τ=22 m), long life (α=41%, τ=600 m). (Fig.2). The first simulation experiment was performed in preposition that transplantation has no effect (HR=1). To exclude the random effect the sample size was N=4000. Mantel-Bayr and Cox model show no significant (P_{MB}=.50, P_{CM}=.50, HR=.93) but LM plot demonstrates recognizable bias in transplanted patient group (Fig.3). The second experiment supposed that the existed effect of aHSCT (HR=0.5), N=500. Mantel-Bayr and Cox model would show significance, but hazard ratio was underestimated (PMB=.03, PCM=.03, HR=.70 (0.50-0.97)). More experiments were done for repeated simulation, which demonstrated a very good agreement of Mantel-Bayr and Cox methods and their robustness.

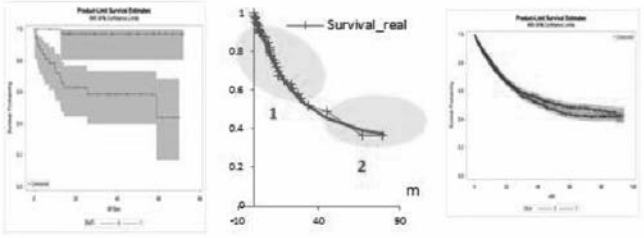

Figure 1. LM plot of RFS in transplanted (red line) and non-transplanted (blue line) groups of T-ALL patients.

Figure 2. Parametric interpolation model for the survival, 1-short life, 2-long life fractions.

Figure 3. LM plot for survival in simulation experiment. Overoptimistic 3% bias in 5-year survival for transplanted patients (red line).

Figure 1.

Summary/Conclusions: The effect of autologous HSCT in T-cell ALL was confirmed by usual analysis and by simulation experiments. It was shown that potential bias caused by no constant hazard rate cannot explain the magnitude of HSCT effect demonstrated on real data. LM plot could express small bias. Mantel-Bayr and Cox Model analytical methods are robust against violation of constant hazard assumption and give very concordant outputs. Cox model underestimates the effect of time-depending factor in case of dropping hazard. Simulations model is a good instrument for testing tests in situations of deviation from theoretical assumptions.

E854

INDUCTION WITH TYROSINE KINASE INHIBITORS, CONSOLIDATION WITH FLUDARABINE, ARA-C AND DAUNOXOME FOLLOWED BY ALLOGENEIC STEM CELL TRANSPLANT IS AN EFFECTIVE AND FEASIBLE STRATEGY FOR PH+ ALL PATIENTS

N. Di Felice[1,*], P. Minetto[1], F. Guolo[1], M. Clavio[1], N. Bisso[1], G. Pastori[1], D. Guardo[1], M. Gambella[1], A. Bellodi[2], E. Arboscello[2], N. Colombo[1], F. Ballerini[1], M. Miglino[1], R.M. Lemoli[1], M. Gobbi[1]
[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Clinic of Internal Medicine III, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOU San Martino-IST, Genova, Italy

Background: The prognosis of Philadelphia positive (Ph+) acute lymphoblastic leukemia (ALL) patients has improved since the introduction of tyrosine kinase inhibitors (TKI). Following TKIs treatment almost all patients rapidly achieve complete hematologic remission (CR). However, only a minority of patients obtain complete molecular response and mot of all will eventually relapse without further treatment. On the other hand, the concomitant combination of TKIs to conventional chemotherapy regimens greatly increases complete molecular responses, but at the price of significant toxicities and high rates of deaths due to toxicity.
Aims: We present here the preliminary results of a sequential therapeutic strategy starting with TKI (Dasatinib) as single agent induction until CR is achieved. Fludarabine (Flu), Cytarabine (Ara-C), Lyposomal Daunorubicine (DNX, FLAD regimen) and Dasatinib were given as consolidation therapy, in order to maximize efficacy and reduce toxicity. Allogeneic stem cell transplantation (HSCT) was planned for all patients in MRD negative CR.
Methods: Dasatinib was given in association with steroids at the dosage of 140mg /die until the achievement of CR. FLAD regimen consisted of a three-days administration of Flu 30mg/sqm followed by Ara-C 2000mg/sqm and DNX 100mg/sqm. Dasatinib was administered again from the end of chemotherapy and G-CSF was given to all patients starting from day 4 until complete hematological recovery. FLAD was administrated for up to two cycles. Minimal residual disease (MRD) was evaluated in all patients after each FLAD either by multicolor flow cytometry (MFC), RQ-PCR for VDJ rearrangements, and RQ-PCR for BCR/Abl.
Results: From January 2008 to December 2016, 8 Ph+ ALL at diagnosis (median age 52 years) have been enrolled in this protocol. The median follow-up was 27 months. All patients received 70 days induction with Dasatinib + Steroids and achieved CR with complete hematological recovery. In all patients but one, however, BCR/Abl was still positive both on day 33 and on day 70. Two patients were MFC MRD positive on day 33 (one on day 70 also), whereas five patients achieved MFC MRD negativity on day 33. After the first FLAD course all patients achieved MFC MRD negativity, with four patients achieving also negativity for VDJ rearrangements and BCR/Abl transcript. FLAD was very well tolerated, with a median ANC and platelet recovery of 7,5 and 4 days, respectively. No patient experienced relapse so far and 5/8 patients proceeded to HSCT. Two patients are currently waiting for transplant. Overall, 6 patients are alive and in MRD negative CR at the time of analysis. One patient died at day +289 after SCT due to non-relapse mortality and one has died after the first FLAD in molecular CR because of an unrelated event.
Summary/Conclusions: This therapeutic strategy proved to be well tolerated and extremely effective for Ph+ ALL patients. Administering FLAD in patients who had already achieved complete hematological response with Dasatinib + steroids allowed us to reduce the period of neutropenia and thrombocytopenia compared to what is reported after combined TKI and chemotherapy treatment given at diagnosis. Most patients underwent HSCT in molecular CR.

E855

BONE MARROW MRD EVALUATION ON DAY 7 OF STEROID TREATMENT OF MODIFIED ST JUDE TOTAL XV THERAPY IN STANDART/LOW RISK PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

S. Aytac[1,*], M. cetin[1], I. Yaman Bajin[1], I. Altan[1], S. unal[1], B. kuskonmaz[1], D. uckan[1], F. gumruk[1]
[1]Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: In the recent years it was cleary shown that levels of minimal residual disease (MRD) studied by flowcytometry during treatment reflect the overall response to the chemotherapy and give a chance to individualize treatment and improved outcome.
Aims: To determine the clinical significance of MRD on day 7 of initial steroid treatment in patients with childhood ALL we analyzed data from 173 patients treated with modified St Jude Total XV therapy between 1 January 2008 and 31 December 2015.
Methods: According to our previous succesfull results with high dose methl-prednisolone (HDMPX) we add 7 days of HDMPX to the modified St Jude Total XV as an initial treatment and randomized patients at doses of 10mg/kg/d or 20mg/kg/d HDMPX: not exceeding at maximum 1000mg methylprednisolone. After the end of 7th day of steroid concomittant chemotherapy was given and the doses were tapered gradually to 5mg/kg/d and 10mg/kg/d in each group respectively. By the 3rd week of treatment steroid dose was tapered to 2mg/kg/d in both groups and continued with this dose till the end of 3rd week of induction phase. MRD levels were studied at the 15th, 22nd and 42nd days of induction according to the protocol. However we also analyse steroid response rate by the peripheral smear on day 7. Moreover, patients were asked to obtain simultaneously optional bone marrow aspiration after getting informed consents to show whether there will be any concordance with the steroid response and/or whether it can give any idea of the outcome.
Results: Steroid response rate on day 7 by peripheral smear was 91% (n=158) for the whole group. However simultaneously bone marrow MRD measurement was done in 22 of the 173 patients.There were 13 female and 9 male patient with a median initial WBC count of 6400/mm3 (1100-55300/mm^3),all were Calla+ pre B cell ALL (17 low risk ALL, 6 standart risk and 1 high risk ALL),all were in complete remission and all except one is alive at the time of the analysis. There were 10 patients receiving 10mg/kg/d HDMPX and 12 patients were in the group of 20mg/kg/d HDMPX. MRD levels were not statistically different on day 7 between these two groups. Furthermore all patients except 2(one in each group) were steroid responsive by means of peripheral absolute blast count <1000/mm^3. Bone marrow MRD on day 15th and 42nd there were no statistically significant difference in each group(P>0.05).Although some of those patients in each group have high levels of MRD on day 7, interestingly they were all steroid responsive.
Summary/Conclusions: Our preliminary results suggest to think that MRD level on day 7 in a small group of low/standart ALL patients may not predict outcome.

E856

PONATINIB (PON) IN PHILADELPHIA CHROMOSOME (PH)-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): PRELIMINARY REPORT OF THE OPAL OBSERVATORY.

S. Tavitian[1,*], E. Raffoux[2], X. Thomas[3], P. Chevallier[4], M. Hunault[5], T. Leguay[6], K. Bilger[7], S. Lepretre[8], L. Legros[9], I. Cano[10], V. Lheritier[3], A. Virlojeux[1], H. Dombret[2], F. Huguet[1]

[1]Hematology, IUCT-O, TOULOUSE, [2]Hematology, Hôpital Saint-Louis, Paris, [3]Hematology, CHU, Lyon, [4]Hematology, CHU, Nantes, [5]Hematology, CHU, Angers, [6]Hematology, CHU, Bordeaux, [7]Hematology, CHU, Strasbourg, [8]Hematology, Centre Henri Becquerel, Rouen, [9]Hematology, CHU, Nice, [10]Hematology, CH, Versailles, France

Background: PON, a third-generation tyrosine-kinase inhibitor (TKI), displays activity in *de novo* Ph-positive (Ph+) ALL and chronic myeloid leukemia (CML) in lymphoid blastic phase (LyBP), as shown when given as single agent in 42 patients (pts) with resistant disease in the PACE trial (Cortes, NEJM 2013), or combined to first-line chemotherapy in 58 pts (Jabbour, Lancet Oncol 2015; Sasaki, ASH 2016).
Aims: Because data are still limited to few selected pts, we analyzed the outcome of pts treated with PON in the real-life setting (OPAL observatory).
Methods: Pts were recruited if aged ≥ 18 years; with *de novo* Ph+ ALL or CML-LyBP, treated by PON alone or in combination for at least 1 treatment day, for relapsed or refractory disease, between Apr 2012 and Dec 2014 (Expanded Access Program). Twenty-one pts were analyzed (16 men and 5 women; 17 *de novo* ALL and 4 LyBP-CML), with a median age of 60 years (22-73). Time from first ALL or CML-LyBP diagnosis was 6 months (1-123). At PON initiation, 1 pt had primary refractory ALL, 15 pts were in first salvage (1 in second complete remission [CR] after chemotherapy, 3 in molecular relapse only), 2 in second salvage, and 3 in third salvage or beyond. Numbers of patients who had previously received 1, 2, 3, or 4 other TKIs were 4, 15, 1 and 1, respectively (14 imatinib, 17 dasatinib, 5 nilotinib, 1 bosutinib). Six pts had previously undergone hematopoietic stem cell transplantation (HSCT). Of the 18 pts screened for *BCR-ABL* mutations, 5 had none, 3 had T315I, 3 had other PON-sensitive mutations, while 5 had compound mutations (known to be resistant to all TKIs including PON) and 2 had E255V (of intermediate sensitivity to PON). PON was administered alone in 13 pts, combined to low-intensity chemotherapy in 6 pts, intensive chemotherapy or monoclonal antibody in 2 pts. Dose at initiation was 45mg in 17 pts and 30mg in 4 pts.
Results: Median duration of PON therapy was 3 months (5 days-30 months+). Out of the 19 pts who received PON for ≥ 4 weeks, 5 pts failed to reach CR, while 14 (78%) reached or maintained it. Molecular response was not reported uniformly. During induction by PON, 5 grade 3-4 events occurred in 4 pts (1 pulmonary infection; 1 acute renal failure; 1 pancreatitis; 1 hepatitis; 1 venous thrombo-embolic event; no arterial occlusive event). Post-induction therapy consisted in PON-based therapy in most pts. HSCT was performed in 5 pts. Out of 14 pts in CR on PON, 1 pt died in CR from HSCT toxicity, 1 had a CNS relapse at 8 months, and 11 pts ultimately experienced bone marrow relapse, all of them within 6 months after PON initiation, except 2 who relapsed at 13 and 27 months after HSCT. Two patients are alive in CR at 14 and 30 months, 1 after salvage therapy, 1 on PON.
Summary/Conclusions: Our series of resistant pts is comparable to the PACE study population by initial characteristics and high frequency of *BCR-ABL* mutations. CR was achieved in most pts, suggesting the role of PON as a bridge-to-transplant with a favorable risk-benefit ratio. Effective post-induction combinations of PON to chemo/immunotherapy have to be tested in pts not eligible for HSCT. Because global outcome of this very high-risk population remains poor, earlier introduction of PON in the course of the disease is warranted, as underlined by the excellent results of the hyperC-VAD-PON combination in the first-line setting.

E857

JL1 ANTIGEN EXPRESSION OF LEUKEMIC CELLS IN CHILDHOOD ACUTE LEUKEMIA

E. You[1,*], S. Kim[2], C.-J. Park[1], S. Jang[1], Y.-U. Cho[1], C.H. Yoon[1], K.-N. Koh[3], H.J. Im[3], J.J. Seo[3]
[1]Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, [2]DiNonA, [3]Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: JL1 is a novel epitope of CD43, which is known to be specifically expressed depending on the differentiation stages of hematopoietic cells. JL1 antigen is expressed on tumor cells of T, B, and myeloid lineage in >80% of acute leukemia patients, and its expression is limited in normal multipotent hematopoietic cells. The antigen is not expressed on mature peripheral blood cells or other normal tissues. Thus, the clinical phase 1 test of a therapeutic agent for leukemia targeting JL1 is being conducted, and when anti-JL1 antibody was combined with a toxic substance, its therapeutic effect was found earlier in preclinical trials.
Aims: This study aims to examine JL1 expression of leukemic cells in childhood acute leukemia.
Methods: Between December 2014 and January 2016, a total of 71 patients younger than 21 years with acute myeloid leukemia (AML, n=25), and acute lymphoblastic leukemia (ALL, n=46) were enrolled in this study. Expression of JL1 was examined using FACSCanto II (Becton-Dickinson, Sunnyvale, CA, USA) based flow cytometry, and an expression of 20% or above was defined as positive JL1 expression. Pathologic and immunophenotypic characteristics, and clinical outcomes of the patients were analyzed.
Results: Positive JL1 expression was observed in 16 (64.0%) patients with AML, and 27 (58.7%) with ALL. In AML patients, positive JL1 group showed higher expressions than negative JL1 group in CD 14 (P=0.043), CD7 (P=0.026), CD56 (P=0.016) and lower expressions in CD65 (P=0.05). With regard to ALL patients, CD 20 (P=0.002) and CD2 (P=0.005) expressions were significantly higher in JL1 positive group than JL1 negative group. Positivity of JL1 expression did not show significant difference between B-lineage ALL and T-lineage ALL (P=0.671). Positivity of JL1 expression was not significantly associated with overall survival in 71 patients with newly diagnosed childhood acute leukemia (P=0.570).
Summary/Conclusions: 60.5% of childhood acute leukemia displayed positive JL1 expression. This finding is similar to 61.2% of JL1 expression in adult AML and 57.9% of expression in adult ALL reported previously. The JL1 expression was significantly associated with some immunophenotypic features, but was not significantly associated with clinical outcome. These findings demonstrates that anti-JL1 antibody might be used in childhood acute leukemia patient showing JL1 expression

E858

SERUM LEVELS OF CYTOKINES AND ADHESION MOLECULES AND THEIR ASSOCIATION WITH PROGNOSTIC FACTORS IN NEWLY DIAGNOSED ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

J.M. Horacek[1,2,*], T. Kupsa[1,2], J. Vanek[3], L. Jebavy[1,2], P. Zak[2]
[1]Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences (FMHS), [2]4th Department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, [3]Department of Informatics and Quantitative Methods, University of Hradec Kralove, Faculty of Informatics and Management, Hradec Kralove, Czech Republic

Background: Dysregulated production of cytokines and adhesion molecules has been implicated in the onset and progression of various types of leukemia. Further knowledge gained from multiple cytokine and adhesion molecule evaluation could help to improve treatment outcomes.
Aims: The aim of this study was to evaluate baseline levels of cytokines, cytokine receptors and adhesion molecules in newly diagnosed acute lymphoblastic leukemia (ALL) patients and to assess their correlation with baseline characteristics and prognostic factors.
Methods: A total of 30 newly diagnosed ALL patients (median age 46, range 22–75 years, 20 males) were included in this study. We evaluated serum levels of 31 analytes, specifically 21 cytokines, 4 soluble cytokine receptors, 5 soluble adhesion molecules and Matrix Metalloproteinase-9. From cytokines, we measured Interleukins (IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-15, IL-23), Epidermal Growth Factor (EGF), Granulocyte Macrophage Colony Stimulating Factor (GM-CSF), Interferon-γ (IFN-γ), Macrophage Inflammatory Protein-1α (MIP-1α), Monocyte Chemotactic Protein-1 (MCP-1), Tumour Necrosis Factor-α (TNF-α), Vascular Endothelial Growth Factor (VEGF) and soluble receptors for IL-2 (sIL-2Rα), IL-6 (sIL-6R), TNF-α type I and II (sTNFR-1,2). From soluble adhesion molecules, we measured E-Selectin (E-SEL), L-Selectin (L-SEL), P-Selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1) and Vascular Cell Adhesion Molecule-1 (VCAM-1). All analytes were measured by biochip array technology on Evidence Investigator analyzer (Randox). Serum levels of tested analytes were correlated with baseline characteristics and prognostic factors, such as age, sex, risk group according to GMALL (SR 9, HR 9, VHR 12 patients), full blood count parameters (including percentage of blasts), biochemical parameters (LDH, CRP), response to induction therapy (CR rate after induction), progression-free survival (PFS) and overall survival (OS). Statistical evaluation was done by a professional statistician using software R 3.3.2 (R Core Team 2016).
Results: Comparing analytes with baseline characteristics, we found significant negative correlations between IL-7 and leukocyte count (r=-0.633; p=0.032), percentage of blasts in peripheral blood (r=-0.695; p=0.004) and LDH (r=-0.604; p=0.075). Furthermore, we found significant positive correlations between IL-7 and platelet count (r=0.801; p<0.0001), VCAM-1 and LDH (r=0.664; p=0.012). Correlations with baseline risk stratification according to GMALL did not reach statistical significance. In the study population, CR rate after induction was 86% (MRD negative in 29%), 1-year PFS 68% and 1-year OS 73% (2 patients died during induction therapy). Higher levels of EGF were associated with failure to achieve CR after induction therapy (r=0.686; p=0.073). So far, no significant correlations between baseline analyte levels and inferior PFS or OS were found. In newly diagnosed ALL patients, we found statistically significant correlations between sTNFR-1 and sTNFR-2 (r=0.805; p<0.0001), IL-1α and IL-4 (r=0.700; p=0.008), sTNFR-2 and MIP-1α (r=0.657; p=0.037), sTNFR-2 and VCAM-1 (r=0.652; p=0.044). Other correlations between analytes did not reach statistical significance.
Summary/Conclusions: Our findings show that serum levels of IL-7 and VCAM-1 are associated with some baseline characteristics of newly diagnosed ALL patients and EGF with response to induction therapy. Better understanding of leukemia microenvironment is essential for development of new treatment approaches. Further studies in this field are warranted.

The work was supported by a long-term organization development plan 1011 (FMHS) and by MH CZ – DRO (UHHK, 00179906).

IMATINIB VS. DASATINIB FOR OUTCOMES AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH PH+ ACUTE LYMPHOBLASTIC LEUKEMIA

A. Shigematsu[1,*], S. Ota[1], H. Goto[2], K. Minauchi[1], J. Sugita[2], D. Hashimoto[2], M. Obara[1], T. Endo[2], M. Imamura[1], T. Teshima[2], N. Kobayashi[1]
[1]Department of Hematology, Sappro Hokuyu Hospital, [2]Department of Hematology, Hokkaido University Hospital, Sapporo, Japan

Background: The survival of the patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) who received allogeneic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment for Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.
Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.
Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuyu Hospital. The patients' eligibility were as follows: diagnosed as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.
Results: Sixty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the earlier years were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts), and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine-containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Other characteristics, such as age, disease status at HSCT, or stem cell source were not significantly different between the two groups. Incidences of Neutrophil engraftment and acute GVHD incidence were not statistically different between IMA-pts and DAS-pts. Incidence of chronic GVHD was marginally increased in IMA-pts (IMA; 63%, DAS; 33%, *P*=0.08). At the median follow-up days of 531 after SCT (range: 14-4402 day), overall survival was not different between the two groups by univariate analysis (Logrank, *P*=0.16). However, by multivariate analysis using Cox regression model for adjusting confounding factors, including, overall survival was superior for IMA-pts [Hazard ratio; 0.32 (0.11-0.94), *P*=0.04]. Incidences of transplant-related mortality and relapse were not different between the groups, even though relapse rate tended to be increased in DAS-pts (IMA; 16.1%, DAS; 47.1%, Gray *P*=0.2).
Summary/Conclusions: Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-SCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective fashion and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.

E860

IS OLDER AGE AN EXCLUSION CRITERION FOR ALLOGENEIC HEMOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA?

O. Gavrilina[1,*], E. Parovichnikova[1], V. Troitskaya[1], A. Sokolov[1], L. Kuzmina[2], S. Bondarenko[3], V. Lapin[4], T. Obukhova[5], A. Sudarikov[6], K. Zarubina[1], S. Kulikov[7], M. Rusinov[7], V. Savchenko[1]
[1]Chemotherapy and BMT, [2]Bone marrow transplantation, National Research center for hematology, Moscow, [3]BMT, Institute of the Pediatric Hematology and Transplantology, Saint-Petersburg, [4]Hematology, Regional hospital, Yaroslavl, [5]Cytogenetic, [6]Molecular hematology, [7]Statistic, National Research Center for Hematology, Moscow, Russian Federation

Background: Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL) is diagnosed more often in older than in younger patients. This type of the acute lymphoblastic leukemia is characterized by very aggressive course of the disease. All clinical recommendations for such conditions indicate allogenic bone marrow transplantation after achieving complete remission. The addition of tyrosine kinase inhibitors (TKI) to chemotherapy has dramatically improved the long-term outcome in Ph+ acute lymphoblastic leukemia patients. Nevertheless whether to administer chemotherapy at all and if yes – how intensive it should be, is still the matter of debate. We have conducted two consecutive trials in Ph+ ALL aiming to evaluate the efficacy of more and less intensive chemotherapy approaches in combination with constant non-stop 600 mg Imatinib. All patients in both protocols with suitable donors underwent hemopoietic stem-cell transplantation (HSCT).
Aims: To analyze the effectiveness of RALL–2009+TKI and RALL–2012+TKI protocols in Ph+ ALL patients with or without HSCT. To analyze the efficacy of treatment with or without transplantation regarding the patient's age.
Methods: From 2010 January to 2017 January, 35 new Ph+ ALL cases were diagnosed in 3 centers of the RALL–group. From 2010 to 2012, 12 Ph+ ALL pts were treated according to RALL–2009 protocol (ClinicalTrials.gov; NCT01193933) with concurrent administration of Imatinib. This protocol includes 8 cytostatic drugs and no intervals between treatment phases. Since 2012 till now 23 pts were included in ongoing RALL–2012 protocol, based mainly on 600 mg Imatinib with prednisolone, VNCR, L-asp, followed by 6-MP and MTX. Both protocols suggested the shift to Dasatinib (100-140mg) after non-achievement of MolCR on day 70 of treatment. MolCR was stated if *bcr/abl* chimeric transcript was <0,01% by PCR with 10^{-4} sensitivity. All patients were considered as candidates for allogeneic HSCT if HLA-identical donor was available. 13 pts (37%) underwent all0-HSCT as the first-line therapy: 1 autologous, 5 matched related and 7 matched unrelated.

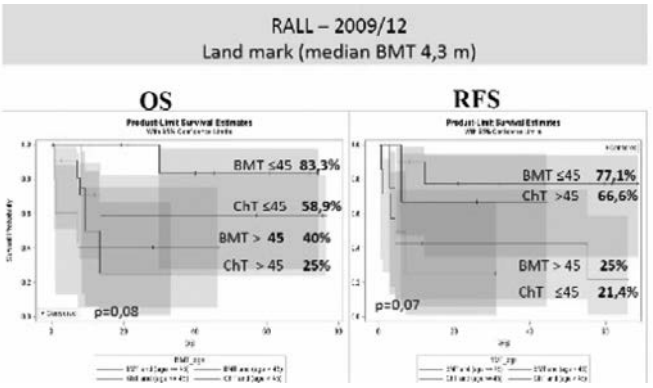

Figure 1.

Results: MolCR on day 70 was achieved in 36% and 59% in RALL–2009 (n=4) and RALL–2012 (n=13) respectively. Death on therapy (within 2 months of induction/consolidation) was registered in 2 cases on less intensive RALL-2012 protocol and 2 cases on RALL–2009. Hematological CR was achieved in 30 (85,7%) of 35 pts (except four early deaths and 2 refractory cases). There was one autologous HSCT in MolCR on the first protocol. Allo–HSCT was carried out in 5 of RALL–2009 protocol pts and in 9 of RALL–2012. The major issue is the non-relapsed mortality after unrelated allo–HSCT in 3 older pts (49, 56 and 59 years old) who were included in RALL–2012 (aGVHD and severe infections, at a median +4 months after HSCT and more than 12 months of CR duration).
The 5y overall survival (OS) and relapse-free survival (RFS) for all 35 pts constituted 54,6% and 40,4% respectively. The long-term outcome on both protocols (RALL–2009 and RALL–2012) was similar: OS – 62,8% *vs* 49,4% (p=0,6), RFS – 55,7% *vs* 45% (p=0,7), respectively. In order to evaluate the impact of allogeneic HSCT we performed a comparison of transplanted and non-transplanted patients by a landmark analysis. The land mark was chosen as the median time from CR to allo-HSCT – 4,3 mo (3-16 mo). So, the 5y OS from land mark was 53,3% for non-transplanted patients and from day of HSCT - 65,6% in transplanted (p=0,18), and RFS was 25% *vs* 62,5 (p=0,19), respectively. OS for older pts (>45 y) was 40% *vs* 25% in transplanted *vs* non-transplanted group of the pts, and RFS was 25% *vs* 66,6%, respectively. OS in younger (£45 y) pts was 83,3% *vs* 58,9% for transplanted *vs* non-transplanted pts, EFS was 77,1 *vs* 21,4%, respectively.
Summary/Conclusions: The results very pessimistic in older (>45 years) patients who received HSCT. The contrary was observed in younger adult patients with very good results after HSCT – OS was 83,3% and EFS 77,1%. We conclude that patients aged>45y should continue chemotherapy without allogeneic HSCT or may be we could apply autologous HSCT for that group of the patients.

TARGETABLE BLINATUMOMAB + TYROSINE KINASE INHIBITORS TREATMENT IN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS: CLINICAL EFFECTIVENESS AND PERIPHERAL LYMPHOCYTES SUBPOPULATIONS KINETICS

A. Sokolov[1,*], E. Parovichnikova[1], V. Troitskaya[1], I. Galtseva[1], L. Kuzmina[1], J. Davidova[1], N. Kapranov[1], I. Lukyanova[1], T. Lobanova[1], K. Zarubina[1], E. Usikova[1], V. Savchenko[2]
[1]National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation, [2]Chemotherapy of hemoblastoses and bone marrow depression and bone marrow transplantation, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Blinatumomab is a bispecific monoclonal anti-CD3/CD19 antibody which has clinical activity in relapsed/refractory Ph-positive acute lymphoblastic leukemia (ALL) as monotherapy. Combination of Blinatumomab with

tyrosine kinase inhibitors (TKI) is the promising approach in treating Ph-positive ALL. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.
Aims: To demonstrate effectiveness and toxicity profile of Blinatumomab+TKI treatment. To evaluate peripheral blood lymphocytes subpopulations kinetics during blinatumomab treatment.

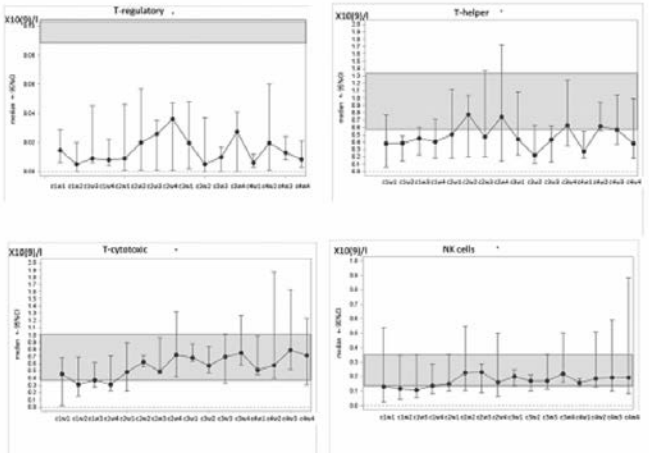

Figure 1.

Methods: From October 2015 to February 2017 10 patients (pts) aged from 24 to 42 (median 31), 7 female and 3 male, with relapsed/refractory ALL were treated in our center. The diagnosis was relapsed ALL in 8 pts (7 – overt hematological, 1 – cytogenetic relapse) and persistent/increasing minimal residual disease of ALL in 2 pts. All pts had strong CD19 positivity. 8 pts was diagnosed as Ph-positive ALL (p190), 1 – Ph-like ALL (IKZF1 rearranged), 1- FLT3+ ALL. Two pts has T315I ABL mutation. In all pts blinatumomab continuous infusion + TKI therapy was started. Blinatumomab dose during 1st week of 1st cycle was 9 mcg/day, 28 mcg – subsequent three weeks. Blinatumomab dose in subsequent 4-weeks cycles was 28 mcg/day. 7 pts were treated with TKI Dasatinib, 1 – Bosutinib (Dasatinib/Nilotinib intolerant), 1 – Ponatinib (T315I), 1 – Sorafenib (FLT3+). ATRA was added to Dasatinib in 1 pt with IKZF1rearranged Ph-like ALL. 1 pt received 1 cycle of 4 weeks blinatumomab, 1 pt – 2 cycles, 6 pts - 4 cycles, 2 pts – 5 cycles. TKIs were administered continuously in all pts. T-helper, T cytotoxic, T-regulatory and NK cells were measured by flow cytometry in every week during all cycles of blinatumomab treatment.
Results: No one pt has neurological toxicity of any grade. All pts has significant decrease of normal IgG level and all of them received intravenous human normal immunoglobulin replacement. Palmar-plantar syndrome in one pt on sorafenib completely resolved after temporarily TKI discontinuation. Diarrhea in 1 pt on dasatinib/nilotinib completely resolved on bosutinib. 8 pts achieved molecular remission (MolCR), one pt – cytogenetic remission and one pt with T315I progressed to overt hematological relapse. T-helper and T-regulatory lymphocytes subpopulations were on or below of lower limit of normal range. T-cytotoxic and NK subpopulations gradually returned into normal range (Fig. 1). AlloBMT was performed in 4 pts. Three pts are awaiting alloBMT and three are continuing Blinatumomab + TKI treatment.
Summary/Conclusions: Lowering toxicity in non-chemotherapy treatment has its significance in such a heavily pretreated patients with relapsed ALL. The treatment has high MolCR rate and low toxicity profile. Treatment effectiveness correlated with T-helper and T-regulatory subpopulations exhausting. T-cytotoxic and NK cells subpopulations restoring also correlated with clinical effectiveness.

E862

VERY VERY LATE RELAPSES OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA, A CASE SERIES

M. Baka[1], D. Doganis[1], M. Nikita[1,*], A. Pourtsidis[1], M. Servitzoglou[1], D. Bouhoutsou[1], M. Varvoutsi[1], K. Kapetaniou[1], H. Dana[1], V. Douna[2], T. Anastasiou[2], H. Kosmidis[1]
[1]Pediatric Oncology Department, [2]Hematology Lab, P.&A. Kyriakou, ATHENS, Greece

Background: Recurrence of acute lymphoblastic leukemia (ALL) during childhood usually occurs within the first six years after initial diagnosis.
Aims: The aim of this study is the identification of all relevant characteristics and outcomes in a group of patients with childhood ALL, who relapsed more than six years after initial diagnosis or more than three years after bone marrow transplantation (BMT).
Methods: All children diagnosed with a first relapse of ALL in our Department, from January 1992 till December 2010 were included in this study.
Results: During this period, a total number of 353 patients with childhood ALL were treated in our Department, according to BFM protocols. Recurrence occurred in 86 patients (24.4%, 56 male - 30 female - median age: 4,83 years), within 3 to 184 months from initial diagnosis. Very very late recurrence was noted in 3,1% of our relapses (8 male - 3 female) at 53, 72, 82, 83, 84, 87, 108, 112, 116, 120 and 184 months from initial diagnosis. In 9 patients recurrence involved the bone marrow, in 1 both bone marrow and central nervous system (CNS) and in 1 only the testicles. Two children had received allogeneic BMT from a matched related donor in first complete remission (CR1) and they had a bone marrow relapse 4 and 5 years later, respectively. The mean WBC, Hb, Blasts and PLT values at diagnosis were 29260/mm3, 5.6g/dl, 21360/mm3 and 18000/mm3, respectively. All of them were B-cell ALL except for 1 who had CD33 and CD13 co-expression. Regarding the immunophenotypical profile of the disease at recurrence, it remained almost identical to the initial. Regarding cytogenetic characteristics of the patients at diagnosis, 3 of them had high hyperdiploidy, one del(6)(q12), one BCR-ABL fusion and one 47,XY,+13(9),idem,del(12(p13?); none had MLL rearrangement or ETV6-RUNX1. In 9 cases, the cytogenetic profile remained identical at recurrence, while in 1, trisomia 13 was not detected and another had heterozygous absence of IKZF1, PAX5, EBF1, CDKN2A and CDKN2B genes. On Day 8, nine of 11 patients were Prednisone Good Responders. On Day 15, nine children had bone marrow M1, one M2 and one M3, and on Day 33 only one had M2. Two patients were classified as low risk, 6 as intermediate risk and 3 as high risk. Second remission (CR2) was achieved in 9 children with very very late recurrence. The other 2 died from disease progression. Six of nine patients are still alive and well 6, 8, 10, 10, 11 and 20 years after initial diagnosis. One of 9 patients died from second recurrence and the last two had a second allogeneic BMT and died due to severe infection, 2 and 10 months following that BMT. Interestingly, 3 out of 5 patients who finally died, had the very very late recurrence (10, 10 and 15 years after initial diagnosis) and had been treated with adult type protocols.
Summary/Conclusions: The rate of very very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.

E863

NOVEL CRLF2 MUTATIONS AND CLINICAL SIGNIFICANCE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

Z. Ge[1,2], Y. Gu[2,3], Q. Han[2,3], X.-L. Zhou[2,3], B.-A. Chen[1,2], J.-Y. Li[3], C. Song[2,4,*]
[1]Hematology Department, [2]International Cooperative Leukemia Group and International Cooperative Laboratory of Hematology, Zhongda Hospital, Southeast University Medical School, [3]Hematology Department, The First Affiliated Hospital of Nanjing Medical University Jiangsu Province Hospital, Nanjing, China, [4]Pediatrics Department, Penn State University College of Medicine, Hershey, United States

Background: Cytokine receptor-like factor 2 (*CRLF2*) plays an important role in the development of normal B lymphocytes, which can mediate early B cell proliferation and survival. *CRLF2* overexpression and rearrangement have been observed in acute lymphoblastic leukemia (ALL); and they are reported to contribute to oncogenesis and unfavorable outcome in ALL. We reported that *CRLF2* overexpression in the patients without *CRLF2* rearrangement, indicating the reason other than *CRLF2* rearrangement is responsible to the *CRLF2* overexpression. There is few reported *CRLF2* mutations in adult ALL.
Aims: This study is to investigate the mutations of *CRLF2* and its clinical significance in adult ALL without *CRLF2* rearrangement.
Methods: The 129 patients' BM samples (95 B-ALL, 33 T-ALL and 1T-/B-ALL) were collected between April 2010 and Jan 2015 at the First Affiliated Hospital of Nanjing Medical University. The ALL diagnosis was made according to the cytogenetic, morphologic, Immunophenotypic and molecular criteria of WHO Diagnosis and Classification of ALL (2008). Mutational analysis of *CRLF2* exons 1-6 was performed. Genomic DNA was isolated and DNA fragments spanning the aforementioned *CRLF2* exons were amplified by PCR using AmpliTaq Gold kit (Applied Biosystems, USA) and the exon-specific primers. The resulting PCR products were purified and sequenced by The Beijing Genomics Institute (BGI; Beijing, China).The frequency, positions, types and clinical significance of *CRLF2* mutations were analyzed. For qualitative parameters, overall group differences were analyzed using a $\chi 2$ test. All statistical analyses were performed using SPSS version 17.0 (SPSS, Inc., Chicago, IL, USA). $P<0.05$ was considered to indicate statistical significance.
Results: Six novel *CRLF2* mutants were detected in the 129 patients without *CRLF2* rearrangement, which were L86I (0.8%), R186S (7.8%), P224L (8.5%), W255C (0.8%), and two silent mutations F232F (0.8%) and A11A (12.4%). The overall rate of *CRLF2* mutation was 26.6%. Exon6 is a hot spot exon, detected three types of mutants. The incidence of A11A in B-ALL was significantly higher than that in T-ALL (14.7% *vs* 2.4%, *P*=0.037), whereas R186S was only detected in B-ALL. Exon1, exon5 and exon6 mutations were detected in B- and/or T-ALL patients; but no mutations were detected in exon2 and exon4. None of these mutations were reported in the COSMIC and SNP databases. The patents with R186S, P224L mutations showed significant differences with that of non-mutant patients in sex, age, white blood cell count, hemoglobin level, and platelet count. The median neutrophil count in the patients with P224L mutation

was lower than that of non-mutation (8.53x10^9/L *vs* 28.9x10^9/L, *P*=0.032). The positive rate of Ph chromosome in patients with R186S was lower than that without the mutant (10.0% *vs* 31.8%, *P*=0.018). In addition, the incidence of splenomegaly in patients with R186S and P224 L mutants was lower than that in non-mutant patients (0.0% *vs* 29.5%, *P*=0.026; 0.0% *vs* 29.7%, *P*=0.034, respectively). The B-ALL patients with L86I mutant had myeloid antigen expression, high white blood cell count (248.4×10^9/L) and low platelet count (10×10^9/L), and relapsed in two months after the first induction chemotherapy; and the overall survival was only 2 months. The patient with W255C mutation did not achieve complete remission (CR) with the first induction chemotherapy. Interestingly, the patient with silent mutation, A11A showed higher age (46 *vs* 30 years, *P*=0.033), higher HLA-DR (100% *vs* 75.3% *P*=0.035), CD22 (83.3% *vs* 47.4% *P*=0.020) than those without the mutation; and the patient with F232F mutation relapsed in 6 months.

Summary/Conclusions: Six novel *CRLF2* genetic mutations were identified in adult ALL patients and may associate with clinical outcome, such as *CRLF2* R186S indicating favorable, while L86I and W255C indicating poor outcome. Our data indicated that the *CRLF2* mutations may be new prognostic markers and play an important role on oncogenesis in ALL.

THE MUTATIONAL SPECTRUM OF T(8;21)(Q22;Q22) POSITIVE ACUTE MYELOID LEUKEMIA DETERMINED BY HIGH-THROUGHPUT TARGETED SEQUENCING

N. Jahn[1,*], A. Dolnik[1], M. Agrawal[1], S. Cocciardi[1], L. Schmalbrock[1], T.J. Blätte[1], V.I. Gaidzik[1], P. Paschka[1], D. Weber[1], A. Kündgen[2], M. Wattad[3], G. Held[4], H.A. Horst[5], F. Thol[6], M. Heuser[6], A. Ganser[6], R.F. Schlenk[1,7], H. Döhner[1], L. Bullinger[1], K. Döhner[1]

[1]Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, [2]Klinik für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Düsseldorf, Düsseldorf, [3]Klinik für Hämatologie, internistische Onkologie und Stammzelltransplantation, Evangelisches Krankenhaus Essen-Werden, Essen, [4]Innere Medizin I, Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, [5]Klinik für Innere Medizin II, Universitätsklinikum Schleswig-Holstein Campus Kiel, Kiel, [6]Klinik für Hämatologie, Hämostaseologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, [7]Nationales Centrum für Tumorerkrankungen (NCT), Universität Heidelberg, Heidelberg, Germany

Background: Recently, comprehensive genetic profiling of pediatric and adult core-binding factor (CBF) AML revealed a variety of cooperating events in a cohort of 85 t(8;21) AML patients (Faber *et al. Nat Genet* 2016). These mutations comprised alterations in genes encoding for proteins in tyrosine kinase (TK) signaling, epigenetic regulation (ER), and in the cohesin complex (CC).
Aims: To validate and to further extend our recent findings by comprehensive characterization of the mutational landscape of t(8;21) positive AML using a high-throughput targeted sequencing (HTS) approach.
Methods: The HTS panel comprised the entire coding region of 244 genes that are involved in hematological malignancies. Pretreatment blood (n=23) or bone marrow specimens (n=72) of 95 additional adult t(8;21) positive AML patients (pts) (median age: 51 yrs, range 18-72 yrs) were analyzed. 92/95 pts were enrolled in one of seven prospective AMLSG treatment trials. Libraries (total probes size: 1.359 Mbp) were prepared using SureSelectXT custom solutions (Agilent). Paired-end sequencing was carried out on a HiSeq 2000 (Illumina). The variant allele frequency (VAF) cutoff for reporting mutations was set at ≥0.05.
Results: The median coverage per pt was 900x. Mutations were detected with an average of 5.1 (SD: ±2.6) per pt with 99% of all pts harboring at least 1 mutation and 87% ≥ 3 mutations. Consistent with previous studies, mutations in TK signaling pathways were common events: *KIT* mutations were found in 22/95 pts (23%) followed by mutations affecting *NRAS* (16/95; 17%), *FLT3* (11/95; 12%; point mutations only), and *KRAS* (4/95; 4%). A significant enrichment of mutations was also observed in genes involved in epigenetic regulation, *ASXL1* (15/95; 16%), *ASXL2* (12/95; 13%), *KDM6A* (11/95; 12%), *CREBBP* (8/95; 8%), *SRCAP* (8/95; 8%), *EZH2* (7/95; 7%), *SETD2* (5/95; 5%), *TET2* (12/95; 13%) and *DNMT3A* (5/95; 5%), highlighting their contribution in altering the epigenetic state of this leukemia subtype. Moreover, mutations affecting members of the CC were found with a high frequency: *RAD21* (13/95; 14%), *SMC1A* (5/95; 5%), *STAG2* (3/95; 3%), and *SMC3* (2/95; 2%). Of note, mutations in CC genes were almost mutually exclusive. We also identified additional mutations in previously detected cooperating genes such as mutations clustering in exon 2 of the *ZBTB7A* gene (15/95; 16%), encoding for a transcription factor involved in hematopoietic lineage fate. Recurrent mutations were also observed in *CCND2* (9/95; 9%), that plays an important role in regulation of hematopoietic cell proliferation, as well as *DHX15* (6/95; 6%) being involved in spliceosome function and ribosome biogenesis. With respect to the clonal architecture we found that the median VAF in genes belonging to ER and CC (0.30; range 0.03-0.91; 0.31, range 0.05-0.73; respectively) was higher than in genes associated with TK signaling (0.19, range 0.05-0.53). These data suggest that alterations affecting the epigenetic state and differentiation occur earlier than those in signaling during t(8;21) leukemogenesis.
Summary/Conclusions: Using a comprehensive, deep sequencing approach we could further characterize the mutational landscape of t(8;21) positive AML. Here, mutation clusters in genes involved in TK signaling, ER and CC were confirmed as well as novel CBF-associated gene mutations that play an essential role in regulation of hematopoietic cell proliferation and differentiation. Further analyses in terms of sample size extension as well as correlation of findings with clinical parameters are ongoing.

E865

NFKB PATHWAY PROMOTES TUMOR PROGRESSION THROUGH BRUTON'S TYROSINE KINASE IN MLL+ ACUTE MYELOID LEUKEMIA

S.C. Nimmagadda[1,*], S. Frey[1], B. Edelmann[1], T. Fischer[1]

[1]Department for Hematology and Oncology, University Clinic of Magdeburg, Magdeburg, German

Background: Mixed Lineage Leukemia's (MLL's) are characterised cytogenetically by reciprocal translocations of the MLL gene and clinically by unfavourable outcomes. Evidence indicating that MLL leukemia's are resistant to apoptosis encourages the identification of novel drug targets.
Aims: Using cord blood (CB) CD34+ cells (control) and CB CD34+ cells expressing MLL-AF9, we sought to determine the potential role of BTK in the development and progression of MLL+ leukemia. We further aimed to uncover possible downstream target/s of BTK, improving the therapeutic efficacy of the drugs used.
Methods: Experiments were performed using control and MA9.3 cells and leukemic blasts from 3 AML (MLL+) patients. Signalling events were evaluated by immunoblotting. p65 mediated BTK expression was determined by promoter assays. Cells were treated with specific inhibitors of BTK (Ibrutinib (IBR): 0.25, 0.5, 1.0 and 2μM) in combination with Daunorubicin (DAU 5nM) or RAC (NSC 23766 (NSC): 5, 10, 15 and 20μM) for 48 hrs and cell viability was assessed using Annexin V/ Sytox-Blue based flow cytometric analysis.
Results: To determine the relevance of BTK as a therapeutic target in MLL+AML, we examined the whole cell lysates (WCL) from control cells, two clones of CB expressing MA9 (MA9.3 and .6) and leukemic blasts from the 3 AML patients. Activated BTK (pY223) was detectable in both the clones of MA9 and MLL+AML samples. Interestingly, the cells demonstrated activation of p65 (pS536) but not in control cells. To address if activated p65 could potentially drive BTK expression, we performed BTK promoter assays with reporter construct and empty vector. MA9.3 cells electroporated with test construct demonstrated significantly higher transcriptional activity. At the protein level, p65 inhibitor treatment (MG132 or Bay 11-7082) reduced total BTK expression, indicating the involvement of activated p65 in the expression of BTK. Treatment of control and MA9.3 cells with various concentrations of IBR for 48 hrs induced a dose-dependent reduction of cell viability (Annexin V and Sytox blue negative). We further sought to determine if the use of IBR in combination with Daunorubicin would further sensitize MA9.3 cells. The apoptotic rate of the cells with combination treatment was significantly higher than that of cells treated with IBR or DAU alone. The coefficient of drug interaction (CDI) values indicated that IBR-DAU combination synergistically reduced cell viability (CDI >1.0-antagonistic; <1.0 synergistic and =1 additive effect). Recent studies suggested RAC-GTPase signaling may also represent a target in AML, particularly in the context of *MLL* gene rearrangements (Wei J et al., Cancer Cell 2008 and B Mizukawa et al., Blood 2011). This intrigued us to test if BTK is possibly upstream of RAC. We measured activation of the GTPase RAC via active RAC pull down assay. Interestingly, treatment with IBRU significantly reduced RAC activation, positioning BTK upstream of RAC. In line with observations reported earlier; we also observed that MA9.3 cells are responsive to RAC inhibitor, NSC. This effect of NSC on cell viability was further potentiated in combination with IBR (0.5μM). CDI values once again indicated that the drugs together have a synergistic effect on reducing the cell viability.
Summary/Conclusions: Taken together, our data support a biological link between NFκB, BTK and RAC pathways in the modulation of cell survival in MLL-rearranged AML cells. Aberrantly active p65 drives the expression of BTK and contributes to the progression of the AML. Combination treatment using IBR-DAU and IBR-NSC might be a promising therapeutic strategy, minimizing high drug dose-related side effects but increasing the therapeutic efficacy.

A PRECISION MEDICINE PLATFORM FOR ACUTE MYELOID LEUKEMIA TO HELP UNRAVELING THE MOLECULAR ADDICTIONS OF FLT3-ITD-DRIVEN AML

P. Ayuda-Durán[1,*], B. Zhang[1], L. Piechaczyk[1], M. Popa[2], D. Tadele[1], A. Rowe[3], J. Robertson[1], T. Gedde-Dahl [4], E. Mc Cormack[2], B.T. Gjertsen[2], Y. Fløisand[4], J.M. Enserink[1]
[1]Department of Molecular Cell biology - Institute for Cancer Research, Oslo University Hospital - Radiumhospitalet, Oslo, [2]Department of Hematology, University of Bergen, Bergen, [3]Department of Microbiology, [4]Department of Hematology, Oslo University Hospital - Rikshospitalet, Oslo, Norway

Background: Acute myeloid leukemia (AML) is an aggressive disease with poor prognosis (Tzelepis *et al.* 2016). No single driver mutation is present in all cases of AML, making its treatment a challenge (The Cancer Genome Atlas Research 2013). Current standard of care for AML is an aggressive cytostatics-based treatment that has remained unchanged for the past 30 years (Longo *et al.* 2015). Weak or elderly patients might not be eligible for intensive treatment, leading to poor survival rates. Many such patients are labeled as "untreatable", although a portion of them could benefit from specific, individualized treatment. A precision medicine strategy can help to find the specific treatment for these 'untreatable' AML patients.
Aims: Drug-driven personalized medicine aims to directly test the sensitivity of primary cancer cells taken from individual AML patients to a selection of targeted cancer drugs, compare these results with drug sensitivities of healthy donor samples and select the most effective drug for each patient. This approach considers any combination of mutations or epigenetic changes that might not be found in the standard sequencing panels, an advantage when dealing with such a heterogeneous disease. Proof of principle of this strategy was recently demonstrated by FIMM (Helsinki, Finland) (Pemovska *et al.* 2013), not only providing immediate clinical benefit to leukemia patients, but also identifying drugs that can potentially be repurposed for future treatment of patients.
Methods: We have established a drug-driven personalized medicine platform for AML where we check the *ex-vivo* drug sensitivity and resistance of bone marrow primary cells to a panel of around 400 drugs and drug combinations covering the standard of care treatments, cancer chemotherapeutics as well as many clinically available and emerging molecularly targeted compounds. We calculate the IC_{50} values for all the drugs for each individual donor or patient, and then the differential drug sensitivity scores, selecting the drugs that affect preferentially the cancer cells when compared with healthy cells. To date we have successfully processed 6 healthy donors and 66 AML samples identifying subgroups of patients who respond with a similar dynamic to certain classes of drugs, as the subgroup of cells carrying internal tandem duplications in the receptor tyrosine kinase FLT3 (FLT3-ITD).
Results: FLT3 activating mutations, particularly FLT3-ITD, have been observed in approximately 30% of AMLs (The Cancer Genome Atlas Research 2013), and are associated with increased risk of relapse and poor clinical outcome (Abu-Duhier *et al.* 2008). The cellular pathways that support FLT3-ITD-driven cell proliferation and survival remain poorly understood. We discovered that FLT3-ITD-expressing AML blasts show an enhanced sensitivity to HSP90 inhibitors such as Ganetespib compared to healthy donors and any other subgroups of leukemia. In addition, HSP90 inhibitors specifically sensitize FLT3-ITD-expressing bone marrow-derived cells to TKIs, whereas cells derived from healthy donors are unaffected. HSP90 inhibitors also preferentially eradicate a population of patient-derived FLT3-ITD+ AML cells expressing leukemic stem cell markers.
Summary/Conclusions: In summary, our study reveals a molecular basis for HSP90 addiction of FLT3-ITD-driven AML and provides a rationale for treatment of this form of AML with HSP90 inhibitors.

E867

SECRETION OF SOLUBLE FACTORS BY AML CELLS INFLUENCE CD33/CD3 BITE® ANTIBODY MEDIATED CYTOTOXICITY AND T-CELL PROLIFERATION

M. Costanzi[1,2,*], C. Krupka[1,2], R. Kischel[3], P. Kufer[3], T. Köhnke[1,2], K. Spiekermann[2,4], W. Hiddemann[2,4], M. Subklewe[1,2,4]
[1]Laboratory for Translational Cancer Immunology - Gene Center, [2]Department of Internal Medicine III, Hospital of the Ludwig-Maximilians-University (LMU) Munich, [3]AMGEN Research GmbH, Munich, [4]German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In our previous work, we showed that the CD33/CD3 BiTE® antibody construct (AMG 330) is able to recruit autologous, residual T cells and induce cytotoxicity against primary AML cells *ex vivo*. However, as described previously (Mussai et al, Blood 2013) primary AML cells are able to secrete soluble factors, which might not only influence T-cell proliferation but also negatively impact AMG 330 mediated cytotoxicity.
Aims: In this study we characterized the influence of soluble factors secreted by primary AML cells on AMG 330 mediated cytotoxicity.
Methods: We used plasma samples (from heparinized serum tubes or after density gradient centrifugation) from newly diagnosed and relapsed AML patients in AMG 330 cocultures of healthy donor (HD) T cells and AML cell lines. In flow cytometry based experiments we determined the influence of AML plasma in comparison to fetal calf serum (FCS, heat inactivated) on AMG 330 mediated cytotoxicity and T-cell proliferation. In transwell experiments using primary AML cells physically separated from AMG 330 cocultures, we evaluated if AML cells are the source of soluble factor secretion.
Results: The influence of AML plasma from bone marrow (BM) of AML patients on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: In 15/30 samples, AMG 330 mediated cytotoxicity was significantly reduced compared to cultures containing FCS (mean% specific lysis FCS *vs* BM: 72.8 *vs* 25.1). This was accompanied by a reduction in T-cell proliferation (mean% proliferation FCS *vs* BM: 27.7% *vs* 9.5%). The degree of immunosuppression could not be correlated to percentage of bone marrow blasts. Interestingly, the effect was not observed in AML plasma samples from peripheral blood (PB) (mean% specific lysis FCS *vs* PB: 84.7 *vs* 83.5;% proliferation FCS *vs* PB 32.2 *vs* 36.5, n=19). In the remaining 15 plasma samples from AML BM no influence on AMG 330 mediated T-cell function was observed (mean% specific lysis FCS *vs* BM: 82.1 *vs* 78.3;% proliferation FCS *vs* BM: 25.7 *vs* 26.8). In control cultures plasma from AML patients in complete remission (CR) or from HD BM was used which did not negatively impact AMG 330 mediated cytotoxicity (mean% specific lysis FCS *vs* CR: 95.6 *vs* 94.4, n=5; FCS *vs* HD: 89.6 *vs* 90.5, n=6), or T-cell proliferation (FCS *vs* CR: 76.6 *vs* 68.2; FCS vs HD: 58.9 *vs* 65.4). To further explore the influence of soluble factors from primary AML cells, we performed transwell experiments. Primary AML cells were cultured in the previously described long term culture system (Krupka et.al, Leukemia 2016) and HD T cells and MOLM 13 cells were placed in transwell devices (3μm). In analogy to our findings with AML BM plasma, we observed a strong reduction in AMG 330 mediated cytotoxicity and T-cell proliferation in 7/14 experiments (mean% specific lysis control *vs* AML: 95.0 *vs* 70.8;% proliferation control *vs* AML 78.6 *vs*

41.8, n=7). In the remaining 7 primary AML samples, no immunosuppressive effect was observed (mean% specific lysis control *vs* AML 98.9 *vs* 98.2;% proliferation control *vs* AML 82.8 *vs* 77.7, n=7).
Summary/Conclusions: In summary we demonstrated that BM derived plasma from AML patients at primary diagnosis or relapse reduced T-cell proliferation and AMG 330 mediated cytotoxicity in half of the samples tested. The immunosuppressive factors were secreted by primary AML cells as demonstrated by transwell experiments. Unraveling mechanisms of resistance to BiTE^{O} antibody mediated cytotoxicity will allow the exploitation and usage of enhanced strategies to increase response rates.

Background: Internal tandem duplications (ITD) in the receptor tyrosine kinase *FLT3* occur in about 22% of patients (pts) with acute myeloid leukemia (AML) and confer a poor prognosis depending on the mutational load. The multi-targeted tyrosine kinase inhibitor (TKI) midostaurin has been shown to improve outcome in *FLT3*-ITD positive (*FLT3*-ITD^{pos}) and *FLT3*-TKD mutated (*FLT3*-TKD^{mut}) pts in combination with intensive chemotherapy [CALGB 10603 (RATIFY) trial], thus representing a promising targeted treatment approach. However, a significant number of pts relapse after initial response due to yet unknown mechanisms.
Aims: To study the clonal evolution in *FLT3*-ITD^{pos} pts treated in the AMLSG16-10 (NCT01477606) or CALGB 10603 (RATIFY, NCT00651261) trial in paired samples obtained at diagnosis (Dx), complete remission (CR) and relapse (Rel) by whole exome sequencing (WES).
Methods: WES was performed in 17 *FLT3*-ITD^{pos}pts using the Nextera Rapid Capture Exome kit (Illumina) for library preparation followed by sequencing on a Illumina HiSeq2000. 6 pts were treated in the RATIFY trial receiving either midostaurin or placebo combined with intensive chemotherapy during induction and consolidation; 11 pts were treated in the AMLSG16-10 trial, which includes treatment with midostaurin combined with intensive chemotherapy during induction and consolidation followed by a one-year maintenance therapy with midostaurin; 4 pts in the AMLSG16-10 trial received allogeneic hematopoietic cell transplantation. The presence of *FLT3* and *NPM1* mutations (mut) and the allelic ratio (AR) of *FLT3*-ITD were analyzed according to standard protocols.
Results: The median AR of *FLT3*-ITD was 0.51 (0.10-18.94) and 0.54 (0.07-26.31) at Dx and Rel, respectively. Loss of *FLT3*-ITD was observed in 5 pts; changes of the ITD clone at Rel occurred in 7 pts. Of those, 5 pts had a change of the insertion site and 1 pt gained an additional ITD clone at Rel. 3 pts had a D835Y *FLT3*-TKD^{mut} that was lost at Rel. 6 pts had a *NPM1*^{mut} that persisted at Rel in all pts. Using WES, 301 mut (226 missense, 24 nonsense, 41 indels, 6 splice sites, 4 unknown) were identified. The average coverage was 125 (186-67) among all samples. 131 (43%) mut were present at both time points (Dx and Rel). 83 (28%) mut were found only at Dx or only subclonal at Rel. 73 (24%) mut were detected only at Rel and 14 mut with only 1 read at Dx. Besides *FLT3*-ITD, the average number of mut per sample (Dx or Rel) was 13. Mut were most frequently observed in genes related to signaling (23%), transcription (20%), DNA methylation (5%), chromatin-cohesin (4%), components of the membrane (4%) and ubiquitin-proteasome (4%). Pre-leukemic mut (*DNMT3A*, *TET2*, *IDH1/2*) were detectable in 10 pts at both time points and persisted at CR in 7 pts. Recurrent mut in transcription related genes occurred in 8 pts at Dx and Rel, with *WT1* mut being most frequent (n=7). Mut in signaling related genes present at both time points included *NRAS* (G12V/D) and *NF1* mut. At the time of Rel, gene mut frequently referred to signaling (34%) including a *KRAS* (G13D) and a *KIT* (D816V) mut, both in pts with loss of *FLT3*-ITD at Rel.
Summary/Conclusions: Analyzing the clonal evolution of *FLT3*-ITD^{pos} AML, known pre-leukemic mut were stably detectable at Dx and Rel in most pts, whereas known signaling related gene mut were also acquired at Rel. To further investigate more comprehensively pathways underlying therapy resistance with a focus on TKI treatment, larger cohorts of pts are currently analyzed for the detection of recurrent mutational patterns.

E869

MICROENVIRONMENT SECRETED PROTEINS MEDIATE RESISTANCE TO TARGETED THERAPY IN PRIMARY AML CELLS

A. Dokal[1,*], J. Gribben[1], P. Cutillas[1]
[1]Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background: The bone marrow stromal microenvironment (BMSM) plays an important role in the pathophysiology of acute myeloid leukemia (AML). This is demonstrated by primary AML blasts dependence on stromal conditioned media to survive long-term in culture. Although some of the components of the stromal secretome (the totality of secreted proteins by biological cells) that augment AML survival are known, the precise molecular mechanisms of the stromal-blast interactions are not fully defined.
Aims: i) Identify proteins secreted by bone marrow stromal cells that mediate AML survival; ii) Investigate global changes in signalling pathway activity induced by stromal factors in primary AML; iii) Validate the functional significance of these interactions through targeted inhibition of BMSM activated signalling pathways.
Methods: We used primary AML cells and established cells lines. Four different human AML lines were grown individually or in co-culture with a mouse bone marrow stromal line (MS-5). The resulting conditioned medium from these experiments (4 AML lines alone, 4 AML lines + MS-5, MS-5 alone) was purified to obtain the secretome (in triplicate). Proteins in these secretomes were quantified using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS). Peptide sequence searches against both mouse and human proteomes allowed for discrimination between the mouse stromal and human AML proteins. Guava EasyCyte Flow Cytometry was used to measure the viability and proliferation of these cell populations, assessing the capabilities of the identified factors above on primary AML cells (n=6) as well as the effects of kinase inhibitors Torin-1, Trametinib, Tofacitinib and Midostaurin over 72hrs with and without stromal conditioned media (n=10). Label-free LC-MS/MS based phosphoproteomics quantified >5,000 phosphorylation sites in primary AML patient cells treated with identified stromal factors individually and combined in triplicate. Commercial (MASCOT) and in-house (PESCAL, KSEA) software were utilised to identify and quantify proteins, determine kinase activities and interpret intracellular signalling.
Results: Initially by comparing secretomes of the four AML lines (on their own or in MS-5 co-culture) we identified 520 bone marrow stromal proteins and 293 AML blast proteins. From these, six stromal proteins were selected (including S100-A11, connective tissue growth factor [CTGF] and bone morphogenic protein-1 [BMP-1]) based on their ability to effect growth and likely signalling capacity in AML cells. These six proteins were used in varying combinations to determine their effect on growth of primary AML cells from patients (n=6). We also analysed the phosphoproteomes of primary AML cells displaying the maximal effects on growth in response to the six factors above to determine the underlying biological mechanisms. These studies have shown that several different pathways are activated as a result of secretome treatment including mTOR and MAPK. Primary AML cells were sensitive to targeted inihibition of these pathways. However, the inclusion of stromal secreted factors to the same AML cells would induce sensitivity towards another kinase inhibitor and insensitvity towards the previously effective inhibitor.
Summary/Conclusions: This proteomic approach has allowed identification of a panel of key proteins (including S100-A11, CTGF, BMP-1) secreted by the stromal cells that modulate cell signalling and cell fate in AML blasts. Using a proteomic approach to study growth factor effects we were able to dissect the factor specific effects on AML signalling. Subsequent survival assays and targeted inhibition studies demonstrate that despite heterogeneity in patient response to these factors, activity in key signalling pathways such as MAPK and mTOR switch under stromal influence. These observations suggest that resistance to targeted therapies *in vivo* in part may arise from changes that AML cells induce in the microenvironment.

CHARACTERIZATION OF FLT3 MUTATIONS AT DIAGNOSIS, REFRACTORY DISEASE OR RELAPSE IN AML PATIENTS TREATED WITH MIDOSTAURIN WITHIN THE CALGB 10603 (RATIFY) AND AMLSG 16-10 TRIALS

L.K. Schmalbrock[1,*], F. Theis[1], L. Bullinger[1], D. Weber[1], V.I. Gaidzik[1], P. Paschka[1], M.-V. Teleanu[1], W. Fiedler[2], H. Salih[3], G. Wulf[4], U. Germing[5], M. Lübbert[6], F. Thol[7], M. Heuser[7], R.A. Larson[8], A. Ganser[7], R.F. Schlenk[19], R.M. Stone[10], H. Döhner[1], K. Döhner[1]
[1]Klinik für Innere Medizin III, Universitätsklinikum Ulm, Ulm, [2]II. Medizinische Klinik und Poliklinik, Universitätsklinikum Hamburg, Hamburg, [3]Klinik für Innere Medizin II, Universitätsklinikum Tübingen, Tübingen, [4]Klinik für Hämatologie und Medizinische Onkologie, Universitätsklinikum Göttingen, Göttingen, [5]Klinik für Hämatologie, Onkologie und Klinische Immunologie, Universitätsklinikum Düsseldorf, Düsseldorf, [6]Klinik für Innere Medizin I, Universitätsklinikum Freiburg, Freiburg, [7]Klinik für Hämatologie, Hämostaseologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule Hannover, Hannover, Germany, [8]Department of Medicine and Comprehensive Cancer Research Center,

University of Chicago, Chicago, IL, United States, [9]Nationales Centrum für Tumorerkrankungen, Universität Heidelberg, Heidelberg, Germany, [10]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) and mutations (mut) in the tyrosine kinase domain (TKD) of the receptor tyrosine kinase *FLT3* occur in about 25% of acute myeloid leukemia (AML) patients (pts). *FLT3*-ITD is associated with an unfavorable prognosis in particular in pts with a high allelic mutant to wildtype ratio (AR;>0.5) as well as localization of the ITD in the beta1-sheet of the receptor. FLT3is targetable by tyrosine kinase inhibitors (TKI) and the combination of chemotherapy with the TKI midostaurin has been recently investigated within the CALGB 10603 RATIFY trial and is still under investigation within the AMLSG 16-10 trial.
Aims: To study the *FLT3*^{mut} status at the time of diagnosis (Dx), refractory disease (RD) and relapse (Rel) in AML pts treated within the CALGB 10603 (RATIFY, NCT00651261) and AMLSG 16-10 (NCT01477606) trial with regard to AR of *FLT3*-ITD and *FLT3*-TKD^{mut}, loss of *FLT3*-ITD and *FLT3*-TKD^{mut} and change of ITD clones (ITD insertion site, length, number of clones).
Methods: *FLT3*-ITD and *FLT3*-TKD^{mut} were detected using Genescan-based fragment-length analysis according to standard protocols. In the randomized phase-III RATIFY study, *FLT3*^{mut} pts were treated with induction (daunorubicin/cytarabine) and consolidation (high-dose cytarabine) plus midostaurin or placebo, followed by maintenance therapy with midostaurin or placebo for 1 year. The phase-II AMLSG 16-10 trial evaluates midostaurin in induction, consolidation (allogeneic hematopoietic cell transplantation or high-dose cytarabine) and maintenance therapy in *FLT3*-ITD positive pts.
Results: In total, 83 pts were analyzed, of which 33 were treated in the RATIFY and 50 within the AMLSG 16-10 trial. 36 pts had RD and 47 pts had relapsed. *FLT3*-ITDwas present at diagnosis in all pts treated in the AMLSG 16-10 trial; one pt had an additional *FLT3*-TKD^{mut}. Pts entered in the RATIFY trial had either a *FLT3*-ITD (n=22), a *FLT3*-TKD^{mut} (n=9), or both (n=2). The median AR of *FLT3*-TKD^{mut} at Dx was 0.82 (0.07-2.66) and the majority of pts showed loss of *FLT3*-TKD^{mut} at RD or Rel (n=9/12; 75%). In relapsed pts, loss of *FLT3*-ITD occurred in 14 (36%) pts. There was no significant difference between the median *FLT3*-ITD AR at Dx [0.62 (0.10-18.94)] and Rel [0.65 (0.07-38.75); p=.98]. A shift of the ITD clone was found in 14 (36%) pts at Rel, with switch of the ITD insertion site or length in 8 (21%) pts. 8/14 pts with change of the ITD clone at Rel had multiple ITD clones at Dx. For 35 *FLT3*-ITDpositive pts with refractory AML, *FLT3*-ITD loss was observed in 17 (49%) pts. The median AR of *FLT3*-ITD was significantly lower at the time of RD [0.29 (0.05-2.37)] compared to Dx [0.58 (0.05-8.91); p=.002]. The ITD clone changed in 5 (14%) pts with RD. In pts with shift of the ITD clone at RD (n=5) or Rel (n=14), no significant difference of the median ITD length was observed (p=.84).
Summary/Conclusions: Comparing the *FLT3*-ITD status at Dx, at the time of RD or Rel, we found a lower median AR of *FLT3*-ITD in pts at RD compared to Dx, whereas no significant change of AR was observed at Rel. In addition, loss of *FLT3*-ITD was observed in 49% of pts at RD and in 36% of pts at Rel. These findings suggest that the *FLT3*-ITD clone can be targeted in a significant number of pts and other clones might mediate resistance to treatment. We also observed a switch of the ITD clone in about 20% of pts with Rel, indicating the presence of ITD subclones at the time of Dx that might confer resistance to treatment. Despite the small number of TKD mutations in our study, it was remarkable that most of the TKDs (75%) were lost at the time of RD or Rel.

E871

A NOVEL PML-RARG FUSION IN ACUTE PROMYELOCYTIC LEUKEMIA

J.-S. Ha[1,*], C.-S. Ki[2], C. Lee[3], D.-H. Kim[1], Y.-R. Do[1], W.-M. Lee[1], N.-H. Ryoo[1], D.-S. Jeon[1]
[1]Keimyung University School of Medicine, Daegu, [2]Sungkyunkwan University School of Medicine, [3]Samsung Genome Institute, Seoul, Korea, Republic Of

Background: Acute promyelocytic leukemia (APL) is a unique subtype of acute myeloid leukemia (AML) characterized by specific translocation involving retinoic acid receptor alpha (*RARA*) locus. Retinoic acid receptor (RAR) is a member of nuclear receptor family, and has three types of isoforms such as RARA, reinoic acid receptor beta (RARB) and retinoic acid receptor gamma (RARG). These RARs share high structural homology (90%). Although the oncogenic properties of the artificial *PML-RARG* fusion gene was observed in an *in vitro* study, there has been no report on the *PML-RARG* fusion in human APL patients.
Aims: We report here a novel *PML-RARG* rearrangement in a patient with AML displaying suitable morphologic and immunophenotypic features of the classic hypergranular APL.
Methods: Whole genome sequencing (WGS) and further analysis of mRNA and gDNA were performed to clarify the atypical gene rearrangement observed by karyotyping and FISH.
Results: Laboratory, morphology and immunophenotypic analysis results suggested the classic APL with hypergranular type. A clonal translocation t(12;15)(q13;q22) was identified by karyotyping. No evidence of fusion of *PML-RARA* was detected by RT-PCR and *PML*-split was found on FISH analysis using *PML-RARA* dual color dual fusion probes. WGS analysis performed to clarifying the partner gene of *PML* located on chromosome 12q13 strongly suggested a *PML-RARG* fusion. RT-PCR following sanger sequencing were performed to verify the presence of *PML-RARG* fusion transcript, then two kind of transcripts was detected, one with the fusion of *PML* exon 3 and the middle part of exon 1 of *RARG* and the other with the fusion of *PML* exon 3 and exon 2 of *RARG*. The breakpoint of DNA was clarified on intron 3 of *PML* and 5' region of *RARG*. Despite of ATRA treatment for 9 days, cell count did not show any response. Then induction chemotherapy composed of idarubicin and cytarabine was combined on ATRA. ATRA was finally stopped after 18 days, then cytogenetic remission was acquired day 36 after induction therapy.
Summary/Conclusions: We first report the presence of *PML-RARG* fusion in a human APL patient. This report supports the possibility of a new molecular mechanism involving *RARG* not *RARA* in APL and suggests the need of different therapeutic approach for this variant case showing the potential ATRA resistance.

E872

COOPERATION OF MLL-PTD WITH DNMT3A OR RUNX1 MUTATIONS IN AML LEUKEMOGENESIS

H.-W. Kao[1,*], R. Bera[2], Y.-J. Huang[2], J.-F. Fu[2], D.-C. Liang[3], L.-Y. Shih[1]
[1]Chang Gung Memorial Hospital and Chang Gung University, [2]Chang Gung Memorial Hospital, Taoyuan, [3]Mackay Memorial Hospital, Taipei, Taiwan, Republic of China

Background: Our previous study showed that *DNMT3A* or *RUNX1* mutations were frequently coexisted in the *MLL*-PTD AML patients (Oncotarget 2015).
Aims: We aimed to investigate the role of coexisted *DNMT3A* or *RUNX1* mutations in leukemogenesis of *MLL*-PTD AML.
Methods: After lentiviral-mediated over-expression of *RUNX1* or *DNMT3A* mutants in *MLL*-PTD mouse bone marrow (BM) cells or human *MLL*-PTD^{+} AML cell lines, colony formation, cell proliferation, differentiation and apoptosis assays were carried out. Interaction of RUNX1, HIF-1α, and MLL-PTD were evaluated by co-immunoprecipitation assay. Differential genes and protein expression, histone modifying protein expression, and enrichment of histone-4 acetylation (H4Ac) were assessed by RT-qPCR, Western blot, and ChIP-qPCR, respectively. For BM transplantation assays in mice, *MLL*-PTD^{+} BM cells over-expressing *DNMT3A*-wild type (Wt)/mutants and empty vector (EV) control were injected into C57BL/6 mice via tail vein.
Results: We observed that *MLL*-PTD mouse BM cells with *RUNX1* mutants lacking C-terminal VWRPY sequence (H377fsX and V425fsX576) had increased self-renewal, proliferation, increased HIF-1α and its downstream gene expression. In addition, the interaction of HIF-1α and MLL-PTD was disrupted in the cells transduced with C-terminal truncated RUNX1 mutants or *RUNX1* shRNA. Compared with those expressing *DNMT3A* mutants, over-expression of *DNMT3A*-Wt reduced cell growth, colony formation and self-renewal activities of EOL-1 and *MLL*-PTD^{+} BM cells. All *DNMT3A* mutants impaired Na-butyrate-induced differentiation, but only R882H mutant impaired ATRA-induced differentiation *in vitro*. *DNMT3A* mutations were associated mostly with up-regulation of *homeobox B* (*HOXB)* genes. The expressions of *BCL2A1*, *AREG, PRKCA, HLX, hBEGF* and *MCL1* were increased in the *DNMT3A*-mutant cells compared to those of *DNMT3A*-Wt. Cells with *DNMT3A* mutants showed a reduction of H4Ac enrichment at the *HOXB* and *HOXC12* promoter regions compared to the control cells or the cells with *DNMT3A*-Wt. DNA methylation microarray analysis identified both hypo- and hypermethylation features in different regions throughout the whole genome of *DNMT3A* mutants-transduced EOL-1 cells. Up-regulated genes including *HLX* and *hBEGF* were hypomethylated in the EOL-I cells transduced with *DNMT3A* mutants. *In vivo* study showed that white blood cells including neutrophils, lymphocytes and monocytes increased significantly (P<0.03) in the *DNMT3A*-mutants mice compared to EV or Wt- mice at 10 months post-BM transplantation.
Summary/Conclusions: The present study showed that both *RUNX1* and *DNMT3A* mutants dysregulated self-renewal, proliferation and apoptosis in the mouse *MLL*-PTD BM cells. Disruption of MLL-PTD-RUNX1-HIF-1α complex in the *RUNX1*-mutant and aberrant methylation in the *DNMT3A*-mutant cells might play an important role in AML pathogenesis. Our results showed that cooperative *RUNX1* or *DNMT3A* mutations had impact on leukemogenesis of *MLL*-PTD AML.

AML BLASTS INDUCE A SENESCENT PHENOTYPE IN THE BM-MSC THROUGH THE UPREGULATION OF P21

E. Forde[1,*], A. Abdul-Aziz[1], T. Mehta[2], F. Di Palma[2], C. Ingham[3], M. Lawes[4], K. Bowles[14], S. Rushworth[1]
[1]Norwich Medical School, University of East Anglia, [2]Earlham Institute, [3]Department of Trauma and Orthopaedic Surgery, NNUH, [4]Department of Haematology, Norfolk and Norwich University Hospital NHS Trust, Norwich, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous clonal disorder that arises from the haematopoietic myeloid progenitor cells within the

bone marrow microenvironment (BMM). Survival of patients with AML is presently poor; two-thirds of younger adults and 90% of older adults die of their disease. Even in patients who achieve remission with chemotherapy, relapse is common and occurs from minimal residual disease sequestered in protective niches in the BMM. Reciprocal interactions between that of the AML and bone marrow mesenchymal stromal cells (BM-MSC) are central to the survival and progression of the leukaemic blasts through micro-environmental promotion of quiescence in malignant cells as well as the activation of anti-apoptotic and pro-survival pathways.
Aims: To investigate how BM-MSC are programmed by AML to generate a pro-tumoural environment.
Methods: Primary AML and BM-MSC were isolated from the pelvis of AML patients following informed consent and under approval from the UK National Research Ethics Service (LRCEref07/H0310/146). Low input RNASeq of 10 AML BM-MSC and 10 healthy BM-MSC (taken from the pelvis of patients undergoing elective hip replacement surgery) was performed following CD271 MicroBead selection. Primary AML blasts $1x10^6$ were co-cultured on confluent primary BM-MSC for 48 hours (h), 72h and 168h. Real-time PCR was used to verify the RNA sequencing data and Western Blot analysis to confirm protein expression. Lentivirus mediated knockdown was used to target gene expression in the BM-MSC. Senescence was assayed by β-Galactosidase staining.
Results: Results from the RNA sequencing carried out to compare 10 healthy and 10 AML BM-MSC show that 1125 genes were differentially expressed, with 924 down-regulated in AML derived BM-MSC and 201 up-regulated. From this analysis, we found that CDKN1A (p21) is up-regulated in BM-MSC from AML patients (7.406 logFC) compared to BM-MSC from patients with normal bone marrow. Further analysis of p21 mRNA expression confirmed an increase in AML BM-MSC compared to normal BM-MSC. In-vitro experimentation showed that p21 mRNA and protein expression is increased in BM-MSC when co-cultured with primary AML. Furthermore, we show that AML increased senescence β-Galactosidase staining in BM-MSC and that p21 knockdown in BM-MSC reversed the senescent phenotype. Finally, primary AML cultured on p21 knockdown BM-MSC had reduced survival compared to control BM-MSC.
Summary/Conclusions: We have identified that AML induces a senescent BM-MSC niche via the p21 mediated pathway which in turn promotes survival and proliferation of AML. Silencing of p21 within the BM-MSC reduces AML survival. In identifying this novel microenvironment feedback loop in AML we highlight a potential new target for future AML therapies.

E874

HYPOXIA DRIVES AML PROLIFERATION IN THE TUMOR MICROENVIRONMENT THROUGH HIF1A/MIF SIGNALLING

A. Abdul-Aziz[1,*], M. Shafat[1], C. Marlein[1], R. Piddock[1], S. Robinson[2], D. Edwards[1], Z. Zhou[1], A. Collins[3], K. Bowles[1,3], S. Rushworth[1]
[1]Norwich Medical School, [2]School of Biological Sciences, University of East Anglia, [3]Department of Haematology, Norfolk and Norwich University Hospitals NHS Trust, Norwich, United Kingdom

Background: The bone marrow microenvironment is hypoxic and furthermore hypoxia contributes to the development and maintenance of acute myeloid leukemia (AML) cells within the bone marrow microenvironment. The hypoxic state is principally maintained by members of the hypoxia-inducible factor (HIF), in particular HIF1a and its target genes, including MIF. We have previously shown that AML cells express constitutively high macrophage migration inhibitory factor (MIF) which drives IL-8 expression by the BM-MSC which in turn supports AML cell survival and proliferation (Abdul-Aziz et al, 2017).
Aims: The aim of the present study is to determine the role of hypoxia in regulating MIF signalling in AML.
Methods: Primary AML were isolated from the bone marrow and peripheral blood of AML patients following informed consent and under approval from the UK National Research Ethics Service (LRCEref07/H0310/146). Differential expression analysis of RNA sequencing data (GEO ID: GSE49642) was used to compare hypoxia-associated gene expression of BM AML blasts with AML blasts obtained from the peripheral blood (PB). AML cell lines and primary AML blasts were cultured under normoxic (20% oxygen) or hypoxic conditions (1% oxygen). MIF mRNA expression was determined by RT-PCR and protein was determined using target specific ELISA. HIF1a protein expression was determined by western blotting. Lentiviral-knockdown of MIF and HIF1a were performed on AML blasts prior to in-vivo xenograft mouse model injection. Finally, in-vivo analysis of the MIF inhibitor, ISO-1, was performed in the AML xenograft model.
Results: Our results show that MIF gene expression was significantly higher in AML samples from the BM compared to those from PB. To determine If MIF is regulated by HIF1a in AML cells, we mimicked the hypoxic conditions of the BM using $CoCl_2$, DFO and a hypoxic chamber. We found that 1% O_2, $CoCl_2$ and DFO upregulate MIF transcription and protein expression in OCI-AML3 cell lines and in primary AML blasts. Lentiviral mediated KD of HIF1a decreased MIF expression in human AML cells and significantly reduced leukaemic proliferative capacity. Moreover, KD of HIF1a in OCI-AML3 significantly increased survival of NSG mice compared to control-KD. Finally, in-vivo lentiviral mediated knockdown of MIF and pharmacological targeting of MIF using ISO-1 significantly increased survival of AML xenografts.
Summary/Conclusions: The results reported here suggest that hypoxia significantly affects the expression of the pro-tumoural cytokine MIF in AML blasts and that this hypoxia regulated HIF1a/MIF axis supports AML blast survival in the bone marrow niche.

BONE MARROW ECOLOGICAL COLLAPSE IN ACUTE MYELOID LEUKEMIA IS MEDIATED BY REMODELING OF ENDOSTEAL VESSELS

D. Duarte[1,2,*], E.D. Hawkins[1], O. Akinduro[1], H. Ang[1], K. De Filippo[3], M. Haltalli[1], N. Ruivo[1], T.S. Weber[4], R. Khorshed[1], C. Pirillo[1], S. Ramasamy[5], L.E. Purton[6,7], K. Duffy[4], R.H. Adams[8], L.M. Carlin[3,9], C. Lo Celso[1,2]
[1]Department of Life Sciences, Imperial College London, [2]The Francis Crick Institute, [3]National Heart & Lung Institute, Imperial College London, London, United Kingdom, [4]Hamilton Institute, Maynooth University, Dublin, Ireland, [5]Institute of Clinical Sciences, Imperial College London, London, United Kingdom, [6]Stem Cell Regulation Unit, St Vincent's Institute of Medical Research, [7]Department of Medicine, The University of Melbourne, Fitzroy, Australia, [8]Max Planck Institute for Molecular Biomedicine, Department of Tissue Morphogenesis, Munster, Germany, [9]Cancer Research UK Beatson Institute, Glasgow, United Kingdom

Background: Bone marrow vascular niches have been proposed to support acute myeloid leukemia (AML) growth. However, anti-angiogenic therapies do not improve patient outcome suggesting that a complex relationship between AML cells and the microenvironment influences the disease process.
Aims: We aim to study the complex vascular remodelling occuring during AML progression.
Methods: Using a murine model of AML we performed intravital microscopy to investigate leukemia behavior in the bone marrow.
Results: We show AML is an invasive species causing highly localized disruption of the endosteal stroma and outcompeting non-malignant cells. Particularly affected are endosteal microenvironments containing osteoblastic cells and type H endothelium, typically associated with hematopoietic stem cells (HSCs). In contrast, splenic endothelial cells expand, suggesting *de novo* niches in the spleen could potentially support extramedullary hematopoiesis in leukemia. Intravital microscopy further revealed that the endothelium in AML is more adhesive and permissive to transendothelial migration of hematopoietic cells. Pharmacological intervention known to induce type H endothelium preserved HSCs in endosteal areas of diseased mice.
Summary/Conclusions: Together, these data suggest that AML-induced vascular damage contributes to cell egress from the bone marrow, and that new therapeutic approaches aiming to normalize bone marrow vasculature may support normal hematopoiesis.

E876

CLONAL HETEROGENEITY IN PATIENT-DERIVED XENOGRAFT OF ADULT ACUTE MYELOID LEUKAEMIA

F. Gonzales[1,2,*], P. Peyrouze[2], T. Boyer[2,3], S. Guihard[2], N. Helevaut[3], J. Preudhomme[3], S. Geffroy[3], C. Roumier[3], B. Quesnel[2,4], C. Preudhomme[2,3], M. Cheok[2]
[1]Service d'hématologie pédiatrique, CHU Lille, [2]UMR-S 1172, Inserm, [3]Laboratoire d'hématologie, [4]Service des Maladies du Sang, CHU Lille, Lille, France

Background: Acute myeloid leukaemia (AML) is the most common leukaemia in adults. Currently, despite intensive chemotherapy and bone marrow transplantation, outcome is still dismal. In particular, therapeutic stratification remains suboptimal, which is largely attributed to the clinical and molecular heterogeneity of AML.
Aims: To better characterize and study this heterogeneity, we developed an *in vivo* model of AML using patient derived xenografts (PDX).
Methods: Blasts cells obtained from bone marrow of 45 *de novo* AML were intravenously injected into NOD-scid gamma (NSG) mice. Engraftment was surveyed by chimerism of CD45 (human *versus* murine) by flow cytometry. At sacrifice (peripheral blast count greater than 70% or clinical sign of illness), cells collected from bone marrow and spleen were used to perform targeted sequencing (AmpliSeq, Thermo Fisher Scientific®) and gene expression analyses (HG-U133 Plus 2.0 microarray, Affymetrix®). Bone marrow cells were serially transplanted into secondary and tertiary animals. We then compared mutational and gene expression profiles of patient samples at diagnosis and corresponding PDX samples.
Results: Eighteen out of 45 injected samples (40%) successfully engrafted into mice with a median delay of 2.5 months (range : 26-154 days). Leukaemia infiltration into bone marrow was concordant with peripheral blood and spleen infiltration. Successful xeno-engraftment was linked to younger age (50 *vs* 61 years, p=0.04) and elevated white blood cell counts at diagnosis (132 *vs* 35 G/L, p=0.001). No association was found between engraftment and karyotype or ELN classification. Relapse free survival (RFS) was worse for patients with successful PDX (0.3 *vs* 0.9 years, p=0.017). Despite previous reports suggesting better engraftment of AML harbouring FLT3-ITD mutations, we did not find

a preferential engraftment in the presence of FLT3-ITD mutation (9 of 18). Furthermore, we found that the mutational fraction of 3 out of 4 patients harbouring a FLT3-ITD mutation enriched for this mutation in the primary PDX and then remained stable in subsequent xenotransplantations. Similarly, eight PDX with respective primary AML were analysed by next-generation sequencing (NGS) of 27 AML relevant genes. We found stable variant allele fractions (VAF) among the primary and serial PDX bone marrows and spleens for 50 mutations (6 mutations on average per patient); except for DNMT3A and NRAS mutations, which were lost each for one AML sample at the secondary PDX. Concordantly, gene expression profiles were stable between primary patient sample and serial PDX samples up to the tertiary xenograft.
Summary/Conclusions: NSG mice xenotransplantation may be a clinical relevant model for *in vivo* studies of clonal heterogeneity in AML and may be used as preclinical model to test novel therapies.

E877

COSTIMULATION INCREASES INTRACELLULAR SIGNALLING IN BITE® ANTIBODY CONSTRUCT MEDIATED T-CELL ACTIVATION

L. Pachzelt[1,2,*], C. Krupka[1,2], R. Kischel[3], P. Kufer[3], T. Köhnke[1,2], H. Polzer[1,4], K. Spiekermann[1,4], W. Hiddemann[1,4], M. Subklewe[1,2,4]
[1]Department of Internal Medicine III, Klinikum der Universität München, [2]Laboratory for Translational Cancer Immunology, Gene Center of the LMU Munich, [3]AMGEN Research GmbH, Munich, [4]German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: The CD19/CD3 BiTE® antibody construct, blinatumomab, has been approved in Ph-, relapsed/refractory B-cell precursor Acute Lymphoblastic Leukemia (ALL). Despite the promising response rate of 43% in heavily pre-treated ALL patients, reasons for resistance have not been determined. In contrast to classical T-cell activation, BiTE® antibody construct mediated T-cell activation relies solely on binding to the CD3ε chain of the T-cell receptor (TCR) complex. Resolving the exact mechanism of BiTE® antibody construct mediated T-cell activation is a prerequisite for our understanding of mechanisms of resistance.
Aims: In the present study we characterized the role of costimulation on intracellular signalling in CD33/CD3 BiTE® antibody construct (AMG 330)-mediated T-cell activation.
Methods: We generated a murine cell line stably expressing human CD33 and devoid of human costimulatory molecules (B33). In *in vitro* cocultures, cytotoxicity against B33 cells and the AML cell line MOLM-13 was evaluated by flow cytometry. Activation of downstream signalling pathways was assessed by a phospho-flow cytometry protocol for T-cell recruiting antibodies.
Results: Coculture of B33 cells with CD3+ healthy donor T cells (n=4) resulted in AMG 330 mediated mean cytotoxicity of 58.3%. In contrast, MOLM-13 cells were completely lysed (% specific lysis relative to control B33 *vs* MOLM-13: 58.3±32.9 *vs* 99.9±0.1, n=4), despite comparable CD33 expression levels (CD33 median fluorescence intensity (MFI) ratio: B33 116.1 *vs* MOLM-13 67.6). However through the addition of an anti-CD28 antibody or recombinant human IL-2, cytotoxicity against B33 cells could be restored (% specific lysis AMG 330 *vs* AMG 330 + anti-CD28 *vs* AMG 330 + IL-2: 58.3±32.9 *vs* 82.6±11.1 *vs* 91.3±9.0). At lower E:T ratios (1:4) the additional costimulatory signal also increased AMG 330 mediated cytotoxicity against MOLM-13 cells (mean MFI Ratio of CD80 and CD86 on MOLM-13 cells: 1.4±1.2 and 3.0±1.0 respectively, n=3) (% specific lysis AMG 330 *vs* AMG 330 + anti CD28: 65.1±19.7 *vs* 80.7±16.1, n=3). We next analysed intracellular Akt and Erk phosphorylation levels of T cells after stimulation with AMG 330 or a control BiTE® antibody construct (cBiTE®) and MOLM-13 cells. Crosslinked anti-CD3/anti-CD28 antibodies served as positive control. In the presence of target cells, AMG 330 induced significantly lower Akt and Erk phosphorylation (mean% phosphorylated (p)Akt and pErk 7.9 and 7.6, n=3-5) compared to crosslinked CD3/CD28 antibodies (mean% pAkt and pErk 43.0 and 34.6). However, the combination of AMG 330 and CD28 increased the amount of phosphorylated proteins (mean% pAkt and pErk 11.6 and 11.1), but not to the level achieved by CD3/CD28 stimulation. In the absence of target cells, no Akt phosphorylation was observed upon incubation with AMG 330, suggesting a highly target cell dependent T-cell activation (mean% pAkt with *vs* without target cells: 0.8 *vs* 7.9).
Summary/Conclusions: Our data support the hypothesis that costimulation influences the susceptibility of target cells to lysis by T-cell recruiting antibody constructs. Currently, we are validating our results in a larger cohort using T cells from healthy donors and patients with AML. Furthermore, we will analyse the phosphorylation pattern within different T cell subsets and upon knock out of B7 molecules in MOLM-13 cells. Our results will contribute to the understanding of BiTE® mediated activation of T cells, which is a prerequisite for clinical responses.

E878

ESTABLISHING SINGLE CELL WHOLE EXOME SEQUENCING ANALYSIS AS A DISCOVERY TOOL IN NPM1/FLT3 POSITIVE PEDIATRIC ACUTE MYELOID LEUKEMIA

C. Walter[1,*], C. Pozzorini[2], R. Geffers[3], H. Hanenberg[1], Z. Xu[2], N. von Neuhoff[1], D. Reinhardt[1]
[1]Department of Pediatrics III, University Children's Hospital Essen, Essen, Germany, [2]Sophia Genetics, Saint Sulpice, Switzerland, [3]Helmholtz-Zentrum für Infektionsforschung GmbH, Braunschweig, Germany

Background: AML is a rare hematological disorder in children and adolescents caused by distinct genetic aberrations, which are relevant for leukemogenesis, prognosis and therapy. Although major players in the molecular landscape and clonal evolution of AML have been identified in adults, it remains a major technical challenge to genetically characterize the few leukemic stem cells (LSCs) cells against a noisy background of AML blasts and normal hematopoietic cells.
Aims: The aim of this study was to establish a simple workflow for reliable genetic analysis of single LSCs in pediatric patients with AML, where often limited research material is available.
Methods: For three pediatric AML patients with mutations in the genes NPM1 and/or FLT3, we performed single cell sorting for CD34+ CD38- AML blasts by FACS and subsequently whole genome amplification (WGA) using the REPLIG single cell kit (Qiagen). The amplified single cell DNA and additionally the DNA of the corresponding bulk bone marrow was analysed by exome sequencing (WES). Bulk DNA was additionally evaluated by an amplicon-based sequencing approach targeting 54 genes (TruSight Myeloid Panel, Illumina) associated with myeloid malignancies.
Results: The analysis revealed that the median read coverage obtained in the WES of the five DNAs amplified from the single CD34+ CD38- cells and in the corresponding bulk DNAs from the bone marrow of all three patients was comparable for three out of the five single cells. For three amplified single cell genomes, between 92 and 98% of all reads could be mapped to the human genome, however the median coverage for the two failed single cells was 0. For validation of the WGA quality from single LSC DNA, data from 50 out of 54 genes genes analyzed by both sequencing approaches, WES and TSM Panel, were available for all three patients. The majority of variants detected in the WES bulk data could consistently be found at a comparable variant frequency in the TSM panel data. The variant frequencies in the single cell data from WES were more variable and more variants could not be detected in the TSM panel data derived from bulk DNA. We were able to detect n=79 (66%) out of n=121 somatic variants (SNVs, InDels) present in the patients' AML blasts with all three sequencing approaches. WES readily identified n=103 (85.1%) and n=93 (76.9%) of all 121 variants in the bulk and single cell DNA, respectively. Only n=4 (3.3%) variants were not detected by WES at all. We were able to retrace the NPM1 and FLT3 mutations for each of the three patients in the targeted sequencing approach. However the NPM1 mutations and one FLT3 ITD could not reliably be called in the WES approach due to insufficient coverage.
Summary/Conclusions: In summary, WES of amplified single cell DNA is an excellent discovery tool also in pediatric AML for detecting unique changes in potential LSCs that should be validated by targeted sequencing approach with sufficient read counts for finding of rare events.

E879

RAF KINASE INHIBITOR PROTEIN IS INVOLVED IN THE DEVELOPMENT OF MYELOID SARCOMA

V. Caraffini[1,*], S. Schauer[2], K. Kashofer[2], A. Wölfler[1], G. Hoefler[2], H. Sill[1], A. Zebisch[1]
[1]Division of Hematology, [2]Institute of Pathology, Medical University of Graz, Graz, Austria

Background: Myeloid sarcoma (MS) is a subgroup of acute myeloid leukemia (AML), where leukemic cells invade non-hematopoietic tissues and form solid tumor masses. It may occur as isolated event or simultaneously with leukemic infiltration of the bone marrow (BM). Loss of RAF kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, has recently been described as a frequent event in AML and to be functionally involved in leukemogenesis. Although RKIP has been shown to inhibit the formation of metastases in solid tumors previously, its role in the development of MS is currently unknown.
Aims: In this study, we aimed to delineate the role of the metastasis-suppressor RKIP in the development of MS.
Methods: RKIP protein and mRNA expression was evaluated in formalin-fixed paraffin-embedded biopsies of MS and BM by immunohistochemistry and quantitative real-time PCR (qPCR). Sequence analysis of MS biopsies defined as RKIP loss was carried out from 40ng of total DNA employing Ion Torrent Next Generation Sequencing (NGS). For functional assays, both RKIP overexpression and knockdown was performed in THP-1 AML cells by lentiviral transduction of a FLAG-tagged RKIP expression construct and by RKIP shRNA, respectively. Subsequently, these cells were tested in migration and invasion assays using the Transwell-methodology.
Results: This study comprised 14 patients with MS (MS-group) and 14 patients with AML without any evidence of extramedullary involvement (BM-AML group). Of the 14 cases within the MS-group, MS occurred as isolated event in three cases and concomitantly with systemic AML in eleven cases. Both groups were age- and sex-matched and clinical as well as laboratory values were comparable between them. Most importantly, however, when we measured the protein expression of RKIP in leukemic tissues of these patients (MS biopsies in the MS-group and leukemic BM biopsies in the BM-AML group), we observed a

significant increase of specimens exhibiting loss of RKIP expression in the MS-group (7/14 *vs* 1/14; P=0.0329). Interestingly, RKIP loss in MS specimens of cases with concomitant systemic AML was also present in the corresponding leukemic BM samples, thereby excluding a geographical clonal heterogeneity during MS formation in respect to RKIP expression. We then analyzed RKIP mRNA levels by qPCR and observed that RKIP loss correlated with decreased expression of its mRNA (P=0.041). To gain more insight into the molecular landscape of MS patients with and without RKIP loss, we performed NGS of 39 genes that are recurrently mutated in AML. Interestingly, five out of six (83%) MS patients with RKIP loss demonstrated mutation(s) affecting the RAS-pathway, suggesting a potential functional synergism between these events. Consequently, we performed stable overexpression and knockdown of RKIP in the RAS-mutated THP-1 AML cell line and subsequently studied these cells in functional migration and invasion assays. Importantly, RKIP knockdown increased both migration (relative ratio to control cells [rrtcc] of 193%, P=0.0097) and invasion (rrtcc of 171%, P=0.0197), whereas RKIP overexpression had the opposite effects (rrtcc of 56%, P=0.0036 for migration; rrtcc of 35%, P=0.0037 for invasion).
Summary/Conclusions: Loss of the metastasis-suppressor RKIP is associated to MS and to mutations affecting the RAS signaling cascade. In functional assays employing RAS-mutated AML cells, RKIP knockdown increased both, migration and invasion, thereby indicating a role of RKIP in the development of this condition.

E880

INHIBITING MIR-10A OVERCOMES CYTARABINE-RESISTANCE IN ACUTE MYELOID LEUKAEMIA

T.T. Vu[1,*], K. Wang[1], F. Stölzel[2], G. Ehninger[2], T. Molloy[1], D. Ma[1]
[1]Haematology, St Vincent's Hospital, Sydney, Australia, [2]Medical Clinic and Policlinic I, University Hospital 'Carl Gustav Carus', Dresden, Germany

Background: Chemoresistance is the principle cause of treatment failure in acute myeloid leukaemia (AML) despite a promising response to induction chemotherapy. Emerging evidence suggest the roles of autophagy, a self-eating process contributing to chemoresistance of leukaemia cells. We previously demonstrated that miR-10a, highly expressed in a subgroup of AML harbouring Nucleophosmin1 mutations, promotes cell survival by inhibiting non-canonical cell death pathway, suggesting its function in autophagy and thus chemoresistance in AML.
Aims: We aim to demonstrate evidence that miR-10a, a regulator of autophagy, plays important roles in chemoresistance in acute myeloid leukaemia.
Methods: Apoptosis and proliferation in miR-10a inhibited and overexpressed leukaemia cells after cytarabine treatment was measured by Annexin V binding and MTT assay. Autophagy was measured by monitoring the levels of LC3I/LC3II proteins, autophagy-related proteins via Western Blotting and monodansyl-cavaradine (MDC) staining (flow cytometry).
Results: First, we observed a decreased expression of miR-10a in the leukaemia cells after the exposure to stress induced by serum starvation. Overexpressing miR-10a in miR-10a low MV4-11 cells decreased apoptosis induced by nutrient starvation and resulted in the resistance to cytarabine. In contrast, its inhibition in OCI-AML3 cells, which express high miR-10a constitutively, resulted in the induction of apoptosis and increased chemosensitivity towards cytarabine. miR-10a was shown to directly downregulate key members of the p53-mediated tumour suppressor gene network, including the CDKN1A (p21) inhibitor Transcription Factor AP2-gamma (TFAP2C). The inhibition of either miR-10a itself or CDKN1A by siRNA treatment inhibited autophagy induced by serum starvation, treatment with autophagy inducer,mg132 or p53 stabiliser, Nutlin3a.
Summary/Conclusions: The data suggests miR-10a as an important regulator of autophagy via modulation of the p53-p21 tumour suppressor signalling axis in subtypes of AML. It also emphasizes the significance of autophagy in chemoresistance in AML, supporting the targeting of the autophagy pathway as a potential therapeutic approach for AML.

E881

BY AN MCL-1-DEPENDENT MECHANISM, ALVOCIDIB POTENTIATES THE ACTIVITY OF CYTARABINE AND MITOXANTRONE WHEN ADMINISTERED IN A TIME SEQUENTIAL REGIMEN IN AML

H. Haws[1], M. Livingston[1], W. Kim[1], R. Mangelson[1], A. Siddiqui-Jain[1], P. Peterson[1], C. Whatcott[1], S. Weitman[1], D. Bearss[1], S. Warner[1,*]
[1]Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: Treatment with alvocidib has shown significant improvements in the complete remission rates in newly diagnosed acute myeloid leukemia (AML) patients when administered before cytarabine and mitoxantrone (ACM regimen) in a randomized Phase 2 study compared to 7+3. Although the mechanism of alvocidib action as a single agent is documented, the mechanism underlying synergy found in the ACM regimen is not fully understood. The ACM regimen was originally developed based on the perceived benefit of a time-sequential regimen starting with cell-cycle arrest (alvocidib), followed by release of the cells from arrest and inhibition of DNA replication (cytarabine/mitoxantrone) during S-phase. However, recent reports suggest that the transcriptional repression of key anti-apoptotic proteins (eg., MCL-1) mediated by alvocidib's CDK9 inhibition, may contribute to the activity in the ACM regimen.
Aims: We hypothesized that MCL-1 transcriptional repression constitutes the primary mechanism for the synergism observed with the ACM treatment regimen.
Methods: Following treatment, cell viability and caspase activation, an indicator of apoptosis, were assessed using CellTiter-Glo and Caspase-Glo assays, according to manufacturer protocol. mRNA levels were assessed using RT-PCR. Protein levels were assessed using standard immunoblotting technique.
Results: In this study, we demonstrate that treatment with alvocidib, followed by treatment with cytarabine and mitoxantrone, synergized *in vitro* and correlated with the downregulation of MCL-1 protein and mRNA expression. Indeed, the ACM regimen resulted in a 2.4 or 3.4-fold increase in caspase activity relative to any single agent within the combination in MV4-11 or OCI-AML3 cells, respectively. As has been previously reported, we also observed that increased activity of cytarabine in alvocidib-treated cells corresponded with progression into the S-phase of the cell cycle, following the washout of alvocidib. However, this observation accounted for only a small portion of the inhibition of cell proliferation. This was further confirmed by the observation that CDK4/6 (cell cycle) specific inhibitors, such as palbociclib, did not show synergistic increases in caspase activity following treatment in the same setting. In various AML cell lines treated with MCL-1 siRNA, followed by cytarabine and mitoxantrone treatment, we also observed a synergistic increase in the inhibition of cell proliferation.
Summary/Conclusions: Considering our earlier work showing that MCL-1 dependence predicts AML patient response to the ACM regimen, we propose that MCL-1 repression is the primary mechanism of alvocidib's clinical activity. As MCL-1 also confers resistance to cytarabine, the current study provides additional rationale for the inclusion of alvocidib in the treatment of AML, and in the ACM regimen specifically. Taken together, this data suggests that the ACM regimen may be an effective regimen in treating patients with high-risk AML, because of alvocidib's inhibition MCL-1.

E882

DYSREGULATION IN KEY REGULATOR GENES OF AUTOPHAGY AS A MECHANISM OF THERAPY RESISTANCE AND POOR PROGNOSIS IN ACUTE MYELOID LEUKEMIA (AML): RESULTS FROM MICROARRAY ANALYSIS ON 148 PATIENTS

M.C. Fontana[1,*], G. Marconi[1], C. Papayannidis[2], G. Simonetti[2], A. Padella[2], E. Ottaviani[2], A. Ferrari[2], E. Franchini[2], N. Testoni[2], C. Baldazzi[2], S. Lo Monaco[2], S. Paolini[2], M.C. Abbenante[2], J. Nanni[2], L. Bertamini[2], G. Martinelli[2]
[1]Department of Experimental, Diagnostic and Specialty Medicine, [2]University of Bologna, Bologna, Italy

Background: To date, there are no clear evidences if autophagy can lead to therapy resistance or favor apoptosis in cancer. Autophagy can function as a pro-apoptotic mechanism, or can improve stresses survival clearing damaged mitochondria and proteins accumulation. Levels and activity of pro-apoptotic and anti-apoptotic proteins, particularly BCL-2 and p53, high levels of cAMP, and a complex made by PINK/PARK could play as fulcrum of this yin and yang effect of autophagy.
Aims: Our study aims to define the role of PI3P pathways in AML, and to establish if autophagy could reduce the patients' chance to respond to induction, and to worsen OS.

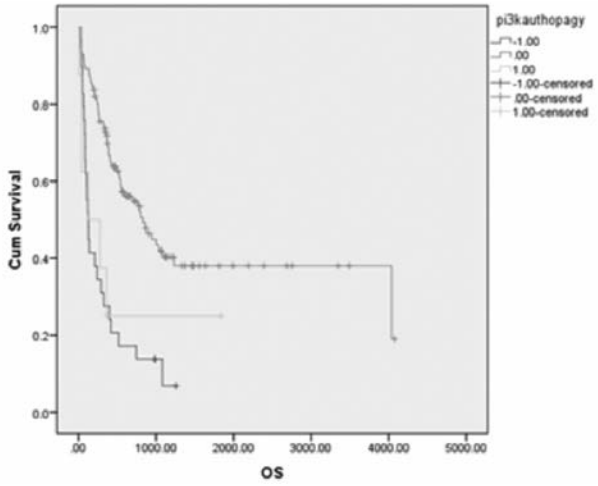

Figure 1.

Methods: We analyzed 148 consecutive newly diagnosed non M3 AML patients treated with induction chemotherapy regimens containing at least one dose of anthracycline. We screened all patients for TP53, FLT3, NPM1 mutations. In all

patients, we perform Microarray-based High-Throughput Technology with Affymetrix SNP array 6.0 or Cytoscan HD. Survival data were collected prospectively from the time of diagnosis, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariate and multivariable regression and Cox Hazard Ratio (HR) model was performed. Correlation between variables was assessed with Fisher's exact test.
Results: Autophagy alteration (gene group 1: *ULK1 CHR11; ULK1 CHR17; BECN1; ATG14; AMBRA1; UVRAG; ATG9A; ATG9B; PIK3C3; PIK3R4*) were related to lower Complete Remission rate (CR%) after induction in univariate (p<.001) and multivariable regression with age, karyotype, secondary AML, *TP53* mutation (p=.014). Autophagy alteration showed to confer worst OS (p<.001) and was significantly associated with complex karyotype and *TP53* mutation (p<.001). We detected significant differences in term of survival independently both in Copy Number (CN) Gain and CN Loss in group 1 genes (p<.001). Furthermore, we investigated genes in **AMPK pathway** (group 2: *SESN1; PRKAA1 CHR 3; PRKAB1: PRKAA1 CHR 1: PRKAG1 CHR11; PRKAG1 CHR 7; PRKAG3; PRKAB1*) and other genes that could be related to a **switch from a physiological role of autophagy to a resiliency mechanism** (group 3: *CCND1; BCL2; PINK1; PARK2; TP53; MDM1; MDM4*): alterations in those genes were shown to confer worst OS (p<.001 in both groups). Alteration in group 2 and group 3 were related to lower CR% after induction (p<.001 in both groups). Whole Exome Sequencing on 56 patients in our set did not found any significant mutation in genes we analyzed with the exception of TP53.
Summary/Conclusions: Our work investigates for the first time with a genomic approach the role of autophagy in AML. We found that both CN gain and CN loss in autophagy key regulator genes are associated with poor prognosis and therapy resistance. A CN loss in autophagy could enhance proliferation and block apoptosis, a CN gain could give cell resiliency, favoring cytoplasm turnover, damaged mitochondria elimination, and neutralizing oxidative damages. Further fucntional studies will be necessary in order to confirm these results.

NO EVIDENCE FOR MICROSATELLITE INSTABILITY (MSI) IN 1,394 PATIENTS (PTS) WITH ACUTE MYELOID LEUKEMIA (AML)

C. Walker[1,*], A.-K. Eisfeld[1], L. Genutis[1], M. Bainazar[1], J. Kohlschmidt[1], K. Mrozek[1], A. Carroll[2], J. Kolitz[3], B. Powell[4], E. Wang[5], R. Stone[6], R. Bundschuh[1], A. de la Chapelle[1], C. Bloomfield[1]
[1]The Ohio State University, Columbus, [2]University of Alabama, Birmingham, [3]Monter Cancer Center, Lake Success, [4]Wake Forest, Winston-Salem, [5]Roswell Park Cancer Institute, Buffalo, [6]Dana-Farber Cancer Institute, Boston, United States

Background: MSI is the addition or loss of bases within repetitive DNA sequences called microsatellites (MSs), caused by defects in DNA mismatch repair. MSI is most often observed in endometrial and colorectal carcinomas, and pts with MSI-positive (MSI$^+$) solid tumors have shown promising responses to therapy with immune checkpoint inhibitors. MSI's existence in AML has been examined in several studies, but the results are equivocal, with some reporting a total absence of MSI and others finding as many as 20% of *de novo* AML pts are MSI$^+$. These studies tested for MSI using polymerase chain reaction (PCR) of small numbers of MSs (usually 5-7), and typically examined <100 pts. To our knowledge, the largest published AML cohort studied for MSI contained 132 pts.
Aims: To screen 1,394 AML pts for MSI.
Methods: Diagnostic DNA samples from 1,371 pts (1,364 with *de novo* AML and 7 with therapy-related AML [t-AML]) and 86 paired germline DNAs were sequenced for 80 genes using amplicon-based next-generation sequencing (NGS). Variants were detected by MuTect and Varscan with variant allele fraction cut-offs of 0.30, and considered mutations if not reported in 1000 Genomes or dbSNP142. NGS-based MSI detection was performed similar to mSINGS (Salipante *et al*., *Clin Chem*. 2014;60:1192) combined with a MS variant caller we previously developed (Walker *et al*., *Hum Mutat*. 2016;37:1004). Briefly, 18 MSs with >50 reads in all samples and that were not polymorphic in germline DNAs were selected from the target panel; then the number of different length MSs (alleles) each AML sample had was calculated for each of the 18 MS loci. Outlier samples with elevated allele counts were flagged for each locus. Based on previously established mSINGS crtieria, samples flagged in ≥20% of MSs (4 out of 18) were considered MSI$^+$. Paired DNAs were separately screened for MSI by comparing the alleles in each AML sample to its paired germline DNA, using the 2xn version of Fisher's exact test to determine significance. The MS PCR analysis system (Promega) was used on any pairs with significant *P*-values (*P*<0.05*)*. 23 additional t-AML cases were screened using PCR-based detection of 4 MSs (BAT25, BAT26, D2S123 and D17S250).
Results: The NGS-based MSI screen showed that 1,303 samples did not have elevated allele counts for any of the MSs, 67 samples had elevated counts for one MS and one sample had elevated counts at 2 MSs. Because none of the samples met the criterion of ≥4 MSs with elevated allele counts, these data indicate that none of the samples are MSI$^+$. Comparison of alleles between the 86 paired AML and germline samples showed no differences in 78 pairs, and small but statistically significant differences in 8 pairs. However, subsequent assessment of these 8 pairs with the MS PCR analysis system proved that none of them were MSI$^+$. Because MSI$^+$ tumors have 10-100 times as many mutations as MS stable (MSI-negative) tumors, we examined the mutation counts in the 1,371 AML samples for the 80 genes on the target panel. Most samples (64%) had 2-4 mutations and the 2 most highly mutated samples had only 9 mutations each. Since any putative MSI$^+$sample would harbor tens if not hundreds of mutations, these data support the absence of MSI in all samples. Finally, because it has been proposed that t-AML might be more prone to MSI than *de novo* AML,we performed PCR-based MSI detection on an additional 23 t-AML cases, and found all were MS stable.
Summary/Conclusions: The absence of even a single MSI$^+$ case within this large cohort provides strong evidence that MSI is non-existent in AML.

SY-1425, A POTENT AND SELECTIVE RARA AGONIST, REPROGRAMS AML CELLS FOR DIFFERENTIATION ALONG DISTINCT LINEAGES, UNCOVERING PD MARKERS FOR CLINICAL STUDIES

M. Mckeown[1,*], C. Fiore[2], K. Austgen[2], E. Lee[1], D. Smith[2], M.L. Eaton[2], A. Volkert[3], C. Murphy[3], K. Stephens[3], C. Fritz[2], T. Lodie[2], E. di Tomaso[1], E. Olson[2]
[1]Translational Medicine, [2]Biology, [3]Clinical, Syros Pharmaceuticals, Cambridge, United States

Background: SY-1425 (tamibarotene) is a potent and selective agonist of the retinoic acid receptor alpha (RARα) transcription factor (TF), currently in a biomarker directed Ph2 clinical study in AML and MDS patients (NCT02807558). A subset of AML and MDS has been found to have RARα pathway activation characterized by a large enhancer at the *RARA* locus (RARA-high) and/or upregulation of IRF8, a TF associated with RARα signaling, forming the basis of SY-1425 sensitive tumor identification.
Aims: We sought to understand how SY-1425 agonism of RARα acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuitry. This characterization could further inform clinical pharmacodynamics markers.
Methods: We analyzed the epigenomic and transcriptional landscape of 66 non-APL AML patients and normal primary myeloid cells by RNA-seq and ChIP-seq for the enhancer mark H3K27ac. AML cell lines were profiled by RNA-seq, ChIP-seq for H3K27ac and RARα, and ATAC-seq with or without SY-1425 treatment. Cell surface marker changes were assessed by flow cytometry.
Results: A subgroup of the patient samples was defined by an SE driving *RARA*, which co-occurred with SEs driving *FOS* and *JUNB,* or *IRF8*. FOS and JUNB form the AP-1 heterodimeric TF known to promote an immature cell state and the interferon regulatory factor 8 (IRF8) pathway has been implicated in AML pathogenesis. Previously reported crosstalk between INF and retinoic acid signaling was supported by the strong induction of interferon gene sets by SY-1425 in IRF8-high AML models. We found that each AML cell line had distinct compositions of lineage factors consistent with cancer initiation from different stages of myeloid development. SY-1425 induced maturation features associated with monocytic, macrophage, dendritic, and granulocytic cell types. While APL has well characterized and specific granulocytic differentiation, we found that RARA/IRF8-high AML could follow multiple differentiation paths depending on the initial state of the AML model, necessitating different marker panels to capture full cell typing. Functional validation confirmed surface marker changes consistent with the observed epigenomic alterations including CD11b, CD11c, CD66b, and CD38 upregulation. We integrated epigenomic data, DNA accessibility, and SY-1425 response to understand RARα agonist perturbation to cell circuitry. Enhancer elements directly bound by RARα were associated with greater response to SY-1425 as were enhancers bound by other TFs involved in myeloid differentiation. The accessibility of RAR elements and IRF motifs were increased and their associated TFs were upregulated. The target genes of known immature/proliferative state drivers, such as RUNX1 and CEBP, were downregulated. Importantly, the FOS/JUN circuit, identified as a component of the oncogenic RARα circuit in patient samples, was found to be suppressed.
Summary/Conclusions: As in normal myelopoiesis, RARα and associated cell state TFs play a critical role in the differentiation of AML. SY-1425 perturbation of this circuitry leads to differentiation toward multiple potential lineage paths depending on the initial state of the cancer. These pharmacodynamic changes can be assessed clinically and combined with common AML/MDS assays, such as blood and marrow aspirate smears or white blood cell differentials, to support the differentiation mechanism of action and offering the potential for early biologically relevant data to inform current and future clinical studies.

Background: Mutations in the *CEBPA* gene are detected in about 10% of patients (pts) with cytogenetically normal (CN) acute myeloid leukemia (AML). *CEBPA* mutations can either be biallelic (bi) or monoallelic (mo). Only pts with bi*CEBPA* mutations have favorable outcomes when compared to other CN-AML pts. bi*CEBPA* mutations are rarely associated with other prognostic mutations like internal tandem duplications (ITD) or mutations in the tyrosine kinase domain (TKD) of the *FLT3* gene or mutations in *NPM1*. There is a specific association of bi*CEBPA* mutations with mutations in the transcription factor *GATA2*.
Aims: In this study we aimed to characterize the mutational spectrum of CN-AML pts with mo- and bi*CEBPA* mutations. We further analyzed the effect of *TET2* and *GATA2* mutations on outcome in pts with bi*CEBPA* mutations.
Methods: Targeted amplicon resequencing (Agilent Haloplex, target region: 63kbp) was used to analyze 42 target genes or hotspots known to be mutated in AML or other hematologic neoplasms.
Results: In 48 bi*CEBPA* and 32 mo*CEBPA* we found mutations in 20 and 26 different genes respectively. Mo*CEBPA* pts had significantly more additional mutations compared to bi*CEBPA* pts (mean: 3.9±1.7 *vs* 2.2±1.5; p<.001). We also compared the mutational profile of mo*CEBPA* and bi*CEBPA* pts with a cohort of 287 wildtype (wt) *CEBPA* pts. Eight genes with a mutation frequency of ≥5% were significantly associated with one or more groups. We confirmed the mutual exclusiveness of bi*CEBPA* and *NPM1* and the association between *GATA2* and bi*CEBPA* (35.4%). *TET2* was frequently mutated in both mo- (43.8%) and bi*CEBPA* pts (41.7%), but not in wt*CEBPA* (16.3%; mo- *vs* wt*CEBPA* p<.001; bi- *vs* wt*CEBPA* p<.001). Mutations in TKD1 or TKD2 of *FLT3* were frequently identified in mo*CEBPA* (25%) and wt*CEBPA* pts (17.8%) but not in bi*CEBPA* pts (2.1%). The *FLT3*-TKD1/2 mutation frequency in bi*CEBPA* significantly differs from mo*CEBPA* (p=0.002) and wt*CEBPA* (p=0.004). There was a significant difference in the frequency of *FLT3*-ITD in bi*CEBPA* (20.8%) *vs* wt*CEBPA* pts (40.8%; p=.009) but not in comparison to mo*CEBPA* pts (43.8%). *IDH2* was found mutated only in wt*CEBPA* (21.6%) and mo*CEBPA* (18.8%). In 48.8% of wt*CEBPA* pts *DNMT3A* was mutated, this significantly differs from bi*CEBPA* pts (14.3%; p<.001) but not from mo*CEBPA* patients (28.1%). *CSF3R* was frequently mutated only in bi*CEBPA* (10.4%) but not in wt*CEBPA* (0.35%; p<.001) or mo*CEBPA* (3.1%; ns). *STAG2* was associated with mo*CEBPA* (25%), while *STAG2* mutations were significantly less frequent in bi*CEBPA* (6.3%; p<.001) and wt*CEBPA* pts (6.27%; p=.002). *TET2* mutations had a negative prognostic impact on overall survival (OS) in biCEBPA pts, but not in mo*CEBPA* pts. OS (HR: 3.1; 95% CI: 1.2-8.2; p=.023) was significantly worse in bi*CEBPA* pts with a *TET2* mutation, but relapse free survival (RFS) and cumulative incidence of relapse (CIR) was not different depending on *TET2* mutational status. In bi*CEBPA* pts we also evaluated the clinical impact of *GATA2* mutations. For 30 of 48 bi*CEBPA* pts survival data was available, 15 of these pts had a *GATA2* mutation. We found no significant difference with respect to RFS (p=0.216), OS (p=0.479) and CIR (p=0.059). In a combined analysis, the *GATA2*mut and *TET2*wt genotype was associated with a lower relapse risk and a trend towards a higher RFS compared to the *GATA2*wt and *TET2*mut genotype.
Summary/Conclusions: bi*CEBPA*, mo*CEBPA* or wt*CEBPA* pts show a distinct profile of co-occurring mutations that might explain the biological differences between these groups. *TET2* mutations were found in 40% of all *CEBPA* mutated pts and might have a prognostic impact in bi*CEBPA* pts.

E886

MECHANISMS OF SYK-MEDIATED SUPPRESSION OF DIFFERENTIATION AND APOPTOSIS IN ACUTE MYELOID LEUKEMIA (AML)

A. Polak[1,*], P. Kiliszek[1], T. Sewastianik[1], M. Szydlowski[1], E. Jablonska[1], E. Bialopiotrowicz[1], P. Gorniak[1], M. Noyszewska-Kania[1], K. Piechna[1], J. Wozniak[2], B. Krzymieniewska[2], E. Lech-Maranda[3], K. Warzocha[3], P. Juszczynski[1]
[1]Department of Experimental Hematology, [2]Department of Diagnostic Hematology, [3]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warszawa, Poland

Background: Spleen tyrosine kinase (SYK) is a critical mediator of integrin b3 signaling in AML, leading to leukemia cell growth and disease initiation upon transplantation into healthy recipients. Genetic or pharmacologic inhibition of SYK leads to increased differentiation, reduced proliferation and apoptosis. However, the comprehensive description of mediators and effectors of SYK signaling in AML is lacking.
Aims: To identify key downstream mediators of SYK signaling in AML responsible for differentiation block, proliferation and leukemic stem cell (LSC) maintenance.
Methods: AML cell lines (KG1, MOLM14) or bone marrow primary AML blasts, were incubated 24h with R406 (1uM, 4 uM) or vehicle. Activity of SYK, ERK, STAT5 was assessed by western blot and/or intracellular phospho-flow. Proliferation, apoptosis and clonogenic potential were assessed by MTS, PI staining and methylcellulose colony-forming assay. Differentiation was assessed by Giemsa-Wright staining, quantitative NBT, CD14/CD15 staining and qPCR. Constitutively active form of MEKDD and STAT5A1*6 were retrovirally transduced to KG1. Activity toward LSC was assessed using leukemia cell line with stem cell properties, TEX. ROS level, mitochondrial mass were assessed by DCF, MitoTracker Green FM staining. Expression of MYC, TFAM, NRF1, NRF2, EF-Tu were assessed by western blot and/or q-PCR.
Results: To identify downstream mediators of SYK in AML, we assessed the activity of key signal molecules in KG1 and MOLM14. AML cells exhibited basal level of pSYK, pERK and pSTAT5. R406 decreased phosphorylation of these proteins, reduced proliferation, clonogenic potential, induced myeloid differentiation and apoptosis. Since ERK can block maturation, we assessed impact of this pathway on differentiation arrest downstream of SYK in KG1 transduced with MEKDD. R406 induced morphological evidence of differentiation and increased expression of myeloid differentiation genes in control cells, whereas in MEKDD transduced cells, R406 had no effect. Given the role of STAT5 in self-renewal of HSC we next assessed impact of this factor on clonogenic potential. R406 reduced clonogenic potential of control cells, while in cells expressing STAT5A1*6, clonogenic potential was maintained. Moreover, STAT5A1*6 cells had significantly higher cell surface expression of an LSC marker, CD25, and R406 reduced CD25 level only in control cells. Since activity of SYK is required for LSC survival, and R406 induced differentiation and reduced CD25 expression, we decided to explore the mechanism of LSC depletion following R406. R406 reduced proliferation, clonogenic potential and induced dose-dependent apoptosis in LSC-enriched TEX cells. Since high pSYK is associated with overexpression of MYC and increased expression of MYC and its targets that drive mitochondrial biogenesis is a characteristic feature of LSC, we hypothesized that R406 deplete LSC by reducing mitochondrial biogenesis/oxidative phosphorylation (OXPHOS). In TEX and primary CD34+ AML blasts R406 reduced expression of MYC, transcription factors associated with mitochondrial biogenesis (NRF1, TFAM, EF-Tu, NRF2), and lowered cellular mitochondrial mass.
Summary/Conclusions: Taken together, we found that SYK inhibition obviates differentiation arrest imposed by ERK activity, and reduces clonogenic potential via decreased STAT5 activity. Moreover, we show that pSYK is required to sustain MYC expression and mitochondrial biogenesis/OXPHOS, a key features of LSC in AML.

MUTATIONAL PROFILE OF RELAPSE-RISK GROUPS IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS

M. Prieto-Conde[1,*], M. Alcoceba[1], C. Jiménez[1], M. García-Álvarez[1], M.E. Sarasquete[1], A. Balanzategui[1], R. Corral[1], L. Marín[1], F. Ramos[2], A. Godoy[3], A. Bárez[4], N.C. Gutiérrez[1], R. García-Sanz[1], M. González-Díaz[1], M.C. Chillón[1]
[1]Hematology Department, University Hospital of Salamanca-IBSAL, SALAMANCA, [2]2Hematology Department, Hospital de León-Ibiomed, León, [3]3Hematology Department, Hospital Miguel Servet, Zaragoza, [4]4Hematology Department, Hospital Nuestra Señora de Sonsoles, Ávila, Spain

Background: Although the fusion oncogene PML-RARA is known to initiate acute promyelocytic leukemia (APL), other cooperating mutations have also been implicated in the disease pathogenesis. However, the spectrum of mutations of APL patients within the relapse-risk groups, based on patient leukocyte and platelet counts at diagnosis, are not yet known
Aims: 1)To identify genetic alterations that might cooperate with PML-RARA in the leukemogenic process within the three APL relapse-risk groups. 2)To find mutations at diagnosis responsible for poor outcome by comparing patients who experiment relapse *vs.* patients who do not relapse in each group.
Methods: We performed multi-amplicon targeted deep sequencing on bone marrow samples of 91 patients diagnosed with APL (PETHEMA LPA99/2005/2012) with a median follow-up of 2.8 years (range 0.2-10) (Table 1). APL patients were classified into relapse-risk groups according to initial leukocyte (WBC) and platelet counts (Score Sanz *et al*. 2000). Libraries were prepared by using the TruSight Myeloid Sequencing Panel (Illumina) that assesses 54 myeloid related genes. Paired-end sequencing runs were performed on a MiSeq (Illumina) genome sequencer. Minimum depth for reliable analysis was fixed in 100x and minimum variant allele frequency (VAF) in 5%. FLT3-ITD mutations were analyzed by fluorescent PCR and capillary electrophoresis. Sequences obtained were analyzed with the Variant Studio v2.1 software (Illumina) and the Integrative Genome Viewer (Genome Browser).
Results: Distribution of 91 patients in the 3 relapse-risk groups was: 28 in low-risk group (31%), 48 in intermediate-risk (53%) and 15 in high-risk (16%). We

found 150 mutations in 31 genes, in 73 out of the 91 patients included (a median of 1 mutation per patient (range: 0-5) with a mean read depth of 10360x. Eighteen patients remained wild-type for all analyzed genes (Figure 1).Only one of this patients suffered relapse (5%). In the global series, no single mutation or functional category showed an association with clinical variables or prognostic impact in terms of overall survival or relapse free survival (RFS). There were no differences in the mean number of mutations per patient in each risk APL group (p>0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28,14%) groups, except for only one patient (1/15, 6%) in high-risk group. FLT3 was the most frequently affected gene in high risk APL subgroup (10 out of 15): 8 patients carried an FLT3-ITD mutation and 2 patients had *amino acid* substitutions at codon *835.* Seven patients assigned to intermediate-risk relapsed (7/38, 18%). All but one carried mutations that have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). By contrast, patients who remain in complete remission in this group, lack mutations with a greater frequency (12/31, 39%). Finally, within the low-risk group 3 patients suffered relapse (3/27; 11.5%) and all of them presented missense mutations in the Ras domain of *NRAS* at diagnosis (p.Ser65Arg & p.Gln61Arg). Therefore, we could identify a small subgroup of patients at a very high risk of relapse (RFS at 5 years, 25% *vs* 100%, p<0.001).

Table 1. Clinical and biological characteristics of 91 APL patients.

Summary/Conclusions: In summary, the present study shows that the mutational status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing a more accurate patient risk classification. Our data suggests the need to search for new mutations required for progression in APL, in order to benefit from a change in post-remission therapy.

E888

ANALYSIS OF THE PD-1/PD-L1 AXIS POINTS TO ASSOCIATION OF UNFAVORABLE RECURRENT MUTATIONS WITH PD-L1 EXPRESSION IN AML

[1]Experimental Hematooncology Department, Medical University of Lublin, [2]Department of Hematology, St. John's Cancer Center, Lublin, Poland, [3]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [4]Department of Rheumatology and Connective Tissue Diseases, [5]Department of Hematooncology and Bone Marrow Transplantation Unit, [6]Department of Human Physiology, [7]Department of Forensic Medicine, Medical University of Lublin, Lublin, Poland

Background: Programmed death ligand-1 (PD-L1) is regulated through miR-34a molecules in AML patients. Moreover, Cortez *et al.* for the first time identified novel, complete mechanism of PD-L1 regulation by p53 via miR-34a in non-small cell lung cancer (NSCLC).
Aims: In this study, our comprehensive analyses of *PDCD1* (PD-1), *CD274* (PD-L1), *TP53* and *miR-34a* expression in AML patients shed new light on the complex regulation of PD-1/PD-L1 axis during development of this disease.
Methods: We performed analysis of *TP53*, *CD274* and *miR-34a* expression in 197 AML patients available from The Cancer Genome Atlas (TCGA) database. Moreover, we assessed mRNA expression of *PDCD1* in independent cohort of 54 AML, 62 MDS and 8 s-AML patients samples using qRT-PCR method. For miRNA analysis, CD33+ cells from 29 AML patients were isolated and *miR-34a* expression was analysed. We also characterized several SNP for *PDCD1* that demonstrate relevant associations with a higher risk of developing autoimmune diseases: PD-1.1 (rs36084323), PD-1.3 (rs11568821), PD-1.5 (rs2227981), PD-1.6 (rs10204525), PD -1.7 (rs41386349), PD-1.9 (rs2227982) in 54 AML, 62 MDS and 100 HVs samples.
Results: We observed significant differences in *PDCD1* expression in groups of 54 AML, 62 MDS, 8 s-AML patients compared to HVs. TCGA data analysis showed that *CD274* expression was elevated in group with *TP53* mutations compared to unmutated *TP53* group (p<0.001). We also found negative correlation of *TP53* and *miR-34a* expression with *CD274* expression (p=0.02 and p=0.005, respectively). The expression of *miR-34a* tended to be elevated in group with high expression of *TP53* compared to group with low *TP53* expression (p=0.17). We have not found any differences in *CD274* expression between groups with or without following mutations: *IDH1*, *TET2*, *RUNX1*, *NRAS*, *CEBPA*, *PTPN11*, *KIT*, *KRAS*, *FLT3*, *DNMT3*, *NPM1* and *IDH2.* Patients with more than 4 recurrent mutations were characterized with higher expression of *CD274* compared to group of patients with 0-3 recurrent mutations. We also found that patients with >14 of all mutations had elevated expression of *CD274* compared to group 0-13 mutations (p=0.06). We observed significant differences in *PDCD1* expression level regarding to PD-1.1.5 polymorphism. Moreover, analysis of a PD-1.1.3 polymorphism in HVs and MDS groups revealed that genotype GG was associated with nearly fivefold lower risk of disease (OR=4.93, p=0.009). We observed significant differences in OS in AML patients in case of presence of certain genotypes of PD-1.1.6. Genotype AA was significant associated with higher risk of shorter OS compared to the rest of the genotypes (58 *vs* 333 days, HR=35; p=0.0188).
Summary/Conclusions: Our analyses indicate that p53 might specifically modulate the tumor immune response by regulating PD-L1 via miR-34a which directly binds to the PD-L1 3' UTR and blocks its expression. Moreover, we found that high *CD274* expression is associated with the higher numbers of recurrent and all mutations as well as poor cytogenetic and molecular risk groups of AML patients. We found significant differences in *PDCD1* expression in AML patients compared to HVs that might indicate deregulation of a signal transduction through the PD-1/PD-1L axis. While our SNP analysis in AML patients suggested a prognostic impact of PD-1. 6 polymorphism, further studies are warranted to evaluate the impact of the PD-1/PD-L1 Axis in AML.

E889

DISSECTING THE DYNAMICS OF SINGLE-TUMOR-CELL-LINEAGES THAT UNDERPIN RELAPSE OF AML

F. Caiado[1], D. Maia-Silva[1], C. Reforço[1], R. Faria[1], B. Silva-Santos[1], H. Norell[1,*]
[1]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: Cancers kill primarily via disease recurrences after transient treatment responses. The emergence of therapy-resistant tumor escape variants is fueled by intra-tumor heterogeneity, underpinned by interference and Darwinian evolution across continuously developing sub-clones in the residual tumor. Several non-genetic factors add significant variation, on top of the diversity provided by the often complex intra-tumor genetic landscape, resulting in an extremely heterogenous and dynamic tumor cell population that can drive disease under many conditions. The relapse of human acute myeloid leukemia (AML) is a prime clinical example of how evolving sub-clonal dynamics can frequently drive treatment-resistant cancer recurrence after initially potent therapeutic responses.
Aims: We aimed to understand how sub-lineage interference is regulated in AML in response to standard and emerging treatments - and clarify how this impacts the development of therapy resistance. Specifically, we aimed to dissect if relapse from each drug regimen was driven by predetermined or stochastically selected sub-lineages and determine the functional impact of such differences.
Methods: We dissected the intra-tumor population dynamics of relapsing AML, beyond the genetic level, by performing single-cell lineage-tracing through cellular barcoding technology (lentivirus-integrated non-coding DNA-tags). We

specifically evaluated the impact of *in vitro* exposure of a barcoded AML cell line (HEL) to chemotherapy regimens (doxorubicin (DOX) and/or cytarabine (CYT)) and/or the hypomethylating agent decitabine (DCT) by comparing the barcode composition of the tumor population recurring after each therapy, *versus* non-treated (NT) controls. By comparing the barcode architectures between parallel replicate cultures for each therapy, we could further delineate whether AML relapse was driven by predetermined (if recurrent barcodes found in multiple replicates) or stochastically selected (if mainly diverse barcodes in each replicate) cells in response to each treatment regimen.
Results: Only treatment regimens containing DOX caused marked decreases in HEL cell numbers and barcode architectures diverging strongly from the non-treated control cultures. Replicate AML cultures regrowing after treatment with DOX all converged to a very similar barcode architecture, reflecting that relapse following this mono-therapy was driven by predetermined single-cell lineages. Combination of DOX with CYT increased the degree of overall cell elimination by ~10-fold, while addition of DCT to either chemotherapy regimen had minimal quantitative impact (*i.e.* yielded similar cell number reductions and re-growth kinetics). Interestingly, DCT additions nevertheless qualitatively changed which sub-lineages that regrew - specifically making replicates more divergent from each other, indicating a more stochastic selection of the cells emerging when DCT had been added to the respective chemotherapy regimens. Importantly, this effect was accompanied by the reversion of resistance to chemotherapy re-treatment, which the DOX-containing treatment regimens potently induced in the absence of DCT.
Summary/Conclusions: The development of curative treatment combinations requires deep understanding of how non-genetic factors synergize with cancer genetics to drive intra-tumor heterogeneity, which is key for tumor escape/ disease recurrence. Our detailed analyses of the heterogenous dynamics among single-cell lineages in AML, following different treatment regimens with apparently similar global impact, represent an important step in dissecting kinship-dependent aspects that go beyond the genetic level. Critically, these studies directly provide the rationale for combining standard chemotherapy with administration of hypomethylating drugs to target AML. The mechanism is prevention of the development of chemotherapy resistance (mediated by selective relapse of a specific set of predetermined sub-lineages) - by partially randomizing which sub-lineages that emerge to drive relapse when DCT is added to the chemotherapies. Maintaining the chemosensitivity of relapsing AML would represent a paradigm shift, turning the currently often lethal recurrences into survivable/ repeatedly clinically manageable episodes of a type of chronic leukemic disease.

MRD ANALYSIS BY NEXT-GENERATION SEQUENCING APPROACH FOR ACUTE MYELOID LEUKEMIA FOLLOW-UP

E. Onecha De La Fuente[1,2,*], I. Rapado[1,2], T. Cedena[1,2], M. Llops[3], Y. Ruiz-Heredia[1,2], J. A. Garcia Vela[4], J. Perez Oteyza[5], A. Figuera[6], F. J. Peñalver[7], E. Barragan[8], M. Gallardo[1,2], J. Martinez-Lopez[1,2], R. Ayala[1,2]
[1]Hematologia traslacional, Hospital 12 de Octubre, [2]Haematological Malignancies Clinical Research Unit, CNIO, Madrid, [3]Instituto de Investigación Sanitaria La Fe, Valencia, [4]Hospital Universitario de Getafe, [5]Hospital Universitario HM Sanchinarr, [6]Hospital de la Princesa, [7]Hospital Universitario Fundación Alcorcón, Madrid, [8]Clinical Pathology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: Sensitive detection of molecular marker of minimal residual disease (MRD) in acute myeloid leukemia (AML), could improve prognostication of a possible relapse during the remission. Traditional methods for measuring minimal residual disease (MRD) in AML, such as real time PCR and multiparametric flow cytometry (MFC) are associated with high technical complexity, low applicability and laborious standardization. However, some patients who achieve a negative MRD become to relapse and several MRD- patients have a long survival, which indicates that the sensitivity and specificity of traditional techniques for MRD assessment can be improved.
Aims: To detect minimal residual disease in AML follow-up sample using high-throughput sequencing as a standard and accurate technique.
Methods: We studied 54 *gDNA* bone marrow follow-up samples (27 after induction, 10 after first consolidation, 17 after second consolidation) from 30 AML patients treated according *PETHEMA AML* clinical protocols and with DNA sample at diagnosis. All patients had achieve CR at the moment of MRD assessment. We developed a custom-targeted sequencing panel of 32 genes *(Ion Torrent Proton System-Thermo Fisher*) for mutation (SNV and/or InDels) detection at diagnosis sample; From the 32 genes, we use specific primers to amplify the specific region of the four most frequent alterations at diagnosis (Samples at follow-up: *FLT3no-ITD n=2, NPM1n=46, IDH2 n=9* or *IDH1 n=7)*. We analysed and detected at diagnosis and at follow-up (after induction, first consolidation or second consolidation), and sequenced with high-throughput approach. We achieve a technical sensibility around $10^{-4}$for point mutations and $10^{-5}$for Indels mutations according our specificity and sensitivity calibration curves.
Results: We analyse the results of assessing MRD by NGS, and the presence or absence of MRD was established at a cut-off level of 0.0017 (between $10^{-4}$and 10^{-5}technical sensibility) by ROC curve with a sensibility of 0.5 for DFS and 0.571 for OS, and a specificity of 0.92 for DFS and 0.897 for OS; thereby a result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.1%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR= 8.33, 95% CI:1.87-37.15) (see figure 1). These results support the usefulness of MRD evaluation in patients with AML by NGS in the context of molecular biology studies.

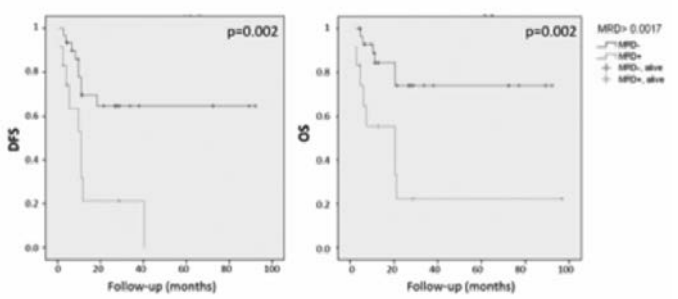

Figure 1. Kaplan-Meier curves for DFS (p=0.002; HR=7.33 95%, CI:1.60-33.51) and OS (p=0..002, HR=8.33 95%, CI:1.87-37.15) of patients with MRD positive (MDR> 0.0017)

Figure 1.

Summary/Conclusions: High-throughput NGS is a technique with the capacity to measure, identify and classified MRD levels. In fact, NGS MRD evaluation has a better DFS and OS prediction than other traditional methods. Implementation of NGS technique on MRD detection could help to anticipate to disease progression.

THE ROLE OF MYELOID-DERIVED SUPPRESSOR CELLS-LIKE BLASTS WHICH SUPPRESS T CELL PROLIFERATION IN LEUKEMIC CELL GROWTH

S. Y. Hyun[1,*], J. I. Lee[1], E. J. Na[1], J.-W. Cheong[2]
[1]Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, [2]Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Myeloid-derived suppressor cells have an ability to suppress T-cell function and have been known to facilitate tumor growth. We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.
Aims: We elucidated the immune suppressive function of leukemic blasts which resembled MDSC phenotype and their role in the growth of leukemic cells.
Methods: $CD11b^+CD33^+HLA\text{-}DR^-$blast (MDSC like blast) were isolated using flow-cytometry from bone marrow mononuclear cells of primary acute myeloid leukemia (AML) patient samples. CD14, CD15, Arg1 and iNOS expression were checked by flow-cytometry to identify the phenotype of MDSC like blast. To evaluate the ability of MDSC like blasts to suppress T cell proliferation, $CD8^+$ T cells from healthy donor and MDSC like blasts were co-cultured with a ratio of 1:1 with/without phytohemagglutinin A 10ug/ml. T-cell proliferation was measured by carboxyfluorescein diacetate succinimidyl ester dilution assay after 3 days of culture. Then, various leukemic cell lines were co-cultured with jurkat T cells and/or MDSC like blasts at a leukemic cell line:jurkat T cell: MDSC like blast ratio of 4:4:1. The effect of jurkat T cells and MDSC like blasts on the proliferation of leukemic cells was assessed by the CCK-8 assay after 1 and 3 days of culture.
Results: MDSCs like blast can be divided into two subtypes, monocytic subgroup expressing CD14 and granulocytic subgroup expressing CD15, and CD14 expression was more frequent than CD15 (67.5% *vs* 39.3%). MDSC-like blasts showed higher expression of Arg1 (77.1% *vs* 38.5%, P<0.001) and iNOS (33.0% *vs* 1.1%, *P*<0.0001) compared to non-MDSC-like blasts. $CD8^+$T cell proliferation induced by PHA was significantly suppressed when co-cultured with MDSC-like blasts compared to without them. Among the various leukemic cell lines, the proliferation of NB4 cells were significantly suppressed when co-cultured with jurkat T cells on day 3 (NB4 23.49±6.26% of control, NB4+jurkat 12.62±3.92%, P<0.01). The decreased proliferation of NB4 cells was partially recovered after 3 days of co-culture with MDSC-like blasts (NB4+jurkat 12.62±3.92%, NB4+jurkat+MDSC like blast 18.71±6.19, P=0.022).

Summary/Conclusions: CD11b^{+}CD33^{+}HLA^{-}DR^{-} MDSC-like blasts subpopulation which expressed the iNOS and Arg1 existed in AML, and showed ability to suppress the T cell proliferation. MDSC-like blasts partially restored the suppressed leukemic cell growth of NB4 cells by jurkat cells. MDSC-like blasts might play a certain role in immune-escape mechanism of AML.

E893

GENERATION OF NEW CELLULAR MODELS FOR THE STUDY OF PEDIATRIC NON DOWN SYNDROME ACUTE MEGAKARYOBLASTIC LEUKEMIA BASED ON HUMAN PLURIPOTENT STEM CELLS

J. Domingo-Reinés[1,*], F. González-Pozas[1], L. Morales-Cacho[1], M. Vogel-Gonzalez[1], G. Rodriguez-Real[1], J. Olmedo-Pelayo[1], R. M. Montes[1], V. Ayllón[1], V. Ramos-Mejía[1]
[1]Genyo, Granada, Spain

Background: Acute megakaryoblastic leukaemia (AMKL) is a rare and complex type of Acute Myeloid Leukaemia (AML), more frequent in children than in adults, characterized by the accumulation of immature megakaryoblasts and thrombocytopenia. Paediatric AMKLs are classified in Down Syndrome AMKL (DS-AMKL) with a good prognosis; and AMKL non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS AMKL due to its low frequency and the heterogeneity of the gene mutations linked to it. Among the genetic alterations found in non-DS-AMKL, approximately half of the patients carry the chromosomal translocations t(1;22) and t(11;12), that generate the fusion proteins RBM15-MKL1 and NUP98-JARID1 respectively, and the inversion of chromosome 16, that originates the fusion protein CBFA2T3-GLIS2.
Aims: It is essential to establish new human models to provide enough biological material for functional and molecular studies. As the genetic alterations that drive infant leukaemia occur in the developing fetus, we propose that human pluripotent stem cells (hPSCs) are ideal models to study non-DS AMKL, as these cells allow us to mimic human embryonic hematopoietic development. In this project, we aim to use human hPSCs expressing non-DS AMKL-associated fusion oncogenes as cellular models for this leukaemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL.
Methods: Generation of human models of non-DS AMKL using hPSCs: 1. Generation of hPSCs with the oncogenic fusion proteins RBM15-MKL1, CBFA2T3-GLIS2 and NUP98-JARID1 using transduction with lentiviral vectors. 2. Generation of hPSCs with the chromosomal translocations t(1;22)(p13;q13) RBM15-MKL1 and t(11;12)(p15;p13) NUP98-JARID1 using the CRISPR/Cas9 system. Once the non-DS AMKL hPSC cell lines are generated, we confirm that they preserve their pluripotency by checking expression of pluripotency markers by flow cytometry and PCR. We also confirm their ability to differentiate into the three germ layers forming embryoid bodies. Using an *in vitro* differentiation system that recapitulates early human haematopoiesis, we compare non-DS-AMKL hPSCs and control hPSCs in order to determine at which point of the differentiation fails and the molecular mechanisms underlying. We analyse by multicolour flow cytometry the generation and evolution over time of different cell populations: mesodermal cells, hemato-endotelial progenitors, hematopoietic progenitors and megakaryocytic precursors. We use colony-forming assays (CFU) to determine the generation and functionality of hematopoietic progenitors.
Results: Here we report the generation and characterization of human non-DS AMKL models based on pluripotent stem cells that express oncogenic fusion proteins RBM15-MKL1, NUP98-JARID1 and CBFA2T3-GLIS2.
Summary/Conclusions: These models will serve as platforms to discover and understand the cellular and molecular alterations caused by these oncogenes, and their impact in the generation of hematopoietic cells during development. With this information we will have a better understanding of the origin and development of paediatric non-DS AMKL, so we will be able to design new therapeutic approaches for these children.

E894

CHARACTERIZATION OF HEMATOLOGIC MALIGNANCIES WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING

L. Johnson[1], M. Bessette[1], A. Berlin[1], J. Haimes[1], D. Fugere[1,*], L. Griffin[1], K. Trifilo[1], N. Manoj[1], H. Wang[1], R. Ryan[2], M. Hussaini[3], B. Kudlow[1]
[1]ArcherDX, Boulder, CO, [2]Massachusetts General Hospital, Boston, MA, [3]Moffitt Cancer Center, Tampa, FL, United States

Background: Hematologic malignancies can be driven by a diversity of mutation types, including single nucleotide variants, copy number variants, gene fusions, insertions and deletions and changes in gene expression profiles. However, comprehensive detection of these mutation types from a single clinical sample is challenging, as specific assays are required to detect each mutation type. Next-generation sequencing (NGS) enables comprehensive detection of all mutation types from whole genomes and transcriptomes. However, low detection sensitivity, high input requirements and high costs render these approaches impractical for routine detection of mutations from clinical sample types. Anchored Multiplex PCR (AMP™) is a target enrichment strategy for NGS that uses molecular barcoded (MBC) adapters and unidirectional gene-specific primers (GSPs) for amplification.
Aims: Our goal was to develop AMP-based NGS assays to simultaneously detect multiple mutation types from DNA and RNA, as well as relative gene expression levels and copy number alterations (CNA) relevant in hematologic malignancies. In particular, we sought to develop methods to detect novel gene fusions, internal tandem duplications (ITDs) and mutations in CEBPα.
Methods: We developed AMP-based Archer® VariantPlex™ and FusionPlex® assays to enable NGS-based detection of mutations from DNA and RNA, respectively. Open-ended amplification permits identification of novel gene fusions with FusionPlex and complex mutation types such as ITDs with VariantPlex assays. MBC adapters ligated to RNA and DNA fragments prior to amplification enable relative gene expression and CNA analysis.
Results: We show instances of gene fusion detection from open-ended amplification in RNA, including a novel fusion, RUNX1-G6PD, in a case of acute unclassifiable leukemia. Furthermore, unidirectional GSPs provided bidirectional coverage of a BCR-ABL1 fusion, which was detected with reads originating from ABL1 as well as BCR. Using our optimized bioinformatics algorithm and the VariantPlex assay, we accurately and reliably detected ITDs of varying sizes and insertion points, with simultaneous point mutation detection, in AML-positive blood samples. Furthermore, we show multiple mutations in various AML-positive sample types, including mutations in CEBPα. Finally, MBCs used in AMP enabled NGS-based expression profiling for identification of Diffuse Large B-Cell Lymphoma subtypes in a small cohort of samples.
Summary/Conclusions: Our results demonstrate that AMP-based NGS enables comprehensive detection of multiple mutation types as well as gene expression levels relevant in hematologic malignancies. Importantly, AMP enables identification of known and novel gene fusions at nucleotide resolution, detection of ITDs and characterization of relative gene expression levels and CNAs.

E895

ASXL1 MUTATIONS IN AML ARE ASSOCIATED WITH SPECIFIC CLINICAL AND CYTOGENETIC CHARACTERISTICS

K. Kakosaiou[1], F. Panitsas[2], A. Ioannidou[1], M. Pagoni[2], P. Apostolou[3], A. Daraki[1], I. Vlachadami[4], T. Marinakis[5], C. Giatra[2], D. Vasilatou[6], C. Sambani[1], V. Pappa[6], K. Manola[1,*]
[1]Laboratory of Health Physics, Radiobiology & Cytogenetics, NCSR "Demokritos", [2]Hematology-Lymphoma Department - BMT Unit, Evangelismos Hospital, [3]Laboratory of Molecular Diagnostics, NCSR "DEMOKRITOS", [4]Department of Pathophysiology, 'Laiko' Hospital, [5]Department of Hematology, "Georgios Gennimatas" General Hospital, [6]Hematology Unit, University General Hospital "Attikon", ATHENS, Greece

Background: Mutations of *ASXL1* are considered early founder events in AML leukemogenesis. They are included in the definition of the "chromatin-splicesome" genomic class of AML and among the high risk genetic prognosticators in the 2017 ELN recommendations.
Aims: We aimed to study the frequency of ASXL1 mutations in a cohort of newly diagnosed AML patients and to look for correlations with conventional cytogenetic findings and baseline characteristics.
Methods: Three hundred and sixty AML patients diagnosed between 2005 and 2014 were studied. Conventional cytogenetic analysis was performed on unstimulated bone marrow cells cultured for 24 and 48 hours. Molecular analysis of *ASXL1* exon 12 mutations was performed by PCR and subsequent direct Sanger sequencing in diagnostic bone marrow or peripheral blood samples.
Results: Median age of the whole cohort was 63 years (11-95) and 56% of patients were male. Eighty two patients (22.8%) had secondary AML (sec-AML) with prior diseases being MDS (63), CMML (4), PV/ET (9), MF (2) and CML (4). Karyotypic analysis was successful in 352 (97.7%) AML samples of which 252 (71.6%) exhibited clonal karyotypic abnormalities. *ASXL1* mutations were detected in 52 patients (14.4%). The most common mutation was c.1934 dupG in 44/52 (84.6%). ASXL1 mutated patients were significantly older with median age 72 *vs* 61.5 years in the unmutated (p=0.0001). Three of 61 patients (4.9%) aged ≤40, 10/97 aged 41-60 (10.3%) and 39/198 aged >60 (19.7%) were mutated (p=0.005). ASXL1 mutation frequency was similar in male (15.4%) and female patients (13.2%). *ASXL1* mutations were significantly more frequent in sec-AML patients (32.9%) than in *de novo* AML (9%, p<10^{-3}). ASXL1^{mut} cases tended to have higher peripheral white cell count at diagnosis (median 29 *vs* 11.5 x10^{9}/L). Frequency of *ASXL1* was similar in patients with normal (13%) and abnormal karyotypes (15.5%) (p=0.55). No association with complex (16.7 *vs* 14.3, p=0.63) or monosomal karyotypes (16.4 *vs* 14.5%, p=0.72) was found. *ASXL1* mutations were less common in patients with WHO defined MDS-related cytogenetic abnormalities (10.5% *vs* 16.6%, p=0.14). Moreover, we observed an inverse relationship of *ASXL1* mutations with -7/del(7q) or -5/del(5q) as a group (8.9% *vs* 16.8%, p=0.07). ASXL1 mutations were significantly more frequent among cases with trisomy 8 (25% *vs* 12.8%, p=0.02) and patients with chromosome 11 aberrations (23.7% *vs* 13.7%, p=0.1).None of the 12 patients with inv(16)/t(16;16) was mutated while 2/16 (12.5%) with t(8;21) had ASXL1

mutations. Moreover, ASXL1 mutations were detected in 3 of 12 patients with aberrations of 3q (25%), 2/9 (22%) with trisomy 13, 2/11 (18%) with t(9;22) and only 1 of 22 patients with t(15;17). Multivariate logistic regression showed that independent predictors of the presence of ASXL1 mutations were older age (OR 1.43 per decade, 95% CI 1.13-1.79), chromosome 11 aberrations (OR 2.69, 95% CI 1.09-6.63), and sec-AML (OR 4.44, 95% CI 2.3-8.57), whereas -7/del(7q) or -5/del5q predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).
Summary/Conclusions: Our results support the association of ASXL1 mutations in AML with advancing age and sec-AML. Association with trisomy 8 did not retain significance in multivariate analysis. Chromosome 11 aberrations emerged as an independent predictor. Despite the strong link with secondary AML (majority of cases post MDS), our data show inverse relationship with -7/del(7q) or -5/del5q. In addition, ASXL1 mutations were not positively associated with MDS-related cytogenetic abnormalities, complex or monosomal karyotypes.

A COMPREHENSIVE DNA TEST FOR THE DETECTION OF TRANSLOCATIONS IN ACUTE LEUKEMIA

E. Van Den Berg-De Ruiter[1,*], M.Z. Alimohamed[1], L.F. Johansson[1,2], E.N. de Boer[1], E. Splinter[3], P. Klous[3], A.G. Bosga[1], M. van Min[3], A.B. Mulder[4], E. Vellenga[5], R.J. Sinke[1], R.H. Sijmons[1], B. Sikkema-Raddatz[1]
[1]Genetics, [2]Genetic Coordination Center, UMCG, Groningen, [3]Cergentis B.V., Utrecht, [4]Laboratory Medicine, [5]Hematology, UMCG, Groningen, Netherlands

Background: Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.
Aims: Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.
Methods: A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia's. TLA was performed on five different cell lines carrying translocations detectable by our panel. [t(12;21), t(6;11), t(11;19)t(8;13), t(6;9), t(17;19)]. Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al, 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the number of target regions as failed. These were not interpreted. Only peaks outside other anchor regions were considered as false positive peaks. Peaks present in other anchor regions were interpreted as possible artefacts and labelled as needing extra confirmation. In these series until now, up to 10% aberrant cells were detected with no false positives as no translocations other than expected for cell lines were detected. Bone marrows of 36 patients suspected of acute leukemia were taken for routine genetic diagnosis (Karyotyping, FISH and or RT-PCR) and TLA. Sample analysis was performed randomized and blinded. TLA outcome was then compared with results from routine genetic testing.
Results: From a total of 36 patients three samples did not meet the required sample quality for further analysis. In the remaining 33 patients our TLA multiplex panel confirmed the presence of translocations on 16 samples. This includes a cryptic translocation involving the *ETV6-RUNX1* fusion gene, t(12;21)(p13;q22) in five pediatric ALL samples, not detected with karyotyping but RT-PCR, confirming the TLA findings. In fifteen samples no translocation was detected, concordant to (cyto)genetic findings. Three translocations were missed due to insufficient sequence reads on the partner chromosome. In addition, in one sample one translocation partner was also missed, located in the telomeric region of the chromosome and therefore resulting to nonspecific mapping of the sequence reads. An additional finding, involving a three way translocation t(9;22;11), missed by cytogenetics was detected by our panel. Two new findings have yet to be confirmed with FISH.
Summary/Conclusions: Our TLA panel showed concordant results for 29 out of the 33 successful sequenced samples. No false positives were found, while an additional translocation was detected. Our panel is able to detect (cryptic) translocations without prior knowledge of the fusion partner Therefore, the TLA multiplex panel is suited as a first tier screening tool in acute leukemia. A prospective study, comparing the diagnostic yield of the TLA panel with current tests, can establish whether the TLA panel is applicable as a routine procedure.

ALTERATIONS IN NECROPTOSIS PATHWAY AFFECT PROGNOSIS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

S. Lo Monaco[1,*], G. Marconi[1], M.C. Fontana[1], C. Papayannidis[1], E. Ottaviani[1], E. Franchini[1], A. Ferrari[1], A. Padella[1], G. Simonetti[1], S. Paolini[1], G. Martinelli[1]
[1]University of Bologna, Bologna, Italy

Background: Necroptosis is a type of necrotic cell death involving several genes transcription and activation of molecular mechanisms as death receptors, interferon, toll-like receptors, intracellular RNA and DNA sensors. The process is leading by the family of receptor-interacting protein kinase (*RIPK3*, *RIPK2*, *RIPK1*) and the *MLKL* substrate. Losses of *RIPK3* or *MLKL*, as well as deficiency in apoptosis, could allow tumor cells to escape the immune-mediated cells death (ICD).
Aims: We want to investigate the role of necroptosis deficiency in correlation with chemotherapy resistance and its impact as prognostic factor in AML.

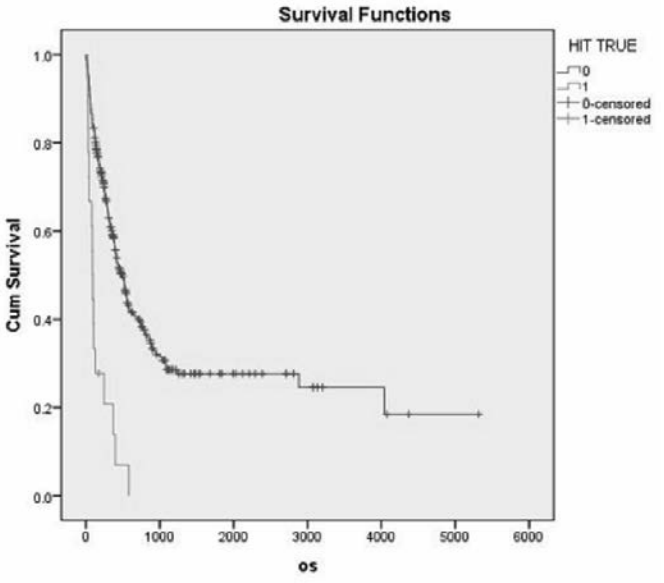

Figure 1.

Methods: We performed SNP Arrays (Cytoscan HD and SNP 6.0, Affymetrix) on a cohort of 300 non-M3 AML patients at diagnosis and we analyzed the Overall Survival (OS) of our patients with deficiency on necroptosis pathways. Survival was analyzed with Kaplan-Mayer method and Log-Rank test. We further analyze the relevance of different prognostic factors by the use of COX-Hazard Ratio statistical analysis.
Results: We found that 18 patients presented a loss of *RIPK1* or *MLKL* (nobody presented losses in *RIPK3/RIPK2*) and 13/18 patients were older than 65 years old. The Overall Survival (OS) of patients with alterations in these genes is significantly lower than control group, with a median OS of 3 *vs* 6 month respectively (p<.0.001). With Fisher Exact Test we further demonstrate that copy number loss of *RIPK1* or *MLKL* are associate to loss of *TP53* or *FANCA* genes, complex karyotype and advanced age. COX-Hazard Ratio model with *RIMK1* or *MLKL* loss, *BRCA1* loss, *TP53* mutation, *FANCA* loss, secondary disease and diagnosis karyotype considered as categorical variable show that necroptosis deficiency (HR 1.98, CI 95% 1.04-3.78) *TP53* mutation, and secondary AML are independent negative prognostic factors in an optimal model.
Summary/Conclusions: Our study shows that losses in necroptosis pathways are an uncommon alteration in AML, prevalent in old population. Moreover, we hypothesize that the loss of genes involved in necroptosis could be a real mechanism of tumor immune-escape and could be a rational to select patients that high probability to be resistant at chemotherapy promoting ICD mechanism.

NGS ANALYSIS AND IMPACT OF VARIANT ALLELIC FREQUENCY AT RELAPSE AND REFRACTORINESS STATUS IN AML PATIENTS

E. Onecha De La Fuente[1,2,*], I. Rapado[1,2], M. Llops[3], Y. Ruiz-Heredia[1,2], T. Cedena[1,2], E. Barragan[3,4], M. Gallardo[1,2], J. Martinez Lopez[1,2], R. Ayala[1,2]
[1]Hematologia traslacional, Hospital 12 de Octubre, [2]Haematological Malignancies Clinical Research Unit, CNIO, Madrid, [3]Instituto de Investigación Sanitaria La Fe, [4]Clinical Pathology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain

Background: A high number of patients with acute myeloid leukemia (AML) present resistance at treatment, which is associated with clonal persistence or evolution. The generation of high-depth sequencing data allowed to quantify variant allelic frequencies (VAF) and permitting estimation of the size of tumor clonal populations in each AML sample, and to perform an estimation of clonal evolution at relapse or refractory case according at diagnostic.
Aims: To evaluate the predictive impact of the fluctuation Variant Allelic Frequency in resistance to treatment cases in AML.

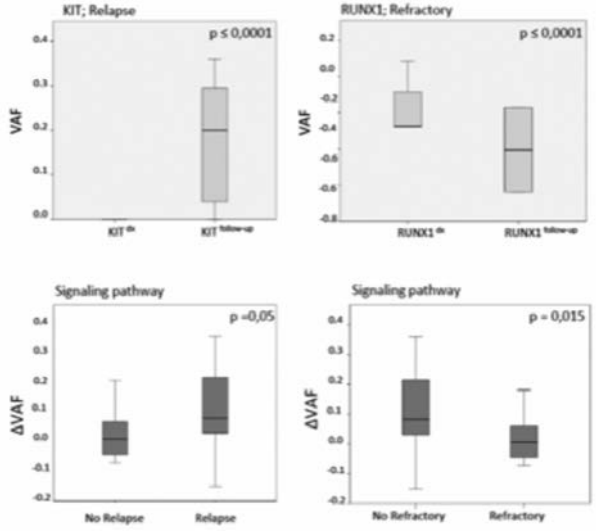

Figure 1. On top, representation of VAF at follow-up respect to the diagnosis in the most significant gene at relapse (KIT) and refractory (RUNX1). On bottom, representation of the fluctuation of VAF in patients with mutated gene in signaling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) related to resistence to treatment event.

Figure 1.

Methods: We performed a custom-targeted sequencing panel of 32 genes (all coding regions) implicated in leukemia prognosis, including ASXL1, CBL, DNMT3A, EPOR, ETV6, EZH2, FLT3, HRAS, IDH1, IDH2, JAK2, KDM6A, KIT, KRAS, LNK, MLL, MPL, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF35, VHL, ZRSR2 and CALR, by *Ion Torrent Proton System-Thermo Fisher. P*rimary tumor-refractory (n=8) and primaty tumor-relapsed (n=17) samples pairs from 25 AML patients treated according *PETHEMA AML* clinical protocols were sequenced; in addition FLT3-ITD was detected by GENSCAN and NPM1 mutation was detected by PCR. We analyse the evolution of level of VAF, to measure the prevalence of somatic mutations between diagnosis and resistance status (relapse or refractory).
Results: Mutations in signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) and GTPases pathway (KRAS, NRAS, HRAS) present significant ΔVAFs increases in relapse samples, p=0.05 and p=0.039 respectively. See figure 1. Furthermore, mutations in IDH2, JAK2 or KRAS show ΔVAF trend increases. Also, mutations in signalling pathway shows significant ΔVAF decrease in primary refractory samples, p=0.015; mutations in JAK2, KMT2A or SF3A1 shows ΔVAF trend decreases. Regarding to mutational profile we found significant differences in the VAF evolution in relapse samples, with VAF increment in IDH1 (p=0.031), KDM6A (p=0.018), KIT (p=0.000), PRPF40B (p=0.019), SF1 (p=0.033) and SF3A1 (p=0.044). Also, we found significant differences in the VAF evolution of primary refractory samples, reduced in KMT2A (p=0.016), RUNX1 (p=0.000) and the methylation pathway (DNMT3A, EZH2, KMD6A, MLL, TET2, IDH1 and IDH2; p=0.043). Mutations in TET2, U2AF1 or SF3A1 show VAF trend decreases. No correlation was found between VAF and% blasts, nor did VAF fluctuation with blasts fluctuation.
Summary/Conclusions: These results show VAF increases of specific mutations as KIT correlates with relapse status. However, in this cohort new specific mutations were not found neither VAF increases, even the opposite being as VAF decreases of specific mutations as RUNX1 correlates with primary refractoriness status. Furthermore, the variable frequency signalling pathway (EPOR, FLT3, JAK2, KIT, LNK or/and MPL) play a critical role in resistance status, increasing variant allelic frequencies of mutations in relapse and decreasing in refractoriness.

PRECLINICAL EVIDENCE THAT TRAMETINIB ENHANCES THE RESPONSE TO TYROSINE KINASE INHIBITORS IN ACUTE MYELOID LEUKEMIA

M.L. Morales[1,*], M. Linares[1], A. Arenas[1], I. Zagorac[2], R. Ayala[2], N. Castro[1], I. Rapado[1], M. Quintela-Fandino[2], J. Martinez-Lopez[1]
[1]Servicio de Hematologia, Hospital Universitario 12 de Octubre, [2]Unidad de Proteomica, Centro Nacional de Investigaciones Oncologicas, Madrid, Spain

Background: Acute Myeloid Leukemia (AML) is the most common type of acute leukemia in adults and the second in children in whom overall survival is less than 35% and 60% respectively. Activating mutations of FLT3 are now recognized as the most common molecular abnormality in this disease, and the poor prognosis of patients harboring these mutations renders FLT3 an obvious therapeutic target. Although different tyrosine kinase inhibitors (TKI) have been used for this purpose, their ability to extend progression-free and overall survival is limited by drug resistance. This strategy could be improved by rationally combining TKIs with other agents. In this work, we have explored bone marrow samples from a FLT3-AML patient before and after TKI treatment by phosphoproteomics and observed enhanced activity of Ras-Raf-MEK-ERK1/2 pathway as a possible mechanism for TKI resistance.
Aims: To validate the role of ERK1/2 during TKI resistance *in vitro* and *ex vivo* and to search suitable combinations that allow overcome/avoid resistances in preclinical models of the disease.
Methods: Resistance mechanisms were studied *in vitro* in MOLM13 ($FLT3^{WT/ITD}$) after generating resistance by two different methods: by subculturing with increasing doses of sorafenib or by treating them with high doses of sorafenib, and recollecting alive proliferative (resistant) cells after CFDA and Anexinn labeling. Phosphoproteomic analyses were carried out by LC-MSMS after IMAC enrichment or by western blot techniques. Drug sensitivity assays with trametinib (MEK inhibitor) and three TKIs (sorafenib, pazopanib, midostaurin) were read after 48 hours or 72 hours of treatment *in vitro* or *ex vivo* respectively. The efficacy of the combinational treatments was characterized by the cell viability assay using WST8, and analyzed with Graphpad Prism software. Synergy effects were measured with Calcusyn software.

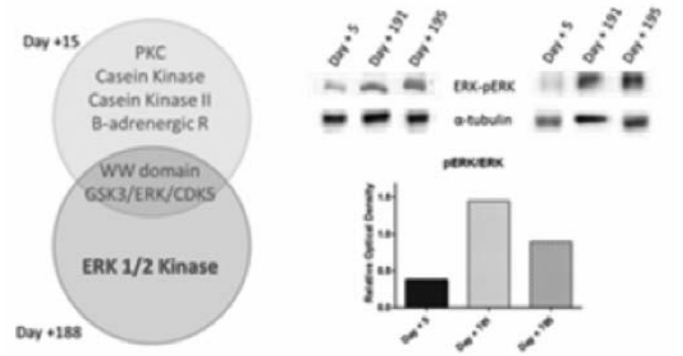

Figure 1.

Results: As it is presented in figure 1, ERK1/2 pathway was more activated after TKI treatment in the FLT3-AML patient during sorafenib-resistance development. The same fact was confirmed in MOLM13 sorafenib-resistant culture and in living proliferative cells recollected after sorafenib treatment. Different doses of trametinib, sorafenib, pazopanib and midostaurin in monotherapy were tested in MOLM13 cell line determining their IC50 values. Sinergy effects of combining trametinib with the three TKIs were analyzed with Calcusyn software and normalized isobolograms were represented. All combinations showed CI values less than 0.5 (Ci<0.5). The inhibition levels of four pathways (PI3K, STAT5, ERK1/2 and MAPK14) implicated in TKIs resistance were studied by western blot and the combination of midostaurin plus trametinib was the only one that inhibited all of them. Trametinib efficacy in the MOLM13 sorafenib-resistant culture was evaluated and confirmed that remained effective. Trametinib plus midostaurin combination was tested in OCI AML-3 cell line ($FLT3^{WT/WT}$) showing high efficacy and strong synergy (CI<0.5) too. Finally, we have assayed these drugs *ex vivo* in three AML samples showing the same effectiveness as *in vitro*, with IC50 values ranging from 0.2μM to 0.9 μM for midostaurin and 3 nM to 29 nM for trametinib and Ci values less than 0.5.
Summary/Conclusions: In conclusion, we provide preclinical evidence that combining a TKI, especially midostaurin, with a MEKI, such as trametinib, is a rational and efficacious treatment regimen for AML. As trametinib has previously shown good results when combined with pazopanib in clinical trials for other kind of tumors, we expect similar results in AML.

E901

IDENTIFICATION OF NOVEL THERAPEUTIC DRUGS IN DISTINCT PEDIATRIC AML SUBTYPES BY TARGETING EPIGENETIC REGULATORS

C. Wiggers[1,2,*], D. Lelieveld[3], D. Egan[3], M. Bartels[1]
[1]Pediatrics, University Medical Center Utrecht, [2]Hubrecht Institute, [3]Cell Screening Core, Cell Biology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Treatment protocols for pediatric acute myeloid leukemia (AML) are chemotherapy-based, including high-dose cytarabine. While >90% of patients reach clinical remission, there is still a high relapse rate of ~30%, with overall survival rates of 60-70%. Therefore, better risk-classification at diagnosis and alternative treatment strategies are warranted. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including AML. Epigenetic processes are required for hematopoiesis and epigenetic regulators are frequently translocated (MLL) or mutated (EZH2) in AML. Following this, deregulated epigenetic pathways could be used for targeted therapy and provide an alternative approach to improve pediatric AML therapy.
Aims: To identify new therapeutic drugs in pediatric AML by using an 80-compound screen containing inhibitors of epigenetic regulators, including histone writers (which deposit post-translational modifications (PTMs) on histones), readers (binding of PTMs) and erasers (removal of PTMs).
Methods: Cell lines used in this study are THP-1 (t(9;11)), Kasumi-1 (t(8;21)) and CMK (Down's syndrome with GATA1 mutation), reflecting distinct pediatric AML entities and a differential response to treatment with cytarabine. Cells were treated for 72hrs followed by analysis of cell viability and apoptosis based on Hoechst, Draq7 and Calcein Green staining. The effect of three candidate compounds were further investigated in triplicates at several concentrations for their effect on cell viability (Annexin V/PI staining), cell cycle, morphology, and apoptosis in the cell lines, normal myeloid precursor cells derived from cord blood, and pediatric AML patient cells representing distinct AML subtypes.
Results: From the 80 epigenetic compounds tested in THP-1, Kasumi-1 and CMK cells, we observed significant effects following treatment with the HDAC 4/5 inhibitor LMK235, the pan-HDAC inhibitor NSC3852, and the pan-bromodomain inhibitor Bromosporine. Dose-response curves showed differential cytotoxicity of the compounds and suggested LMK235 as most effective. Cell proliferation was inhibited by LMK235 at an IC50 of 0.1uM, 0.13uM and 0.425uM in Kasumi-1, CMK and THP-1, resp. While inhibition by LMK235 resulted in an immediate response of apoptosis, Bromosporine-treated cells retained in G1 before undergoing apoptosis and, interestingly, NSC3852 treatment resulted in an increase of cells in S-phase and G2/M. Among the differential effects of the compounds in the cell lines, we also observed differences in sensitivity. In line with previous studies, THP-1 cells were more resistant, illustrated by a 10-fold increase in concentration required for NSC3852-induced apoptosis. Interestingly, upon treatment with Bromosporine, Kasumi-1 and CMK cells showed a similar response, while Kasumi-1 cells were significantly more sensitive to NSC3852-induced effects. These data are currently validated in pediatric AML patient cells.
Summary/Conclusions: Treatment of three distinct pediatric AML cell lines with the epigenetic compounds LMK235, NSC3852 and Bromosporine resulted in cell line-specific effects, regarding compound sensitivity, and compound specific effects, including cell cycle regulation and induction of apoptosis. Our data suggests a potential role for epigenetic compounds, with specificity for molecular subtypes, in the treatment of clinically and biologically distinct pediatric AML subtypes.

ALVOCIDIB SYNERGIZES WITH CYTARABINE AND DAUNORUBICIN (7+3) IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

W. Kim[1], H. Haws[1], R. Mangelson[1], P. Peterson[1], C. Whatcott[1,*], A. Siddiqui-Jain[1], S. Weitman[1], D. Bearss[1], S. Warner[1]
[1]Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: Although survival of patients with acute myeloid leukemia (AML) has increased in the years 1975-2011, the 5-year, overall survival of patients with AML remains unacceptably low at an estimated 26% (2011). '7+3' treatment (cytarabine 100-200mg/m^2 + anthracycline [daunorubicin 60-90mg/m^2/day or idarubicin 12mg/m^2/day]) remains the standard induction therapy in AML patients, and has persisted largely unchanged for more than 30 years. There is a significant unmet clinical need for improved therapeutic options in patients with AML. Alvocidib is a CDK9 inhibitor currently in development for the treatment of patients with AML. Alvocidib has previously been studied as part of the ACM regimen, a combination regimen incorporating the time-sequential (TST) administration of alvocidib, cytarabine, and mitoxantrone, in multiple Phase 1 and 2 clinical trials. The ACM regimen has achieved significant improvements in complete response (CR) rates *versus* 7+3 in previously untreated intermediate and high-risk AML patients. The rationale for time-sequential administration of the ACM regimen was developed with an incomplete understanding of alvocidib's mechanism of action. TST was based on the expectation that alvocidib would synchronize cells, capitalizing on the S-phase specific activity of cytarabine in the combination. However, rather than cell-cycle inhibition, alvocidib potently induces apoptosis by inhibiting the expression of key anti-apoptotic proteins via CDK9/RNA polymerase II, including MCL-1. With this understanding, we reasoned that alvocidib would also enhance the activity of the 7+3 regimen.
Aims: These studies sought to interrogate the preclinical activity of alvocidib in the context of the 7+3 regimen in models for AML.
Methods: CellTiter-Glo and Caspase-Glo was used for all cell viability and apoptosis assays interrogating alvocidib and 7+3 activity in cell lines, following manufacturer's protocol. We used RT-PCR to measure mRNA expression of MCL-1 and other markers in response to drug treatment. Protein levels were interrogated using standard immunoblotting techniques. To determine the efficacy of an alvocidib/7+3 combination on tumor growth *in vivo*, we performed a MV4-11 xenograft mouse study.
Results: Single agent IC_{50} values of alvocidib, cytarabine, and daunorubicin range in AML cell lines from 2.2 nM to as high as 567 nM in viability assays. In apoptosis (Caspase-Glo) assays, however, we observed modest induction with single agent cytarabine, and good induction with single agent daunorubicin or alvocidib. In the combination, however, we observed very strong synergy with more than two-fold enhanced induction of apoptosis in some treatment groups. As has been previously described, we report here too that alvocidib treatment reduced the expression of MCL-1 protein and mRNA in a time and concentration-dependent fashion in AML cells. We observed this in the 7+3 treatment context as well. In an MV4-11 xenograft model, we observed 21.1 and 48.5% tumor growth inhibition (%TGI) following single agent treatment of daunorubicin or cytarabine, respectively. 1.25mg/kg alvocidib yielded 60.0%TGI. The combination of alvocidib, cytarabine, and daunorubicin, however, resulted in tumor regression, yielding a 116.2%TGI.
Summary/Conclusions: Though multiple clinical studies have demonstrated the increased efficacy of the ACM regimen over 7+3 in AML, these studies cannot correctly capture the clinical contribution of alvocidib alone as they do not offer a direct comparison. The current study attempted to interrogate the contribution of alvocidib to the 7+3 induction regimen, in preclinical models. These results provide a clear rationale for a clinical study directly comparing the triple combination to 7+3 alone. Taken together, our results suggest that a combination of alvocidib, cytarabine, and daunorubicin might be a potential clinical regimen in treating frontline AML, offering patients additional treatment options in treating their disease.

E903

COMBINATION OF INTERFERON-ALPHA AND VALPROIC ACID IN ACUTE MYELOID LEUKEMIA CELLS IN VITRO AND IN VIVO

R.B. Forthun[1], A. Sulen[1], G. Sjøholt[2], Ø. Bruserud[3,4], E. Mc Cormack [1], B.T. Gjertsen[1,3,*]
[1]Centre for Cancer Biomarkers (CCBIO), University of Bergen, [2]Department of Biomedical Laboratory Sciences and Chemical Engineering, Bergen University College, [3]Department of Internal Medicine, Haematology Section, Haukeland University Hospital, [4]Department of Clinical Science, Leukemia Research Group, University of Bergen, Bergen, Norway

Background: Interferon alpha (IFNα) monotherapy is effective in selected myeloid neoplasias and is proposed to act through mechanisms that may be additive to the action of valproic acid (VPA), a histone deacetylase (HDAC) class I and IIA inhibitor with effect in approximately 20% of acute myeloid leukemia (AML) patients. Both drugs are found to have direct anti-cancer effects targeting apoptosis, differentiation and proliferation, as well as indirect effects targeting the immune system.
Aims: As several IFNα formulations are commercially available, we wished to explore the differences between two such drugs, recombinant IFNα-2b and human IFNα-Le, in relevance to AML treatment.
Methods: Flow cytometry and Hoechst staining was used to investigate apoptotic potential of the IFNα therapeutics, whilst phospho-flow cytometry and difference gel electrophoresis in combination with mass spectrometry unraveled IFNα signaling pathways. For *in vivo* effectivity analyses two orthotopic rodent models were implanted with leukemic cells and treated with VPA, IFNα-Le or both drugs.
Results: To investigate the anti-leukemic effects of IFNα we combined the two therapeutics with VPA *in vitro* using the human MOLM-13 cell line (wild type for FLT3 ITD and TP53). Results showed that IFNα-Le was more efficient compared to IFNα-2b in inducing apoptosis, whilst both were synergistic in combination with VPA. Investigating IFNα signaling pathways using phospho-specific flow cytometry we found IFNα-2b and IFNα-Le to have an identical stimulation profile in MOLM-13 cells, except from p-STAT6 Y641 that was higher expressed by IFNα-2b. The phospho-proteome was further explored using difference gel electrophoresis (DIGE) and mass spectrometric analyses to find a potential explanation to the difference in apoptosis-inducing effects between the two drugs. Here we found protein folding (LCP1, HSPA8, TCP1, CCT6A), cell stress (AKR1B1, HSP90AB1) and cell death (PKM2, PARK7, HSPB1, HSPA5, ANXA5, PRDX2) to be differently regulated between IFNα-2b and IFNα-Le, and also identified the presence of a dose-dependent effect on protein expression by IFNα-2b and IFNα-Le. Further, we investigated the potential synergistic anti-leukemic effects of VPA and IFNα-Le *in vivo* using a MOLM-13^{Luc+}immunodeficient NOD/Scid IL2 g$^{-/-}$ orthotopic xenograft mouse model, and the

immunocompetent brown Norwegian myeloid leukemia (BNML) syngeneic rat model. VPA mono-treatment increased survival from a median of 34 days to 38 days in the MOLM-13^{Luc+}mouse model, and from 21 days to 50 days in the BNML rat model. Additionally, the IFNα-Le ($0.8x10^6$ IU/kg) and VPA (400mg/kg) combination treatment indicated a tendency to increased survival in the BNML model. However, IFNα-Le monotherapy ($1x10^6$ IU/kg) decreased survival in the MOLM-13^{Luc+} model.

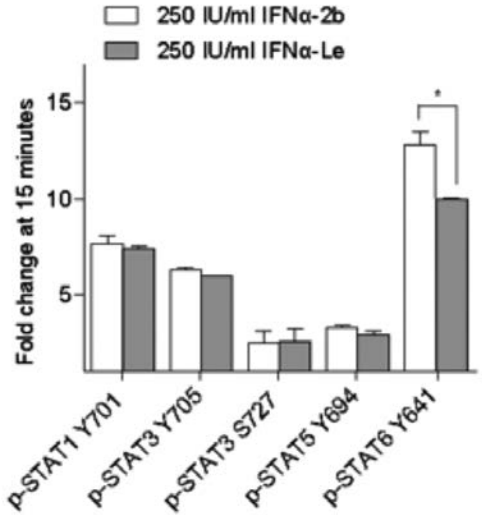

Figure 1.

Summary/Conclusions: IFNα does not add beneficial effects to VPA treatment in the two *in vivo* orthotopic models tested, possibly due to immune constitution and tumor load.

E904

KEVETRIN: PRECLINICAL STUDY OF A NEW COMPOUND IN ACUTE MYELOID LEUKEMIA

R. Napolitano[1], S. De Matteis[1,*], S. Carloni[1], G. Simonetti[2], G. Musuraca[3], A. Lucchesi[3], D. Calistri[1], A. Cuneo[4], K. Menon[5], G. Martinelli[2]
[1]Bioscience Laboratory, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, [2]Department of Hematology and Oncological Sciences, L. and A. Seragnoli, Bologna, [3]Hematology Unit, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, [4]Department of Medical Sciences, University of Ferrara-Arcispedale Sant'Anna, Ferrara, Italy, [5]Cellceutix Corporation, Beverly, United States

Background: Acute Myeloid Leukemia (AML) is a heterogeneous disorder defined by clonal expansion of immature myeloid cells that infiltrate bone marrow and other tissues. AML therapeutic strategies remain unchanged since 1970 and the majority of patients often eventually relapse and die due to disease progression. Tumor protein p53 transcription factor is a key regulator of several cellular pathways, such as DNA repair, cell cycle, apoptosis and angiogenesis. It is mutated in 8-14% of AML cases and its mutations are commonly associated with a complex karyotype. Kevetrin is a new molecule compound, proposed by Cellceutix, with the ability to target both wild type and mutant p53 tumors.
Aims: The aim of this project is to explore cellular and molecular alterations induced by Kevetrin, focusing on its role in the p53 pathway.
Methods: Kevetrin was kindly provided by Cellceutix, dissolved and stored at 4°C in sterile water in a 600 µg/ml stock solution, and diluted in medium immediately before use [concentration range in use 15-60µg/ml]. Cell lines, MOLM-13 and KASUMI-1, were cultured in RPMI 1640 supplemented with 20% heat inactivated fetal bovine serum, 2mM L-glutamine, 100 U/ml penicillin and 100 µg/ml streptomycin. After 24 and 48 h of treatment MTS, Annexin-V, TUNEL, JC-1 and Active Caspase-3 assays were performed according to manufacturer's instructions. Proteins were separated by polyacrylamide gel electrophoresis and transferred to 0.2 µm polyvinylidene fluoride membranes. Quantitative analysis was performed with Quantity One software. Statistical analysis was carried out using the paired and unpaired two-tailed Student's t tests. p values <0.05 were considered as significant.
Results: Our data indicate that Kevetrin exposure induces cell growth arrest, a great drop of mitochondrial membrane potential and a remarkable increment of Caspase-3 cleaved form, features that contribute to apoptotic cell death in the two cell lines. Cellular changes can be associated with a dose and time-dependent effect in the *TP53* mutated cell line (KASUMI-1) but not in the wild type one (MOLM-13), in which we can observe an activity only after 48 h at the higher concentration. Regarding molecular alterations in KASUMI-1 we found a great p53 down-regulation, probably due to Hsp90 reduction, resulting in a less marked formation of the Hsp90-p53 oncogenic complex. We also found a down-regulated p53 active form (Ser15), a reduced expression of p53 targets, p21 and PUMA, and a down-regulation of SIRT-3, that cannot exert its inhibitory activity on p53. The MOLM-13 cell line showed a great p53 reduction, probably related to SIRT-3 up-regulation and Hsp90 down-regulation. Regarding p53 active form, we noticed slight variations in protein expression, suggesting a physiological response of the protein to cellular damage. In accordance with p53 activity, we observed a great up-regulation of p21, probably associated with a drug resistance mechanism; in contrast, PUMA protein was highly down-regulated, suggesting a p53-independent mechanism of action or a feedback regulation of the apoptotic process, after Caspase-3 activation (Figure 1.). In order to better understand drug's mechanism of action we are performing gene expression profiling after 48h of treatment with Kevetrin 60µg/ml.

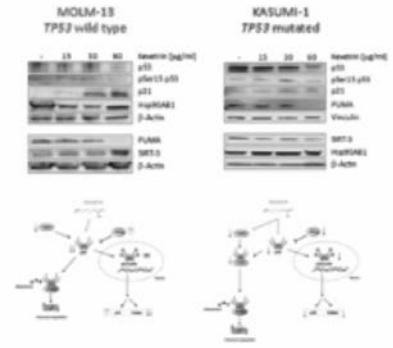

Figure 1.

Summary/Conclusions: Our results suggest Kevetrin is a promising new drug in AML patients treatment, both in wild type and, even more, in *TP53* mutated tumors, through different molecular mechanisms, giving more therapeutic alternatives in the treatment of this disease.

E905

CLEARANCE OF 'DRIVER-COSMIC' MUTATIONS POST CR1 WITH PERSISTING RUNX1_L56S IS UNLIKELY TO CONTRIBUTE TOWARDS DISEASE PROGRESSION IN AML

L. Rai[1,*], T. Boneva[2], D. Brazma[2], R. Dunn[2], C. Grace[2], E. Nacheva[2,3]
[1]Onco-Cytogenomics, [2]OncoGenomics, HSL Analytics LLP, [3]Cancer Research Institute, UCL, LONDON, United Kingdom

Background: Clinical significance of gene variants in AML is well established (Papaemmanuil E *et al,* NEJM 2016) and is increasingly being implemented into routine diagnostic algorithms. Although 80% of patients achieve morphological remission after induction chemotherapy, long-term relapse free survival is a meagre 50% (Walter RB *et al*, JCO 2010. Monitoring of disease kinetics, is therefore, very critical.
Aims: To study the kinetics of gene variants post-induction chemotherapy in AML patients.
Methods: 130 follow-up samples from 45 *de novo* AML patients [median age-60 yr & median FU period- 18.6 mo] were screened for gene variants using TruSight Myeloid panel (Illumina, CA, USA) covering 54 genes with relevance in myeloid diseases. Gene variants at Variant allele frequency (VAF) of ≥10% at diagnosis and VAF of ≥1.5% during follow-up; both with target coverage of ≥300 reads were considered. Bone marrow (BM) or peripheral blood (PB) was obtained at presentation (BM:44; PB:1) and follow-up (BM-130). Gene variants in 95 samples from 40 MDS patients were also evaluated for progression to secondary AML. Public databases-Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (>2%) were used to classify gene variants as either Drivers (D), variants of unknown significance (VUS) and germline polymorphisms (SNP). P-value was generated with 2-tailed Fisher Exact (GraphPad Software, Inc, USA).
Results: Of 45 AML patients 19 achieved complete morphological remission (CR), 21 had a relapse and 5 had refractory disease with a median of 4 mutations/patient in each subgroup. Driver mutation was identified in 38 patients; 82% of who had persistence until clinical end-point. While 17 of 18 relapse patients retained a driver only 9 of 15 patients in remission retained it (Table 1). 8 of the 9 patients had a 'driver with COSMIC and SNP' (D-C/S) reference that persisted, while all 'driver with COSMIC only' (D-C) disappeared post-induction. This suggests that drivers with both COSMIC and SNP reference may not always contribute towards disease progression. We also found that D-C mutations persist in 85.7% of relapse pat.ients compared to only 11% of patients in remission (P-value: 0.001). Additionally, D-C mutations were retained in all 13 relapse patients with intermediate risk cytogenetics while complete clearance was observed in all 6 patients who were in sustained remission (P-value: 0.001). Further investigation of genes with D-C/S mutation in the remission cohort (8x) revealed that 4 patients had persistent DNMT3A-25457242, 1 had DNMT3A-25457243, 2 had RUNX1-36259324/L56S and 1 had CBL-119149011. As DNMT3A mutations are considered to occur in pre-leukemic

stem cells contributing to clonal haematopoiesis (Askush *et al*, Nature 2014; Genovese *et al*, NEJM 2014); this led us to study the distribution of RUNX1 gene variants in an additional 119 AML diagnostic samples. 34 patients (21%) harboured RUNX1 mutation, of which 5 had RUNX1_L56S that were often associated with D-C mutations (4 of 5 cases). Finally, we evaluated kinetics of D-C in 40 MDS cases of which 34 had chronic MDS and 6 had secondary AML (sAML). No significant difference was observed in the number of patients with persistent D-C mutation in the 2 subgroups (chronic MDS: 16 of 19 (84.2%); sAML: 5 of 5 (100%); P-value: 1.000).

Table 1.

AML Cohort (Total no. of patients: 45)				
Clinical Outcome		Morphological remission	AML relapse	Refractory disease
No. of patients in each clinical outcome category		19	21	5
Mean Age (Range) (in years)		55.8 (32-71)	57.3 (30-77)	63.8 (43-82)
No. of patients ≤60 years		10 of 19	10 of 21	2 of 5
Time to clinical end-point(Range) (in months)		5.2 (3-15)	17.8 (3-66)	4 (3.7-22.7)
Cytogenetics	Good	1	1	2
	Intermediate	12	16	0
	Poor	3	2	3
	Missing data	3	2	0
Median no. of mutations per patient at presentation		4	4	4.4
No. of patients with D-mutation at presentation		15	18	5
No. of patients with Dx D-mutation that was retained until clinical end-point		9 of 15*** (60%)	17 of 18 (94%)	5 of 5 (100%)
No. of patients who retained Dx D-mutation and acquired new D-mutations at clinical end-point		0	8 of 17	0
No. of patients who lost Dx D-mutation and/or acquired new D-mutations at clinical end-point		6 of 15 (40%)*	1 of 18** (6%)	0
No. of patients with Dx D-mutation that dissappeared and then reappeared at clinical end-		0	5 of 17	0
No. of patients without D-mutation at presentation		4	3	0
Of these how many acquired a D-mutation at clinical end-p		0 of 4	0 of 3	0
No. of patients with 'D-C' mutation persistent until clinical end-		1 of 9 (11%)^^	12 of 14 (85.7%)	2 of 3 (66.7%)
No. of patients with intermediate risk cytogenetics and D-mutation at Diagnosis		10 of 13	14 of 16	1 of 1
No. of patients with intermediate risk cytogenetics and persistent D-mutation at clinical end-point		6 of 10 (60%)	13 of 14 (93%)	1 of 1 (100%)
No. of patients with intermediate risk cytogenetics and persistent 'D-C' mutation		0 of 6 (0%)	13 of 13 (100%)	1 of 1(100%)

Table 1: Characteristics of patients and their gene variants in the three clinical subgroups of AML. SNP: Single Nucleotide Polymorphism; Dx: Diagnostic; D-mutation: driver mutation; D-C mutation: driver with COSMIC only

Summary/Conclusions: Clearance of 'Driver-COSMIC only' mutations while RUNX1_L56S persists is unlikely to contribute towards disease progression in AML.

Acute myeloid leukemia - Clinical

E906

PROGNOSTIC SIGNIFICANCE OF FLT3 STATUS, CYTOGENETIC, ECOG AND 50% BLAST DECREASE IN PRIMARY REFRACTORY OR EARLY RELAPSED AML PATIENTS BEFORE SALVAGE THERAPY

P. Sesques[1], S. Bertoli[2], M. El-Hamri[1], S. Ducastelle[1], G. Salles[1], C. Recher[2], X. Thomas[1], E. Paubelle[1,*]
1hematology, Chu Lyon Sud, Pierre Benite, 2hematology, Oncopole Toulouse, Toulouse, France

Background: Prognosis of relapsed/refractory acute myeloid leukemia (R/R AML) is unfavorable with a long term overall survival around 10%. Thus, management of R/R AML represents one of the most difficult challenges. Because allogeneic-Hematopoietic Stem Cell Transplantation (allogeneic-HSCT) is considered as the best treatment for this category of patients, to determining which patient will benefit from this cumbersome strategy is a crucial issue. A better understanding of the mutational status, cytogenetic, histological and clinical findings of early R/R AML patients and their outcomes could help treatment decisions, particularly for those who allogeneic-HSCT is considered as the best therapeutic option.
Aims: The objective of this study is to determine prognostic factors and develop a prognostic score using usual mutational status, cytogenetic, histological and simple clinical variables in R/R AML patients before salvage treatments.
Methods: In this retrospective study in two hematological departments (Hospices Civils de Lyon and CHU of Toulouse), we evaluated clinical, biological, histological, cytogenetic and current mutational status of early R/R non APL AML patient between age from 18 to 70 years. Univariate and multivariate analysis were performed and we developed a prognostic score based on the independent prognostic parameters from Cox model.
Results: From January 2009 to May 2016, 58 patients presenting early relapse and primary refractory AML were analyzed. Overall Survival (OS) and Progression Free Survival (PFS) median were 9 and 2 months respectively. In univariate analysis, cytogenetic findings (unfavorable groups), unfavorable ECOG (>2), FLT3 positive status and <50% blast decrease (between induction and R/R assessment) independently predicted poor OS and were identified as significant prognostic parameters of OS (p=.037, p=.0084, p=.0452, p=.0071 respectively). In multivariate analysis, these last four criteria confirmed their worst prognostic impacts (p=.015, p=.017, p=.026, p=.015 respectively) and were used to create a five groups prognostic score. Better OS were statistically observed for patient with score 0 or 1 compared to 2, 3 or 4 (2-years OS 48% and 11% respectively, p= 0.0104) using a log-rank regression. When data were censored to allogeneic HSCT, the scoring system revealed a relevant difference with favorable OS for those with a score 0-1 compared to score 2-3-4 (2-years OS 64% and Not Reached respectively, p=.001) (Figure 3).

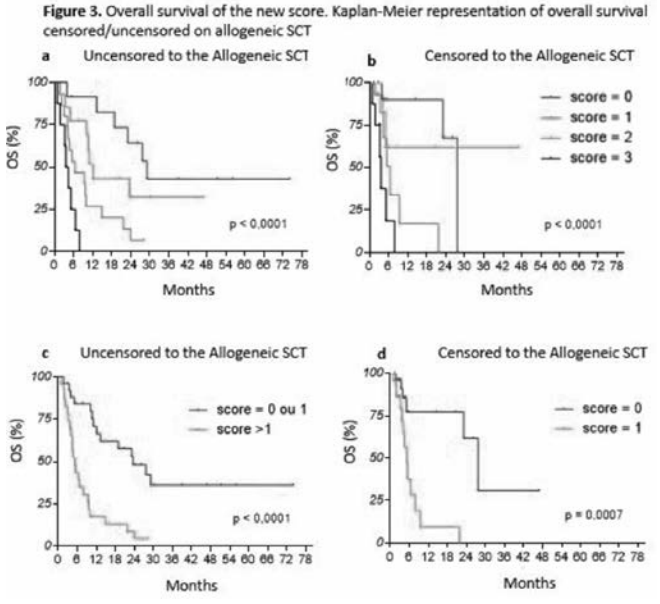

Figure 1.

Summary/Conclusions: Our prognostic score based on simple and usual data: FLT3 status, cytogenetic, ECOG and percentage blast decrease found distinct groups with statistically different outcomes. Basically, the higher is the score, the worst is the OS. This new score is a valuable, simple and useful score for the therapeutic salvage management of AML patients presenting early relapse and primary refractory.

E907

PRELIMINARY RESULTS FROM A PHASE 1 STUDY EXAMINING THE NOVEL BCL-2 INHIBITOR S55746/BCL201 AS SINGLE AGENT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH RISK MYELODYSPLASTIC SYNDROME

A. Wei[1,*], A. Bajel[2], N. Boissel[3], I. Kloos[4], C. Delifer[4], S. Banquet[4], X. Thomas[5], N. Vey[6]

[1]Department of Clinical Haematology, The Alfred Hospital and Monash University, [2]Department of Haematology & Bone Marrow Transplantation, The Royal Melbourne Hospital, Melbourne, Australia, [3]Department of Hematology, Hôpital Saint Louis, Paris, [4]Servier, Suresnes, [5]Department of Hematology, Centre Hospitalier Lyon Sud, Lyon, [6]Department of Hematology, Institut Paoli-Calmettes, Marseille, France

Background: Novel and effective therapeutic options for patients (pts) with advanced acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) are limited. Targeting the prosurvival molecule BCL-2 is clinically efficacious in various hematological malignancies. S55746/BCL201 is a novel, selective and potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models.
Aims: To evaluate the safety, recommended phase 2 dose (RP2D), pharmacokinetic (PK), pharmacodynamic (PD) and preliminary activity of S55746/BCL201 in patients with AML [relapsed/refractory (R/R) or ≥65 years unfit for intensive chemotherapy (IC)], or MDS failing prior therapies.
Methods: A phase I study (EUDRACT 2014-002559-24, NCT02920541) is underway to investigate S55746/BCL201 as a single agent in 5 European and Australian centers. S55746/BCL201 was initially administered in fasting conditions, once daily (21-day cycles), until disease progression, unacceptable toxicity, or investigator's or patient's decision. Pts giving informed consent received S55746/BCL201 at escalating dose levels according to a modified continual reassessment method for dose allocation.
Results: As of 23 February 2017, 34 pts have received S55746/BCL201 at doses ranging from 100 to 1300mg/day (median time on treatment: 43 days, range 1 to >374); 28 pts were R/R AML, 2 pts were elderly AML unfit for IC, and 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 3 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-I in 20%, and intermediate-II in 17%. Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. Most common (≥20% of pts) non-hematological adverse events (AEs), all grades, included diarrhea (27%), hypokalemia (27%), nausea (21%), and vomiting (21%). The most frequent grade ≥3 AEs were hematological [anemia (35%), thrombocytopenia (32%), febrile neutropenia (21%), and neutropenia (18%)], hypokalemia (18%), and sepsis (15%). Of 12 pts (38%) with AEs possibly related to study drug, the most frequent were diarrhea (3 pts), muscle spasms, thrombocytopenia, and anemia (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported in 7 pts (including sepsis, hemorrhagic stroke, pneumonia, and disease progression). There were no reported episodes of clinical or laboratory TLS. No DLT was reported and MTD has not been reached. Of 26 AML pts evaluable for response (at least 1 cycle completed), one achieved a CRi (complete remission with incomplete blood count recovery lasting 10 months) and one a PR (partial remission lasting 3 months before proceeding to allogeneic stem cell transplant). In MDS, 4 out of 4 pts had stable disease (lasting 1 to >7 months). Bone marrow blasts decreased in 50% of all evaluable pts, with the nadir reached (87%) within the first two cycles (Figure 1).

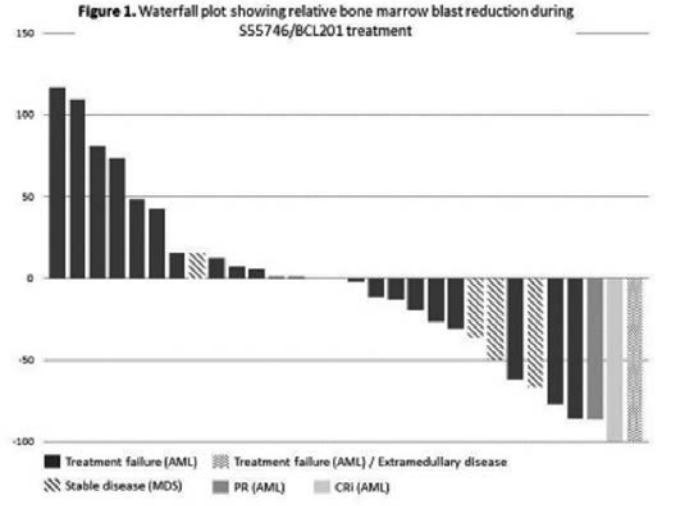

Figure 1.

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartmental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

E908

DISSECTING THE CLINICAL HETEROGENEITY OF NUCLEOPHOSMIN-1 (NPM1) MUTATED ADULT ACUTE MYELOID LEUKEMIA: THE CONTRIBUTION OF FLOW-CYTOMETRIC DETERMINATION OF MINIMAL RESIDUAL DISEASE

F. Buccisano[1,*], L. Maurillo[1], M.I. Del Principe[1], A. Di Veroli[1], E. De Bellis[1], L. Cicconi[1], M. Divona[1], T. Ottone[1], S. Lavorgna[1], V. Rossi[1], A. Zizzari[1], M.A. Irno Consalvo[1], D. Fraboni[1], C. Conti[1], G. Del Poeta[1], M.T. Voso[1], W. Arcese[1], F. Lo Coco[1], A. Venditti[1]

[1]Biomedicine and Prevention, University Tor Vergata of Rome, Rome, Italy

Background: Acute Myeloid Leukemia (AML) with mutations of the gene encoding Nucleophosmin-1 (NPM1) identifies a subgroup of patients with favorable prognosis according to the 2008 WHO classification. However, recent evidences (Papaemmanuil, NEJM 2016) suggest that the coexistence of additional gene mutations (e.g. DNMT3A, IDH1, IDH2^{R140} and TET2) may determine an inferior clinical outcome as compared to favorable risk AML and precludes a reliable outcome prediction. The presence of minimal residual disease (MRD), as determined by quantization of NPM1 mutated transcripts, provides powerful prognostic information independent of other risk factors (Ivey, NEJM 2016).
Aims: The aim of our study was to investigate if detection of MRD by multiparametric flow cytometry (MFC) might represent an alternative tool to discriminate different prognosis within the NPM1 mutated AML group, in a setting where an extensive gene profiling at diagnosis or a quantitative determination of NPM1 transcripts in remission would not be available.
Methods: We analyzed a series of 69 AML patients with NPM1 mutations; all the patients were in complete remission (CR) after intensive induction cycle of EORTC-GIMEMA protocols. The frequency of NPM1 mutated cases was not different among patients below (48/142, 34%) or above (21/61, 34%) the age of 60 years, respectively. Twenty out of 65 patients (31%) carried a concomitant FLT3-ITD mutation; 51/66 (77%) NPM1 mutated cases had a normal diploid karyotype. Upon full hematological recovery after consolidation cycle, counting, by MFC, ≥$3.5x10^{-4}$ (0.035%) residual leukemic cells (RLCs) in the bone marrow (BM) was regarded as a condition of MRD positivity.
Results: Among NPM1 mutated patients, the rate of MRD negative CR was significantly lower (5/69, 7%) as compared to NPM1 WT ones (39/134, 29%), respectively (p<0.001). Although there was not a statistically significant difference, probably due to the low numbers, MRD negative/NPM1^{mut} patients had a lower Cumulative Incidence of Relapse (CIR) as compared to MRD negative/NPM1^{wt} (25% *vs* 60%). We also evaluated the impact of autologous (AuSCT) or allogeneic (ASCT) transplantation on the outcome of MRD positive/NPM1^{mut} patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (no=14) as compared to those (no=15) submitted to AuSCT (93% *vs* 33%, p=0.011). This was confirmed even after excluding from the analysis FLT3-ITD^{mut}patients. When all the meaningful clinical variables were challenged in multivariate analysis (MRD, type of transplant, age >60 yrs, karyotype), the type of transplant (ASCT *vs* AuSCT) was the only variable that significantly influenced OS and DFS (p=0.001 and 0.003, respectively).
Summary/Conclusions: In conclusion, although quantitative RT-PCR represents the gold standard, MFC determination of MRD also confirms that the quality of remission is critical to discriminate patients with a different outcome among NPM1^{mut} patients. In fact, these patients have a low chance to become MFC MRD negative and in a situation of MRD positivity, a very poor outcome can be substantially improved only by a timely use of an allogeneic procedure.

E909

EXPRESSION OF IMMUNE CHECKPOINT MOLECULES (PD-1, PD-L1, AND PD-L2) ON BONE MARROW T CELLS IN ACUTE MYELOID LEUKEMIA

E. You[1,*], C.-J. Park[1], Y.-U. Cho[1], C.H. Yoon[1], S. Jang[1], H.J. Im[2], J.J. Seo[2], J.-H. Lee[3], K.-H. Lee[3]

[1]Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, [2]Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, [3]Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Immune checkpoints constitute a mechanism by which tumors escape from the host immune system and involve the programmed death-1 (PD-1) receptor and its ligands, PD-L1 and PD-L2. In a tumor microenvironment, overexpression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of antitumor effector cells. Recently, investigators have detected overexpression of PD-1 for patients with acute myeloid leukemia (AML) who experienced relapse following allogeneic stem cell transplantation

(SCT). However, evidence regarding T cell phenotypes for patients with AML is sparse.
Aims: The authors evaluated patients with AML to determine expression levels of checkpoint molecules (PD-1, PD-L1, and PD-L2) according to diagnosis and treatments (chemotherapy [CTx] and SCT). The purpose of this study was to identify optimal candidates for checkpoint blockade therapy for AML.
Methods: Bone marrow (BM) samples were obtained from 195 AML patients in different stages of the disease. Samples were stratified by at time of diagnosis (n=69) and treatment response (complete remission [CR] after CTx, n=30; persistence after CTx, n=29; relapse after CTx, n=7; normocellular marrow with trilineage regeneration [NMTR] after SCT, n=19; persistence after SCT, n=18; and relapse after SCT, n=23). BM samples also were collected from 23 patients with no evidence of hematologic malignancies (control group). Flow cytometric analysis of PD-1 expression on T cells and PD-L1/PD-L2 expression on leukemic cells was performed by means of a FACSCanto II system (Becton-Dickinson, Sunnyvale, CA, USA).
Results: There were no differences in levels of PD-1 expression on CD8+ and CD4+ T cells at time of AML diagnosis, compared with controls. However, PD-1 expression levels on CD4+ T cells were significantly correlated with time since diagnosis. For patients at time of diagnosis, PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT (*P*=.017 and *P*<.0001), persistence after SCT (*P*=.025 and *P*<.0001), and NMTR after SCT (*P*<.0001 and *P*<.0001). In contrast, no difference in PD-1 expression was observed between patients at time of diagnosis and patients after CTx (Figure 1). For CD4+ T cells, a significant difference was found between SCT and CTx groups, and PD-1 expression levels of groups that experienced relapse (*P*<.0001) or persistence (*P*<.0001) after SCT were significantly higher than those of patients in the CTx groups. PD-L1 and PD-L2 expression on leukemic cells at time of diagnosis was higher in secondary AML transformed from myelodysplastic syndrome than in *de novo* AML (*P*=.0001 and *P*=.039). Although PD-L1 and PD-L2 expression levels for patients at time of AML diagnosis did not differ from groups that experienced relapse or persistence after SCT, PD-L1 and PD-L2 levels for diagnosed patients did differ from those of patients who experienced persistence after CTx (*P*=.038 and *P*=.023).

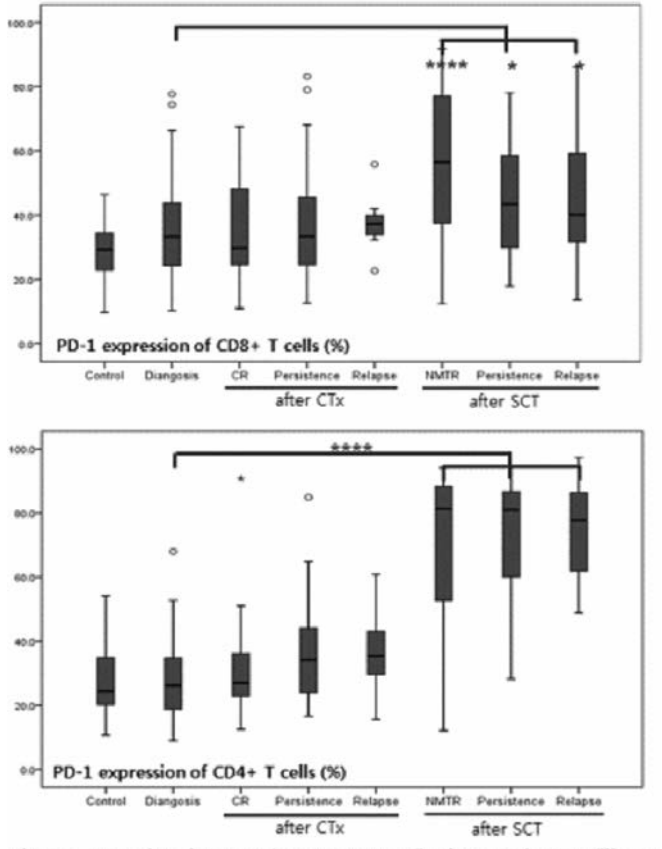

Figure 1. Expression of PD-1 on bone marrow T cells of AML patients at different stage of disease. Statistical differences were calculated to Diagonsis. *$P \leq 0.05$; **** $P \leq 0.0001$

Figure 1.

Summary/Conclusions: The present study suggests that the PD-1/PD-L1 pathway may constitute an immune-escape mechanism in AML. PD-1 expression in CD4+ T cells increased with time since diagnosis. Patients who underwent SCT exhibited overexpression of PD-1, which suggests that SCT and/or chronic stimulation of leukemic cells might induce more PD-1 expression by T cells. Blockade of the PD-1 immune checkpoint may represent an immunotherapeutic strategy for patients with AML relapse or AML persistence after SCT.

E910

ACUTE LEUKEMIA IN HIV PATIENTS : EPIDEMIOLOGY, THERAPEUTIC STRATEGY AND PROGNOSIS

F. Rabian[1,*], F. Suarez[2], T. Cluzeau[3], F. Isnard[4], C. Recher[5], A. Pigneux[6], S. Nguyen-Quoc[7], S. Chevret[8], H. Dombret[9], E. Raffoux[9]
[1]St Louis Hospital, [2]Adult Hematology Unit, Necker Hospital, Paris, [3]Adult Hematology Unit, Nice Hospital, Nice, [4]Adult Hematology Unit, St Antoine Hospital, Paris, [5]Institut universitaire du cancer, oncopole, Toulouse, [6]Hematology Unit, Hôpital Haut-Lévêque, Pessac, [7]Hematology Unit, Pitie Salpetriere Hospital, [8]Biostatistics and Medical Information, [9]Adult Hematology Unit, St Louis Hospital, Paris, France

Background: Data on HIV patients with acute leukemia (AL, acute myeloid leukemia (AML) or non Burkitt acute lymphoid leukemia (ALL)) are very poor especially on their outcome. Treatment of acute leukemia usually depends of patient-related prognostics factors and disease related prognostic factors. Because HIV patients are considered frail, they are always excluded of therapeutics protocols. There are no guidelines for their treatments.
Aims: Our aim was to precise the epidemiology, the best therapeutic strategies as well as patient's prognostics, and to compare their outcome to those of seronegative patients with AL.
Methods: We conduct a retrospective national multicentric study. HIV positive patients with a diagnosis of AML or non Burkitt ALL between January 2000 and February 2016 were included. We compared HIV patients' outcome to those of seronegative patients with AL after a propensity score matching.
Results: 47 HIV patients with a diagnosis of AL (42 AML and 5 ALL) were included. AL incidence in HIV patients (HIVP) is not different than in general population but AL occurred earlier (49.29 years [44.21 ; 57.47]) and secondary AL are more frequent (42.55%). With a global and multidisciplinary approach these patients can be treated with intensive chemotherapy resulting on good efficiency (complete remission (CR)=84.38%)) and tolerance. Based on a multivariable model, only absence of CR was associated with hazard of death (p=0.01). 8 patients (17,02% ; 7 AML and 1 ALL) received an hematopoietic stem cell transplantation. HIVP with AL 2 years overall survival (OS) was 29% CI95% [15 ; 54] for AML and 40% CI95% [14 ; 100] for ALL. There was no difference in OS between our HIVP and seronegative controls with AL after propensity score matching (HR=1.347 [0.6486-2.796]; p=0,42).

Table 1.

Parameters	Value	N	Stats	N	Stats
		5	ALL	42	AML
Age		5	36.8 [34.66;42.75]	42	50.07 [46.24;58.16]
Sex	F	0	0%	11	26.19 %
	M	5	100%	31	73.81 %
CD4 at AL diagnosis		2	254.5 [220.8;288.2]	37	347 [210;571]
VL at AL diagnosis		4	2.6 [0;5.54]	37	0 [0;2.17]
De novo AL	No	3	60%	17	40.48 %
	Yes	2	40%	25	59.52 %
Hyperleukocytosis	No	4	100%	35	83.33 %
	Yes	0	0%	7	16.67 %
	NA	1		0	
Unfavorable cytogenetic risk	No	1	33.33 %	23	62.16 %
	Yes	2	66.67 %	14	37.84 %
	NA	2		5	
Therapy	NA	0	0%	1	2.38 %
	LD chemo or 5-aza	0	0%	6	14.29 %
	ATRA ATO	0	0%	4	9.52 %
	Intensive therapy	5	100%	27	64.29 %
	Best supportive care	0	0%	4	9.52 %
CR	No	1	20%	14	33.33 %
	Yes	4	80%	24	57.14 %
HSCT	No	4	80%	35	83.33 %
	Yes	1	20%	7	16.67 %

Summary/Conclusions: Our study shows that HIV status has no prognostic impact on AL patient's outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.

E911

TEN-DAY DECITABINE AS INDUCTION THERAPY FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA FIT FOR INTENSIVE CHEMOTHERAPY

C. Zhou[1], H. Wei[1], D. Lin[1], Y. wang[1], B. Liu[1], K. Liu[1], B. Gong[1], Y. Li[1], G. Zhang[1], S. Qiu[1], R. Gu[1], S. Wei[1], X. Gong[1], Y. Mi[1], J. Wang[1,*]

[1]Institute of Hematology and Blood Diseases Hospital,Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Currently, there is no consensus regarding optimal treatment for older patients with acute myeloid leukemia (AML). Decitabine for 5 consecutive days produced a complete remission (CR) rate of 17.8% in older patients with newly diagnosed unfit AML. Ten-day regimen of decitabine induces a higher response in newly diagnosed older patients with AML considered unfit for intensive chemotherapy. But this 10-day regimen has not been tested in older fit AML before.
Aims: To investigated the efficacy and safety of the10-day decitabine regimen in older fit AML prospectively.
Methods: Twenty-one older patients (>60 years old) with newly diagnosed intermediate or adverse cytogenetic risk group AML, considered fit for intensive chemotherapy, were enrolled in a prospective clinical trial. These patients refused to take intensive chemotherapy. All patients were treated with at least one course of 10-day decitabine (20mg/m^2 daily). Patients who achieved less than 5% bone marrow blasts were subsequently treated with 5-day decitabine courses as maintenance therapy. Median age was 64 (range 60-74) years. There are was 5 patients with (23.8%), 10 (47.6%), 6 (28.6%) in favorable, intermediate and, poor-risk group, respectively, based on the NCCN guideline. All patients had an Eastern Cooperative Oncology Group performance status of 1.
Results: The overall response rate (ORR) was 57.1%, including 52.4% CR. There are no significant differences between responders and non-responders, in the following parameters, including age, LDH, DNMT3a mutation, white blood cells count in peripheral blood, or bone marrow blasts percentage. Nineteen patients experienced neutropenia during induction regimen. The lowest median white blood cell count and neutropenic time is $0.02´10^9$(0-3.05 ´10^9), 15(0-24) days, respectively. The common non-hematologic toxicities were febrile neutropenia and infections. Median overall survival (OS) of all patients was 20.7 months. One-year and two-year OSrate were 71.4% and 45.4%, respectively. Patients who responded to treatment had significantly longer OS than non-responders.
Summary/Conclusions: This indicates that the 10-day decitabine regimen may be an optimal management for older AML patients who are in intermediate or adverse cytogenetic risk group and fit for chemotherapy.

E912

INDOXIMOD IN COMBINATION WITH IDARUBICIN AND CYTARABINE FOR UPFRONT TREATMENT OF PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML): PHASE 1 REPORT

A. Emadi[1,2,3,*], N.G. Holtzman[1,2], M. Imran[1], F. El Chaer[1], M. Koka[4], Z. Singh[4], A. Shahlaee[5], E. A. Sausville[1,2,3], J. Law[1,2], S. T. Lee[1,2], A. Banerjee[1,2], A. Rapoport[1,2], M. R. Baer[1,2], V. H. Duong[1,2], D. H. Munn[6], M. Loken[7], E. Kennedy[8], N. Vahanian[8], C. Link[8]
[1]University of Maryland Greenebaum Comprehensive Cancer Center, [2]Medicine, [3]Pharmacology, [4]Pathology, University of Maryland, Baltimore, [5]Institute for Asthma and Allergy, Chevy Chase, [6]Georgia Cancer Center and Departments of Pediatrics, Medical College of Georgia, Augusta, [7]Hematologics Inc., Seattle, [8]NewLink Genetics Co., Ames, United States

Background: AML cells can acquire immune evasion and tolerance through overexpression of indoleamine 2,3-dioxygenase (IDO), which exerts immunomodulatory effects through tryptophan (Trp) catabolism and kynurenine production. By degrading Trp, IDO shifts the balance from a Trp-rich environment, which encourages T-cell proliferation and activation, to a Trp-poor environment leading to immune system suppression. We hypothesized that incorporation of indoximod, an inhibitor of the IDO pathway, into conventional remission induction and consolidation would be well tolerated without adding significant toxicity and may improve clinical outcomes of patients (pts) with newly diagnosed AML.
Aims: The primary objective of the phase 1 portion of the trial is to characterize the regimen limiting toxicities (RLT) as well as the recommended phase 2 dose (RP2D) of indoximod in combination with standard of care (SOC) chemotherapy for frontline AML treatment. A key secondary objective is to determine the minimal (or measurable) residual disease (MRD) status, as measured by multicolor flow cytometry, in pts with AML who receive indoximod in combination with SOC at the end of induction, after completion of the 1st cycle of consolidation, and before maintenance or proceeding to allogeneic stem cell transplantation (allo-HSCT).
Methods: This is a phase 1b / randomized phase 2a trial of indoximod in combination with 7+3 remission induction consisting of cytarabine (100mg/m^2/day continuous infusion for 7 days) and idarubicin (12mg/m^2/day for 3 days) and high dose cytarabine (HiDAC) consolidation, as SOC, in pts with newly diagnosed AML (NCT02835729), with a 3+3 design for the phase 1 portion. Indoximod is given orally every 8 hours starting on day 8 of induction onward. Indoximod is held on days that pts receive HiDAC consolidation, and it is discontinued 4 weeks prior to allo-HSCT. The phase 1 consists of 4 dose levels [400mg (-1), 600mg (0, starting dose), 1000mg (1), 1200mg (2)] in combination with SOC.
Results: Twelve pts have been enrolled, as of March 1, 2017. Median age is 53 (range 18-69) years, and 4 pts are female. According to 2017 European Leukemia Net risk stratification, 9 had favorable risk (3 with *DNMT3A* and 2 with low allelic ratio (<0.5) of *FLT3*-ITD) and 3 had adverse risk. No RLT was observed with the 1st and 2nd dose levels. The most frequently reported adverse events (regardless of attribution), were febrile neutropenia, diarrhea, nausea and vomiting, dyspnea, hypotension, and hypoxia. Three pts are no longer on study: 1 (dose level 0) due to inability to swallow indoximod after hypoxic respiratory failure during induction, 1 (dose level 1) withdrew consent for personal reasons after only 2 doses of indoximod, and 1 (dose level 2) was taken off due to eligibility. The remaining 9 pts are still on study; 3 pts in dose level 2 are currently receiving induction and are not evaluable. Five of 6 (83%) evaluable pts in dose levels 0 and 1 achieved complete remission (CR) after induction. All 5 pts demonstrated no evidence of MRD at levels <0.02% (MRD-neg) post-induction and remained MRD-neg post cycle 1 of HiDAC. One pt in dose level 1 with favorable risk (normal karyotype, mutations in *DNMT3A*/*NPM1*/*NRAS*) had primary refractory disease. The pt who was unable to swallow indoximod had favorable risk (normal karyotype, mutations in *DNMT3A*/*NPM1*) and achieved morphologic CR but had MRD at the end of induction, and ultimately relapsed after 2 cycles of HiDAC consolidation.
Summary/Conclusions: Indoximod does not appear to add significant toxicity to standard remission induction and consolidation in pts with newly diagnosed AML. Initial data suggest a high rate of MRD-neg after one cycle of induction chemotherapy.

E913

PHASE I/II STUDY OF MEK INHIBITOR (MEK-162; BINIMETINIB) IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MYELOID MALIGNANCIES

K. Naqvi[1,*], T. Kadia[1], G. Borthakur[1], K. Takahashi[1], P. Bose[1], N. Daver[1], Y. Alvarado[1], M. Ohanian[1], C. DiNardo[1], E. Jabbour[1], G. Garcia-Manero[1], H. Kantarjian[1], A. Patel[1], F. Ravandi[1]
[1]Department of Leukemia, UTMD Anderson Cancer Center, Houston, United States

Background: Activation of the mitogen-activated protein kinase (MAPK) signaling (RAS/RAF/MEK/ERK pathway) promotes growth and inhibits apoptosis of hematopoietic cells. Inhibition of MEK/MAPK pathway has shown antiproliferative effects in acute myeloid leukemia (AML) cell lines and AML blasts. MEK-162 is an oral, potent, selective allosteric, ATP non-competitive inhibitor of MEK1 and 2.
Aims: To study the efficacy and safety of MEK-162 in patients with advanced myeloid malignancies.
Methods: Patients with relapsed/refractory AML, not candidates for intensive chemotherapy, and patients with high risk myelodysplastic syndrome (MDS) who were resistant/intolerant to standard treatment including stem cell transplant were treated with MEK-162 twice daily every 28 days. Patients in the expansion phase had to be RAS mutated. The primary endpoint was overall response rate (ORR=CR + CRi) after 1 cycle of therapy. Survival was estimated using the Kaplan-Meier method. Safety analysis included all patients who had received at least 1 dose of MEK-162. MEK-162 dose escalation followed a 3+3 design; phase 2 had built in futility/toxicitiy boundaries. 45mg twice daily is the final dose level for expansion phase.
Results: Sixteen patients were treated (escalation=7; expansion=9): 14 AML and 2 MDS. Median age was 62 years (31-85). 56% were male; 94% had a performance status of 1-2. Median number of prior therapies was 4 (1-6). 3/16 (19%) patients had complex karyotype. 11/16 (69%) patients were RAS mutated. 10/16 patients completed a minimum of 1 cycle of MEK-162 therapy and were evaluable for response (3 at 30mg and 7 at 45mg dose). ORR was 10% (CRi in 1/10 patients). Median number of cycles administered were 2 (1-4). Median duration on therapy was 1.1 months (0.1-3.4). Median overall survival is 3.2 months (0.3-7.6). Common G3/4 toxicity included neutropenia (56%), fatigue (13%), nausea/vomiting (13%) and electrolyte abnormalities (19%). No dose limiting toxicity was reported.
Summary/Conclusions: MEK-162 shows a tolerable safety profile with an ORR of 10%. The study is currently on-going. Additional studies involving combination of MEK-162 with RAF and PI3 kinase inhibitors are ongoing.

E914

HAPLOIDENTICAL TRANSPLANTATION IS SAFE AND EFFECTIVE FOR OLDER PATIENTS WITH AML/MDS

S. Ciurea[1,*], R. Saliba[1], M. Shah[1], S. Gaballa[2], G. Rondon[1], J. Chen[1], A. Gulbis[1], W. Wallis[1], B. Oran[1], A. Alousi[1], Q. Bashir[1], S. Ahmed[1], D. Marin[1], K. Rezvani[1], E. Shpall[1], M. Qazilbash[1], U. Popat[1], I. Khouri[1], C. Hosing[1], P. Kebriaei[1], N. Daver[3], M. Konopleva[3], N. Pemmaraju[3], F. Ravandi[3], J. Cortes[3], H. Kantarjian[3], R. Champlin[1]
[1]Stem Cell Transplantation, The University of Texas MD Anderson Cancer Center, Houston, [2]Thomas Jefferson University, Philadelphia, [3]Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Acute myeloid leukemia (AML) is more common in the older population. Haploidentical stem cell transplantation (haploSCT) is a potentially cur-

ative treatment option for patients with AML and allows transplantation for patients without an HLA matched donor. Recently, the use of post-transplant cyclophosphamide-based (PTCy) GVHD prophylaxis has improved outcomes of haploSCT; however, outcomes of haploSCT in older patients remain unclear.
Aims: Here we evaluated outcomes of older patients with AML/MDS who underwent haploSCT.
Methods: We retrospectively analyzed outcomes of all 43 patients ³55 years with AML/MDS who underwent a haploSCT at our institution after year 2009. All patients were treated with fludarabine-melphalan (FM)-based conditioning regimen (melphalan 100 or 140mg/m^2) plus thiotepa 5mg/kg or 2GyTBI. Characteristics of these patients are presented in **Table 1**.

Figure 1. OS estimates according to cytogenetics and donor age generated by Cox regression adjusted for disease status at transplant.

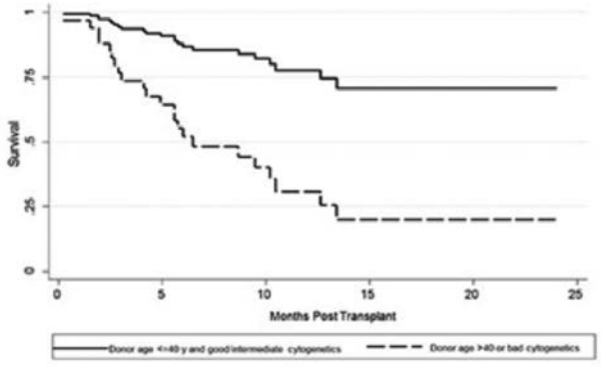

Figure 1.

Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-CI was 2 (range 0-11). Reduced melphalan regimen (100mg/m^2) was used in 29 pts (67%). Donors were children in 35 (81%) or siblings 10 (19%) patients.
Median follow-up was 19 months (range 6-49). One patient died prior to engraftment. Forty-two patients engrafted the donor cells (100%). Median time to neutrophil and platelet engraftment was 19 (13-28) and 28 (15-117) days. Day 30 chimerism was 100% donor in 38 patients (88%). The cumulative incidence (CI) of grade 2-4 and 3-4 aGVHD at 6 months post-transplant was 35% and 5% while CI of cGVHD at 2 years post-transplant was only 9%. The 2-year overall survival (OS) and progression-free survival (PFS) was 42%, and relapse rate was 24%. Cumulative non-relapse mortality (NRM) was 21%, 30% and 34% at day 100, 1 year, and 2 years post-transplant. Patients in CR1/2 had 2-year NRM and relapse rate of 23% and 14%, and OS was 61%. The 2-year OS for patients in CR1/2 with intermediate/favorable-risk cytogenetics was 73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good /intermediate cytogenetics (HR:0.2, p=0.01), and donor age greated than 40 (**Figure 1**).

Table 1.

Characteristic	N (%)
Median age	61 (55-69)
Median follow-up	19 (6-49)
Disease	
AML	25 (58%)
MDS/AML	8 (19%)
MDS	10 (23%)
Cytogenetics	
Poor	16 (37%)
Intermediate	24 (56%)

Donor age	Median 37 (20-62)
	28 (65%)
Sex mismatch	
Female donor/Male	13 (30%)
recipient	30 (70%)
Other	

Summary/Conclusions: HaploSCT with PTCy-based GVHD prophylaxis is safe and effective for older AML/MDS patients. Lack of an HLA matched donor is not a contraindication to proceeding to a haploidentical transplant in older AML/MDS patients. In addition to remission status and cytogenetics, we found that younger donor age was significantly associated with improved survival in older AML/MDS patients undergoing haploidentical transplantation.

OPTIMIZATION OF MINIMAL RESIDUAL DISEASE EVALUATION IN ACUTE MYELOID LEUKEMIA TO DRIVE POST REMISSION THERAPY

P. Minetto[1,*], F. Guolo[1], M. Clavio[1], M. Miglino[1], A. Kunkl[2], N. Colombo[1], E. Carminati[1], G. Fugazza[1], D. Guardo[1], S. Matarese[1], F. Ballerini[1], C. Di Grazia[3], A.M. Raiola[3], A. Bacigalupo[3], R.M. Lemoli[1], M. Gobbi[1]
[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Service of Flow Cytometry, Department of Pathology, [3]Division of Hematology and Bone Marrow transplantation, IRCSS AOU San Martino-IST, Genoa, Italy

Background: Among Acute Myeloid Leukemia (AML) patients achieving hematological complete remission (CR) the persistence of detectable disease assessed with highly sensitive techniques as Multicolor-Flow-Cytometry (MFC) or PCR-based molecular analysis retains a negative prognostic value. However, a consensus on the most informative time-points (TP) and sensitivity cut-offs for MRD assessment has not been reached.
Aims: The aim of the present study was the evaluation of the prognostic impact of MFC and molecular MRD assessment by identifying TP, MFC positivity cut-off values and molecular MRD markers with the highest prognostic impact.
Methods: One hundred and ten consecutive AML patients treated in our center between 2004 and 2014 were retrospectively analyzed. As previously described, all patients had received a fludarabine-containing induction.Median age was 47 years (range 18-65). Median follow up was 59 months. Three different MRD TP have been considered: TP1, after induction I; TP2, after induction II; TP3, after consolidation therapy for patients who did not undergo hematopoietic stem cells transplantation (HSCT). For patients who underwent HSCT, TP3 coincided with pre-transplant MRD evaluation. MFC-MRD evaluation had been performed through 4-colour MFC analysis (and 8-colour from 2013). To define MFC-MRD positivity two cut-offs were compared: a threshold of 2.5×10^{-4}residual leukemic cells (>0,025%) or a threshold of 1 x 10^{-3} residual leukemic cells (>0.1%). For patients carrying NPM1-gene mutation NPM1 expression levels at TP1, TP2, TP3 (NPM-MRD) were analyzed. A reduction >3.5 log of NPM1 transcript at TP1 was considered optimal as per our published experience. For patients presenting WT1 over-expression at diagnosis WT1-MRD was evaluated at TP1, considering WT1 negativity with a cut-off of WT1 copies/10^4 ABL lower than 250.
Results: CR rate after induction I and II was 82.7 and 85.5%, respectively. The percentage of MFC-MRD neg<0.025 and<0.1% increased from TP1 to TP2. The probability of achieving MFC-MRD negativity at TP2 was only influenced by ELN risk group (p <0.05). In the whole cohort, 2 years OS was 60.2% (median not reached). Multivariate Cox-Proportional Hazard model showed that MFC-MRD >0.1% at TP2 was the strongest predictor of higher risk of death, whereas MFC-MRD <0.025 at TP1 was the strongest predictor of long survival (Figure 1, a-b). However, patients with MFC-MRD >0.025 at TP1 displayed a heterogeneous outcome. In this subgroup WT1-MRD at TP1 was able to identify patients with the higher risk of death (Figure 1c). Thirty-five patients carried NPM1-mutation. Two-years OS for NPM1-mut patients showing more or less than 3.5 log transcript reduction at TP1 was 94.1% *vs* 58.3%, respectively (p 0.039); 2 years OS for patients achieving NPM1-MRD negativity at TP2 was 90.5% *vs* 42.9% (p 0.003). MFC MRD analysis in the NPM1-mut cohort led to results comparable with the whole cohort. Multivariate analysis showed that NPM1-MRD at TP1 was the strongest predictor for OS in this group.

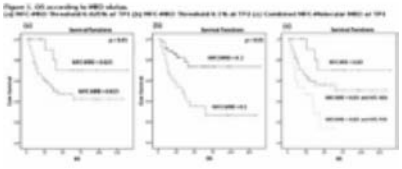

Figure 1.

Summary/Conclusions: Our data show that MRD assessment at different time-points during treatment retains a strong prognostic impact in AML and that different cut-offs at different time-points can give different and useful prognostic information that may drive post-induction therapy. MFC MRD evaluation at TP2 with 0.1% cut-off is the most useful for patients risk stratification. However, the evaluation of MFC-MRD at TP1 with 0.025% cut-off can early identify a group of patients with a significantly low risk of relapse. At the same TP, MFC and WT1 MRD integration allows a better risk stratification. MFC MRD is accurate also in NPM1-mut patients; however, in this cohort NPM1-based MRD evaluation is the most accurate predictor of prognosis.

E916

THE NUMBER OF CD34+CD38+CD117+HLA-DR+CD13+CD33+ CELLS INDICATES POST-CHEMOTHERAPY NEUTROPHIL RECOVERY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

R. GU[1], H. Wei[1], Y. Wang[1], D. Lin[1], B. Liu[1], C. Zhou[1], K. Liu[1], B. Gong[1], S. Wei[1], G. Zhang[1], X. Gong[1], Y. Liu[1], Y. Li[1], X. Zhao[1], S. Qiu[1], Y. Mi[1], J. Wang[2,*]

[1]Leukemia Center, [2]State Key laboratory of Experimental Hematology, Institute of Hematology and Blood Diseases Hospital,Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Hematopoietic recovery is considered to associated with the number of multipotent hematopoietic stem cells in the bone marrow, as observed in functional assays involving stem cell transplantation. However, there is little evidence related to hematopoietic recovery in non-transplantation settings, which is accomplished by endogenous hematopoietic cells. A recent study suggested that progenitors are the main contributors during this steady-state hematopoiesis, which differs from exogenous transplantation. And our previously data revealed that, CD34+CD38+CD117+HLA-DR+CD13+ CD33+ cells (P cells), a kind of progenitor cell, is significantly decreased in patients with delayed neutrophil recovery after chemotherapy compared with that without delayed count recovery.
Aims: To further examine a potential impact of P cells percentage on hematopoietic recovery.
Methods: The data of 223 patients diagnosed with *de novo* AML was analyzed retrospectively. All these patients enrolled in our previously registered prospective randomized clinical trial AML 2010-01(201002024). We reviewed the data from bone marrow flowcytometry before the first and second course of consolidation therapy, in which the CD34+CD38+CD117+HLA-DR+CD13+CD33+ progenitor cell percentage in the bone marrow was analyzed. Platelet recovery time and time of neutropenia were counted for the evaluation of hematopoietic recovery ability after chemotherapy.
Results: We found that less P cell percentage was significantly associated with prolonged neutropenia recovery time after the first and second courses of consolidation chemotherapy (p=0.001; p=0.028, respectively). We also observed similar results regard to platelet recovery time after the first course of consolidation chemotherapy (p=0.001). Univariate analysis showed that P cell percentage, rather than gender, age, WHO classification and cytogenetic subgroup, were associated with neutrophil recovery after chemotherapy. Multivariate analysis demonstrated that P cell percentage is an independent factor affecting neutrophil recovery capability for both first and second courses (p=0.015; p=0.036, respectively).
Summary/Conclusions: Our results indicate that CD34+CD38+CD117+HLA-DR+CD13+CD33+ cells before each course of chemotherapy is associated with chemotherapy related hematopoietic reconstitution capacity independently. These findings may help better understand endogenous hematopoietic reconstitution and modify future chemotherapy regimens based on progenitor cell percentages.

E917

MICRORNAS (MIRS) IN HIGH RISK PEDIATRIC ACUTE MYELOID LEUKEMIA (AML) AS PREDICTION TOOLS FOR RELAPSE INCIDENCE

P.P. Leoncini[1,*], P. Vitullo[1], G. Nigita[2], D. Veneziano[2], P. Fadda[3], V. Tocco[1], M. Pigazzi[4], G. Basso[4], R. Rota[1], A. Bertaina[1]
[1]Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, [2]Medical Genetics, [3]Genomic Shared Resources, Ohio State University, Columbus (OH), United States, [4]Oncohematology-Pediatrics, University of Padova, Padova, Italy

Background: Despite recent progresses made in the treatment of acute myeloid leukemia (AML) of childhood, the cure rates of high-risk subtypes remain low. Indeed, patients harboring FLT3-ITD mutations or 11q23 translocations (MLL rearrangements) are still characterized by a poor prognosis, mainly due to leukemia recurrence. Since microRNA (miRs) are small RNA molecules controlling normal hematopoiesis whose deregulation is fundamental in leukemia's pathogenesis, a possible role as predictors of relapse should be considered.
Aims: Our purpose is to identify, at time of diagnosis, significant miRs signatures able to predict the risk of relapse for patients with high-risk AML, such as FLT3-ITD and MLL mutated. Moreover, these signatures would help us in identifying new molecules for novel targeted therapy and to deeply characterize different deregulated pathways among FLT3-ITD and MLL rearranged patients.
Methods: A total of 20 AML bone marrow (BM) derived samples collected either at diagnosis (ND) and at relapse (RL) together with 8 healthy controls (HCs) were studied (total: N=48). Informed consent has been obtained from either parents or legal guardians according to the Declaration of Helsinki. RNA was extracted, cleaned up and Nanostring microRNA profiling was performed. Statistical and bioinformatics analysis were performed using nSolver™ (NanoString Technologies; Seattle, WA, USA) and R-based software. All the presented results imply a P<0.05 where not mentioned.
Results: Comparing all AML samples with HCs, we found 16 up- and 509 down-regulated miRs. Similarly, FLT3-ITD (n=11) *vs* HCs, showed 17 up- and 361 down- regulated miRs, while MLL-rearranged (n=9) *vs* HCs showed 16 and 428 up- and down- regulated miRs, respectively. A trend towards down-regulation of the whole cohort was detected and a block in miRs maturation occurring in the 2 molecular subsets was supposed. Finally, a FLT3-ITD *vs* MLL-rearranged analysis produced a signature in which 20 miRs were up- and 18 down- regulated, a putative signature which could characterize high-risk AML. ND *vs* HCs analysis identified 17 up- and 397 downregulated miRs, confirming a tendency toward downregulation, as well as in RL *vs* HCs analysis, in which we found 12 and 374 up- and down- regulated miRs, respectively. RL *vs* ND comparison showed a total of 16 up- and 15 down- regulated miRs. In the attempt to identify a signature predictive of recurrence at time of diagnosis, we compared ND and RL samples, revealing 301 miRs that maintained their deregulation in the 2 subgroups, while 113 and 85 were uniquely found in ND *vs* HCs and RL *vs* HCs, respectively. Remarkably, miR-34a-5p (P<0.0001) was the recurrent and most statistically significant upregulated miR in both ND and RL samples. Moreover, upregulated miR-10a-5p and miR-99a-5p (P<0.0001), and downregulated miR-9-5p (P<0.0001) were the most statistically significant miRs in the FLT3-ITD and MLL-rearranged sets respectively, underlying putative unique elements distinguishing the two clinical subsets.
Summary/Conclusions: Our results suggest the presence of different microRNA signatures in pediatric AML carrying FLT3-ITD and 11q23 translocations [t(9;11) and t(10;11)]. The identifications of new targets linked to this miRs would be useful for further studies focused on finding molecular-based therapy. Interestingly, miR-34a-5p was recurrently found upregulated either in ND and RL groups, but not in the comparative analysis between ND *vs* RL, suggesting a potential involvement in the mechanisms at the base of both onset and relapse in these subtypes of high-risk AML.

E918

CYTOKINE RECEPTORS AND SOLUBLE ADHESION MOLECULE LEVELS ARE ASSOCIATED WITH PROGNOSIS OF NEWLY DIAGNOSED AML

T. Kupsa[1,2], P. Zak[2], L. Jebavy[1,2], J. M. Horacek[1,2,*]
[1]Department of Military Internal Medicine and Hygiene, Faculty of Military Health Sciences, [2]4th department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, Hradec Kralove, Czech Republic

Background: The outcomes of acute myeloid leukemia (AML) treatment are beleaguered by the high resistance of malignant clones to therapy. Cytokines and adhesion molecules have been studied as markers of immune system activation in many diseases including AML. Further knowledge gained from baseline cytokine levels assessment may help to improve treatment outcomes.
Aims: The aim of this study is to evaluate baseline levels of selected cytokines, cytokine receptors and adhesion molecules and their relationship with prognosis in newly diagnosed AML patients.
Methods: A total of 75 AML patients, age 52.9±13.0 years, median 58.5 years, 44 female, were studied in the period 2010-2015. Only patients with minimal follow-up of 1 year were included. All patients were induced with "3+7" induction chemotherapy consisting of Cytarabin 100mg/m^2 per day for 7 consecutive days and Daunorubicin 90mg/m^2 for the first 3 days of therapy in younger patients. Since the beginning of 2015, the induction dose of Daunorubicin used has been 60mg/m^2 even in younger patients, according to recent evidence-based data modifications. Those who failed to achieve CR were given FlAG-Ida salvage followed by allogeneic stem cell transplantation in younger and fit patients. In CR, the patients were treated either with HiDAC consolidations alone, or followed by allogeneic stem cell transplantation in indicated cases. A total of 39 patients underwent allogeneic stem cell transplantation. We evaluated serum levels of the following 29 analytes: interleukins (IL-1α,IL-1β,IL-2,IL-3,IL-4,IL-5,IL-6,IL-7,IL-8,IL-10,IL-12,IL-13,IL-15), Epidermal Growth Factor, Granulocyte Macrophage Colony Stimulating Factor, Interferon-γ, Macrophage Inflammatory Protein-1α, Monocyte Chemotactic Protein-1, Tumor Necrosis Factor-α (TNF-α), Vascular Endothelial Growth Factor, E-selectin (E-SEL), P-selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1), Matrix Metalloproteinase-9, soluble IL-2 receptor-α (sIL-2Rα) and soluble receptors for IL-6 (sIL-6R) and TNF-α type I and II (TNFR-1,2). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox). Associations of these markers with complete remission (CR) achievement, 1 year progression-free survival (PFS), and 1 year overall survival (OS), were evaluated. Statistical analysis was performed in STATISTICA 2.0.
Results: CR by induction therapy was achieved in 53 cases (70.7%). Those who failed to achieve CR by induction therapy had higher IL-7 levels, which was not significant after Bonferroni correction (*P*=0.0913). Inferior PFS was associated with higher sIL-2Rα (*P*=0.0525). Inferior OS was significantly associated with higher P-SEL (*P*=0.0003), higher sIL-2Rα (*P*=0.0029), higher age (*P*=0.0356) and possibly with higher TNFR-1 (*P*=0.0611). Age has not correlated with any evaluated analyte. TNFR-1 correlated with TNFR-2 (P<0.0001), but not with TNF-α. The sIL-2Rα did not correlate with IL-2. Only IL-6 and ICAM-1 were significantly influenced by CRP levels.
Summary/Conclusions: Better understanding of the cancer microenvironment is a sine qua non for development of new treatment approaches. Our results show that P-SEL, sIL-2Rα and TNFR-1 may be associated with treatment outcome and thus should be further investigated as possible therapeutic targets.
The work was supported by a long-term organisation development plan 1011 (FMHS) and by MH CZ – DRO (UHHK, 00179906).

E919

MRD-DRIVEN CHOICE OF CONSOLIDATION AND MODULATION OF INDUCTION AND CONSOLIDATION INTENSITY RESULTED IN A SIGNIFICANTLY IMPROVED OUTCOME OF YOUNGER AML PATIENTS IN THE LAST THREE YEARS

M. Clavio[1,*], F. Guolo[1], P. Minetto[1], M. Miglino[1], F. Ballerini[1], D. Guardo[1], E. Coviello[1], R.M. Lemoli[1], M. Gobbi[1]
[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOU San Martino-IST, Genova, Italy

Background: In the last decades no effective new drugs have been introduced and AML induction therapy is still based on a combination of an anthracycline and cytarabine. The MRC group has, however, reported a progressive increase of cure rates in younger patients. Our group has recently showed that the outcome can be improved by a fludarabine-containing induction (FLAI5, with fludarabine administration in first course only), followed by a risk- adapted consolidation.
Aims: The aim of the present study was to evaluate if the disease free survival (DFS) and the overall survival (OS) of younger (<65 years) AML patient treated in our center had shown any modification in four consecutive periods of treatment (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result.
Methods: We reviewed the outcome of 145 consecutive AML patients aged 65 or less and uniformly treated according to the above mentioned strategy. Minimal residual disease (MRD) evaluation was performed by flow cytometry (MFC), assessment of WT1 expression levels and, where applicable, evaluation of recurrent abnormalities such as NPM1 mutation.

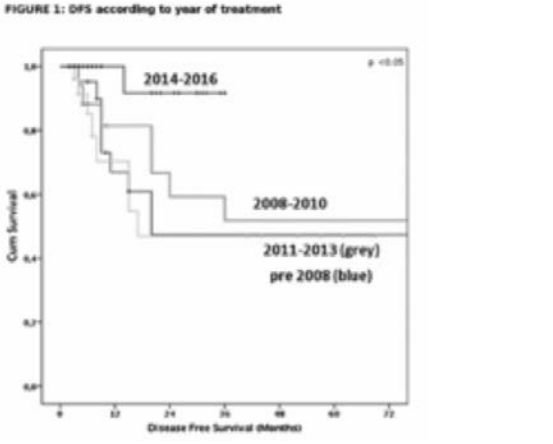

Figure 1.

Results: The cohorts of patients treated in the four periods had a comparable age and risk distribution. Notably, although the median follow up of the 4 cohorts of patients is different, patients treated in the last 3 years showed a significant improvement in DFS (Fig 1), in comparison with previously treated patients. When we reviewed our experience, we found that some changes we introduced in the therapeutic management, possibly contributed to improve outcome. Beside classical risk factors, the time from hematological recovery after the first induction (induction 1) and the start of the second induction course (induction 2) proved to be significantly related to DFS and OS probability. An interval shorter than 15 days resulted in significantly higher toxicity, whereas a time longer than 25 days was associated with an increased relapse probability. Patients being treated in the last three years had a median time from recovery after induction 1 to start of induction 2 of 17 days, compared to 22 days in the other cohorts ($p<0.05$). Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patient with negative MRD after induction 1 were no more scheduled for early allogeneic stem cell transplant (HSCT), but received an higher dose of Ara-C in each of the three consolidation cycles (12g/sqm cumulative dose *vs* 8g/sqm). Among 8 intermediate risk patients who were MFC MRD negative post FLAI and did not proceed to HSCT in first complete remission (CR1), only one relapsed whereas among 5 intermediate risk patients who underwent HSCT in CR1 because of MRD positivity no relapses have been observed. Starting from 2014, patient in CR1 not scheduled for HSCT who showed MRD reccurrence underwent salvage therapy before overt hematologic relapse, followed by HSCT consolidation. MRD-directed therapy allowed all treated patients to achieve MRD negative remission before HSCT. Finally, the improved outcome may be associated with a reduced incidence of invasive fungal infections (IFI) due to the introduction of prophylaxis with posaconazole. The lower rate of IFI contributed to the reduction in the delay between chemotherapy courses.
Summary/Conclusions: Our experience shows that, even without the contribution of new drugs, more appropriate utilization of HSCT, tailored on early MRD assessment, MRD directed salvage therapy and posaconazole prophylaxis of IFI led to a relevant improvement of outcome.

E920

EFFECTIVENESS OF TREATMENT ACUTE MYELOID LEUKEMIA IN THE ELDERLY USING CLADRIBINE WITH LOW-DOSE ARAC

M. Wątek[1,*], T. Gromek[2], A. Pluta[3], K. Budziszewska[4], D. Majowicz[2], E. Sierlecka[1], M. Hus[2], M. Pasiarski[1], S. Góźdź[5], A. Wierzbowska[3]
[1]Department of Hematology, Holy Cross Oncology Center of Kielce, Kielce, [2]Department of Hematooncology, Medical University of Lublin, Lublin, [3]Department of Hematology, Medical University of Lodz, Lodz, [4]Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, [5]Holy Cross Oncology Center of Kielce, Kielce, Poland

Background: Treatment of acute myeloid leukemia(AML) in the elderly, unfit patients is a challenge for clinical hematologists. Therapeutic management in this group of patients causes intolerance and numerous complications including early deaths. A standard treatment of low dose cytarabine (LD-AraC) or using hypomethylating therapy is not satisfying enough. Polish Adult Leukemia Group's (PALG) studies showed, that addition of cladribine to daunorubicine and cytarabine increases the complete remission rate and improves overall survival in younger patients with AML. We also proved effectiveness of cladribine combined with high dose AraC and mitoxantron in relapsed and refractory AML (1, 2). Cladribine, enhances the concentration of Ara-CTP, an active metabolite of Ara-C in leukemic cells (3). Recent data indicate that cladribine has also hypomathylating properties.
Aims: The aim of our study was to evaluate the efficacy and toxicity of cladribine in combination with LD-AraC in older AML patients.
Methods: Patients with newly diagnosed AML (excluding APL), older than 60 years, unfit for standard induction chemotherapy, were enrolled to our study. The patients were given two cycles of cladribine 5mg/m^2 i.v on days 1-5 and low-dose cytarabine 40mg/m^2 s.c on days 1-10 every 28 days followed by 2 cycles of cladribine 5mg/m^2 i.v on days 1-2 with LD-AraC (40mg/m^2 s.c 1-10 days). Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m^2 1-10 day). The treatment was continued until progression.
Results: Twenty-four patients have been enrolled with median age 70 years (range 62-84). In our cohort 20 patients had newly diagnosed AML, 3 secondary and 1 therapy related AML. Cytogenetic risk: good risk 5 patients, intermediate 12, poor risk 3 patients, 4 patients were unclassified. The overall response rate (CR+PR) was 84%. 13 out of 24 (54%) patients achieved complete remission (CR) and 7 (30%) achieved partial remission (PR). The median number of cycles to obtain CR was 2 (range 1-3). 16% of patients do not responded to treatment. The regiment was well tolerated without 4-week and 8-week mortality. The main reason of death were: heart failure (n=2), renal failure (n=1) and progressive disease (n=4). We didn't observe grade 3. and 4. nonhematologic adverse events. With a median time of follow-up 14 months, the median overall survival was 12 months.
Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regiment in elderly AML patients unfit for standard chemotherapy.

E921

SMALL CUSTOMIZABLE NGS BASED TARGET CAPTURE PANELS DETECT VARIANTS IN CLINICAL SPECIMENS AT FREQUENCIES AS LOW AS 0.5%

L. Chamberlain[1,*], A.R. Carson[1], V. McClain[1], B. Patay[1], O. Kiya[1], W. Huang[1], D. Hubbard[2], D. Caguioa[2], Z. Xie[1], J. Thornes[2], T. Stenzel[1], J.E. Miller[1]
[1]Invivoscribe, Inc., [2]LabPMM, San Diego, United States

Background: The use of large scale hybridization panels in early stages of clinical trials for novel therapies elicits a plethora of information for targeted biomarkers. However, as theraputic targets are further characterized large panels generate an overly broad set of data, compromising sensitivity in the selected biomarker subset. Therefore, once biomarker targets are identified, the use of smaller hybridization panels can facilitate specific variant detection by analyzing specific genomic regions of interest with greater sensitivity than larger gene panels and greater breadth than that available via PCR-based assays. Modifications of laboratory methods for small scale panels allow for the maintenance of high analytic quality with finely targeted panels. Our small panels (~10kb) focus on 1-4 genes, allowing for high-multiplexing of samples on sequencers, and reduced costs/processing times without compromising accuracy.
Aims: To demonstrate the sensitivity, linearity, concordance with other assays, and clinical applications of small NGS target capture panels.
Methods: Two separate next generation sequencing-target capture assays were developed with bioinformatics software under ISO13485 design control. One panel contained 3 genes, including fms related tyrosine kinase 3 (*FLT3*); the second covers only *CD274* (*PD-L1*). Libraries were made, hybridized with baits, and sequenced using the Illumina MiSeqDx. Validation was carried out by spiking in fixed amounts of mutant DNA into wild type DNA to establish the linearity and sensitivity of the assays. Sequencing libraries were generated by capturing with baits from either one or both panels. Sequencing data was analyzed using proprietary software developed by Invivoscribe. Eight AML clinical samples were cross validated for *FLT3* mutations by this small panel, amplicon based NGS assay, and capillary electrophoresis (CE) assay.

Results: DNA from 24 cell lines was assessed using both panels, confirming variants previously detected using other methods. A validation was run on the 3-gene panel using a series of contrived samples generated from cell lines containing between 0.5% and 25% variant allele frequencies for expected variants. Initial validation indicates that these small panel assays can detect mutations down to 0.5% variant allele frequencies. Assay linearity for *FLT3*/TKD detection from 0.25% to 12.5% or for *FLT3*/ITD detection from 0.5% to 25% is excellent (R^2= 0.996 and 0.998, respectively). Average sequencing coverage was high, ranging from 5,265x to 7,680x. Comparison of *FLT3* analysis of the small panel to amplicon based NGS assay and CE, *FLT3*-ITD showed complete concordance in clinical samples - and showed a strong linear relationship between calculated VAFs,and detected ITD sizes. There was also complete concordance for *FLT3*-TKD mutations in clinical samples.
Summary/Conclusions: Small hybridization panels are cost effective in detecting low-frequency variants from smaller subsets of genes while using far less DNA than individual PCR-based biomarker assays would require. Additionally, preliminary data shows great accuracy on clinical samples. These smaller assays focus on the most pertinent genes for a targeted therapy, and have the potential to greatly assist in understanding the molecular backgrounds of responders, super-responders, and non-responders, information which can help improve patient outcomes. Developing these assays with bioinformatics using the international ISO13485 design control standards makes them suitable for regulatory approval worldwide.

E922

EFFICACY BY OUTPATIENT *VS* INPATIENT ADMINISTRATION OF CONSOLIDATION: SUBGROUP ANALYSIS OF A PHASE 3 STUDY OF CPX-351 *VERSUS* 7+3 IN OLDER ADULTS WITH NEWLY DIAGNOSED, HIGH-RISK ACUTE MYELOID LEUKEMIA

J.E. Kolitz[1,*], S.A. Strickland[2], J.E. Cortes[3], D. Hogge[4], J.E. Lancet[5], S. Goldberg[6], K. Chung[7], R. Ryan[7], M. Chiarella[7], A.C. Louie[7], R.K. Stuart[8], B.C. Medeiros[9]
[1]Monter Cancer Center, Northwell Health System, Lake Success, NY, [2]Vanderbilt-Ingram Cancer Center, Nashville, TN, [3]MD Anderson Cancer Center, Houston, TX, United States, [4]Gordon and Leslie Diamond Health Care Centre, Vancouver, British Columbia, Canada, [5]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, [6]John Theurer Cancer Center at Hackensack Univ. Medical Center, Hackensack, NJ, [7]Jazz Pharmaceuticals, Palo Alto, CA, [8]Medical Univ. of South Carolina & Hollings Cancer Center, Charleston, SC, [9]Stanford University School of Medicine, Stanford, CA, United States

Background: The CPX-351 liposomal formulation delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin preferentially to leukemia cells. CPX-351 has demonstrated significantly improved overall survival (OS) *versus* cytarabine/daunorubicin (7+3) in a randomized, open-label, phase 3 study in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, *et al.* ASCO 2016). In contrast to the 7+3 regimen, which includes cytarabine continuous infusion for 7 days, CPX-351 is administered as a 90-minute infusion and thus has the potential to be given in the outpatient setting.
Aims: The current analysis of the phase 3 trial assessed the number of patients getting treated in the outpatient setting and their outcomes.
Methods: Enrolled patients were randomized 1:1 to receive 1 to 2 induction cycles of CPX-351 or 7+3; patients with complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles (CPX-351: 65 units/m^2 [cytarabine 65mg/m^2 + daunorubicin 28.6mg/m^2] on Days 1 and 3; 7+3: cytarabine 100mg/m^2/day x 5 days + daunorubicin 60mg/m^2 on Days 1 and 2). The site of administration was not protocol defined.

Table 1.

	Inpatient		Outpatient	
	CPX-351	7+3	CPX-351	7+3
Consolidation 1, n/N (%)	24/49 (49)	30/32 (94)	25/49 (51)	2/32 (6)
Median OS, months	14.72	9.26	25.43	6.87
Hazard ratio (95% CI)	0.55 (0.25, 1.21)		0.10 (0.01, 1.11)	
Consolidation 2, n/N (%)	9/23 (39)	12/12 (100)	14/23 (61)	0/12 (0)
Median OS, months	Not reached	14.31	26.32	–
Hazard ratio (95% CI)	0.45 (0.09, 2.36)		–	

Results: Few patients received induction as outpatient therapy (CPX-351 n=3/153 and 7+3 n=1/151 in each cycle). A total of 49/153 patients in the CPX-351 arm and 32/151 patients in the 7+3 arm received consolidation. In contrast to the induction cycles, a substantial proportion of patients received consolidation with CPX-351 in the outpatient setting (consolidation 1: n=25/49 [51%]; consolidation 2: n=14/23 [61%]) compared with the 7+3 chemotherapy arm (n=2/32 [6.2%] and n=0/12 [0%], respectively). For the CPX-351 arm, this resulted in a reduction in the mean number of treatment days spent in the inpatient setting (consolidation 1: 1.4 days; consolidation 2: 1.2 days) compared with 7+3 (5.3 and 5.5 days, respectively), and a reduction in the mean percentage of time spent by patients treated with CPX-351 consolidation in the inpatient setting (consolidation 1: 47.6%; consolidation 2: 39.1%) compared with the 7+3 arm (93.8% and 100%, respectively). CPX-351 consolidation was associated with numerical improvement in median OS *versus* 7+3, irrespective of administration in the inpatient or outpatient setting (Table). Median OS was not diminished when CPX-351 was administered in the outpatient (consolidation 1: 25.43 months; consolidation 2: 26.32 months) *versus* inpatient setting (consolidation 1: 14.72 months; consolidation 2: not reached). CPX-351 was associated with a manageable safety profile that was generally comparable to that of 7+3 chemotherapy, with no clinically meaningful differences in the rates of grade ≥3 treatment-emergent adverse events, including febrile neutropenia (68% *vs* 71%, respectively) and infections (55% *vs* 51%).
Summary/Conclusions: Some patients can successfully receive CPX-351 consolidation as outpatients without diminished efficacy, potentially reducing hospitalizations associated with treatment administration.

E923

MOLECULAR GENETIC TESTING PATTERNS FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) ENROLLED IN THE CONNECT® MDS/AML DISEASE REGISTRY

D. Pollyea[1,*], T. George[2], K. Foucar[2], H. Erba[3], M. Thompson[4], G. Roboz[5], D. Landau[6], J. Pagel[7], K. Seiter[8], C. Cogle[9], M. Nifenecker[10], A. Swern[10], P. Kiselev[10], M. Sugrue[10]
[1]University of Colorado Cancer Center, Aurora, [2]University of New Mexico, Albuquerque, [3]University of Alabama at Birmingham, Birmingham, [4]Aurora Research Institute, Aurora Health Care, Milwaukee, [5]Weill Cornell College of Medicine, New York, [6]University of Florida Health Cancer Center–Orlando Health, Orlando, [7]Swedish Cancer Institute, Seattle, [8]New York Medical College, Valhalla, [9]University of Florida, Gainesville, [10]Celgene Corporation, Summit, United States

Background: Recurrent mutations in AML-associated genes have prognostic value and may help guide treatment decisions. Molecular genetic testing patterns for AML in clinical practice are largely unknown. Previous results of the CONNECT MDS/AML Disease Registry (George *et al.* ASH 2016; abstract 3548) showed suboptimal adherence to WHO 2008 recommendations for AML diagnosis in a cohort of patients with newly diagnosed AML in clinical practice.
Aims: To report a detailed analysis of patterns of molecular genetic testing in patients with newly diagnosed AML in community and academic settings.
Methods: The CONNECT MDS/AML Disease Registry (NCT01688011) is a US prospective, observational cohort study of patients with newly diagnosed AML (≥55 years) or myelodysplastic syndrome (MDS). All clinical decisions are made by the treating clinicians. Data are collected, using an electronic data capture system, at screening, enrollment, and approximately quarterly throughout the duration of the patient's participation in the registry. All patients provided informed consent. Enrollment is ongoing. The current analysis evaluated the percentage of patients with AML who had undergone molecular genetic testing recommended by NCCN guidelines (*NPM1*, *FLT3-ITD*, *CEBPA*, *IDH1*, *IDH2*, *DNMT3A*, and *KIT*). Chi-square tests evaluated effects of several variables on likelihood of molecular genetic testing.
Results: Between 12 Dec 2013 and 8 Dec 2016 (data cutoff), 259 patients with AML were enrolled at 86 sites. Molecular genetic testing was reported in 67% (173/259) of patients. Likelihood of testing varied, respectively, for academic *vs* community sites (76% [70/92] *vs* 62% [103/167], *P*=.018), normal *vs* abnormal karyotype (77% [79/103] *vs* 59% [79/133], *P*=.006), age <65 *vs* ≥65 (83% [65/78] *vs* 60% [108/181], *P*=.0003), and Medicare *vs* other insurance (61% [83/137] *vs* 74% [90/122], *P*=.025). In patients who had undergone molecular genetic testing (n=173), the mutations tested varied substantially. All of the NCCN-recommended molecular genetic tests were reported in 9% (15/173) of patients, including 8% (6/79) of those with normal karyotype. Of the seven NCCN-recommended tests, *NPM1* (77%) and *FLT3-ITD* (76%) were most often reported and *DNMT3A* least often (16%).
Summary/Conclusions: Early data from the CONNECT MDS/AML Disease Registry reveal that despite molecular testing reported in 67% of patients with newly-diagnosed AML, a majority do not receive guideline-recommended testing. This prospective registry is uniquely positioned to capture changes in testing patterns as guidelines are established.

E924

PHASE 1, OPEN-LABEL, RANDOMIZED STUDY TO EVALUATE THE EFFECT OF CYTOCHROME P450 (CYP) 3A4 INHIBITION ON THE PHARMACOKINETICS (PK) AND SAFETY OF QUIZARTINIB (Q) AND ITS ACTIVE METABOLITE, AC886

J. Li[1,*], M. Kankam[2], D. Trone[3], G. Gammon[3]
[1]Daiichi Sankyo, San Diego, CA, [2]Vince & Associates, Overland Park, KA, [3]formerly Daiichi Sankyo, San Diego, CA, United States

Background: Q is a potent, selective FMS-like tyrosine kinase 3 (FLT3) inhibitor currently being investigated in Phase 3 studies in AML patients (pt) with FLT3 internal tandem duplication (ITD) mutations. Early studies showed concentration (conc)-dependent QTc prolongation and identified conc of Q, but not its active metabolite, AC886, was a significant predictor of the QTc prolonging effect(Levis, *et al.* ASH 2016). Q and AC886 are both primarily metabolized by CYP3A4. Because CYP3A4 inhibiting drugs are frequently required in the

course of AML treatment, a drug interaction study was performed to assess PK when Q is co-administered with CYP3A4 inhibitors.
Aims: The primary aim was to determine the effect of ketoconazole (K), a strong CYP3A4 inhibitor, and fluconazole (F), a moderate CYP3A4 inhibitor, on PK of Q and AC886. The secondary aim was to assess the tolerability and safety of Q co-administered with K or F.
Methods: This was an open-label, randomized, parallel-group study. Healthy subjects (HS) age 18 -55 years (yr) who provided informed consent were randomized 1:1:1 to receive K 200mg twice daily (BID), F 200mg BID, or placebo (P) BID on Days(D) 1-28. A single 30mg dose of Q was administered to all HS on D8. Plasma Q and AC886 conc were measured D8-28, using a validated liquid chromatography-tandem mass spectrometry method. PK parameters were determined using noncompartmental analysis. Steady-state (SS) drug conc, following repeated once daily dosing, were predicted using non-parametric superposition. An analysis of variance (ANOVA) was performed to assess the CYP3A4 inhibitory effect of K and F on the PK.
Results: 93 HS were enrolled (31 per arm), and 89 received Q. 75% were male, median age 32 yr (18-53). Relative to Q+P, co-administration of Q+K or Q+F increased the geometric mean (GeoMean) C_{max} of Q by 17% and 11%, and GeoMean $AUC_{0\text{-}inf}$ by 94% and 20%, respectively (Table 1 below). The GeoMean C_{max} and $AUC_{0\text{-}inf}$ of AC886 were decreased by 60% and 15%, respectively, for Q+K, and were increased by 3% and 14%, respectively, for Q+F. Apparent clearance (CL/F) of Q was 50% lower and $t_{1/2}$ of Q and AC886 were 46% and 96% longer, respectively in Q+K *vs* Q+P. CL/F of Q was 17% lower and $t_{1/2}$ of Q and AC886 were 10% and 28% longer, respectively, in Q+F *vs* Q+P. AC886 is a minor component in circulation relative to Q (approximately 25%). An increase of 86% in simulated SS Q C_{max} and 96% in SS Q $AUC_{0\text{-}24}$ was predicted following repeat daily dosing of 30mg Q+K *vs* Q+P, while a modest decrease in AC886 exposure (<20%) was predicted. The most common (≥5%) adverse events were headache (7.5%) and diarrhea (5.4%), with the majority being Grade 1/2. There were no clinically significant hematology, clinical chemistry, QTc, or vital sign observations, and no deaths or serious adverse events.

Table 1.

Table 1: Statistical Comparisons (ANOVA) of Quizartinib PK Parameters

CYP3A4 Inhibitor	PK Parameter of Quizartinib	Quizartinib + Inhibitor			Quizartinib + Placebo			Ratio of Geometric LS Mean (%)	90% CI	p-value
		n	Geometric LS Mean	SE	n	Geometric LS Mean	SE			
Ketoconazole	$AUC_{0\text{-}inf}$ (ng·hr/mL)	28	18,706	1116	29	9626	564.4	194.33	(169.08, 223.35)	<0.0001
	C_{max} (ng/mL)	29	121.4	5.422	29	103.9	4.639	116.87	(105.22, 129.82)	0.0156
Fluconazole	$AUC_{0\text{-}inf}$ (ng·hr/mL)	28	11,549	689.2	29	9626	564.4	119.98	(104.39, 137.90)	0.0323
	C_{max} (ng/mL)	28	115.7	5.261	29	103.9	4.639	111.44	(100.23, 123.90)	0.093

Abbreviations: ANOVA = analysis of variance; LS = least square; SE = standard error; PK = pharmacokinetic
Note: LS Mean: Least-square mean. Ratio of Geometric LS Mean (Q + Inhibitor/Q + Placebo)

Summary/Conclusions: Co-administration of Q with K or F was well tolerated and safe. Overall, there was an approximate 2-fold increase in Q exposure when Q was co-administered with K, which is considered clinically significant. The increase in Q exposure when Q was co-administered with F was within 20% and is not considered clinically relevant. Given the relationship between Q conc and QTc prolongation, these results support reducing Q doses by approximately one-half when taken concomitantly with a strong CYP3A4 inhibitor. No dose reduction is needed when Q is co-administered with a moderate or weak CYP3A4 inhibitor. This approach has been implemented in two ongoing Phase 3 trials of Q in FLT3-ITD mutated AML.

E925

SYSTEMATIC LITERATURE REVIEW AND INDIRECT COMPARISON OF GLASDEGIB PLUS LOW DOSE ARA-C *VERSUS* A HYPOMETHYLATING AGENT FOR ACUTE MYELOID LEUKEMIA PATIENTS INELIGIBLE FOR INTENSIVE CHEMOTHERAPY

A. Forsythe[1,*], B. Arondekar[2], G. Tremblay[1], G. Chan[2], Y. Su[2]
[1]Purple Squirrel Economics, [2]Pfizer Inc, New York, United States

Background: In a randomized phase 2 study, glasdegib (GLAS), an oral, smoothened inhibitor, combined with Low Dose ARA-C (LDAC), showed significantly better overall survival (OS) *vs* LDAC alone in previously untreated acute myeloid leukemia (AML) patients ineligible for intensive chemotherapy (NIC). Hypomethylating agents (HMAs), azacitidine (AZA) and decitabine (DEC) are considered current standard of care in this population.
Aims: To conduct an indirect treatment comparison (ITC) comparing OS for GLAS+LDAC *vs* AZA and DEC, respectively.
Methods: Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched through 12/2016 for relevant randomized controlled trials (RCTs) of GLAS, AZA and DEC in AML patients ineligible for IC. Classical frequentist ITC using the Bucher method was used to indirectly compare OS hazards ratios with 95% confidence intervals (CI) using LDAC as the common comparator.
Results: Four studies met inclusion criteria: two studies comparing AZA to LDAC: Fenaux 2010; Dombret 2015; one study comparing DEC to LDAC: Kantarjian 2012, and one study comparing GLAS+LDAC to LDAC: Cortes 2016 (Table). Fenaux 2010 study was excluded due to population differences: baseline median bone marrow blasts at 23% in Fenaux 2010 *vs* 49% in Cortes 2016. The remaining AZA and DEC studies were generally comparable in patient baseline characteristics to the GLAS study: age and cytogenic risk: age 75/73/76 years old, poor cytogenic risk 34%/37%/39%, in AZA/DEC/GLAS+LDAC, respectively. In the ITC, with LDAC as the common comparator, GLAS+LDAC compared favorably with indirect HR for OS *vs* AZA and DEC being 0.51 and 0.56, respectively, (Table 1).

Table 1.

Interventions	Study	N	OS months	HR (95% CI)
GLAS vs. LDAC	Cortes 2016	78 vs 38	8.8 vs. 4.9	0.50 (0.33-0.75)
AZA vs. LDAC	Faunaux 2010	14 vs 20	24.5 vs. 17.0	0.37 (0.12-1.13)
AZA vs. LDAC	Dombret 2015	154 vs 158	11.2 vs 6.4	0.90 (0.70-1.16)
GLAS vs. AZA	Cortes 2016 & Dombret 2015			**0.51 (0.31-0.85)**
DEC vs LDAC	Kantarjian 2012	242 vs 243	7.7 vs. 5.0	0.82 (0.68-0.99)
GLAS v DEC	Cortes 2016 & Kantarjian 2012		-	**0.56 (0.35-0.91)**

Summary/Conclusions: Using ITC, treatment with GLAS+LDAC showed significantly better OS HR than AZA and DEC in previously untreated AML patients ineligible for treatment with IC. Limitations of current analysis include mixed IC & NIC population for the AZA trial, and mixed comparator arm of both LDAC and BSC for the DEC trial. Analyses using patient-level data matching baseline characteristics across studies may enable more robust ITC.

E926

CLINICAL OUTCOMES OF CHILDHOOD ACUTE MEGAKARYOBLASTIC LEUKEMIA: THE CHILDREN CANCER HOSPITAL EGYPT 57357 EXPERIENCE

N. Maarouf[1,*], S. Mahmoud[1,2], R. Abdelaziz[1,2], L. Lehmann[3], K. Shaaban[4,5], S. Fahmy[5,6], S. Ibrahim[4,5], O. Hassanain[7], N. Nader[7], A. Elhaddad[1,2]
[1]Pediatric Oncology, 57357 CCHE, [2]Pediatric Oncology, National Cancer Institute, Cairo, Egypt, [3] Pediatric Stem Cell Transplant, Dana Farber Cancer Institute, Boston, United States, [4]Department of Clinical Pathology CCHE, 57357 CCHE, [5]Department of Clinical Pathology, National Cancer Institute, [6]Department of Clinical Pathology, [7]Department of Research CCHE, 57357 CCHE, Cairo, Egypt

Background: Acute megakaryoblastic leukemia is a rare subtype of pediatric AML occurring in both Down and non-Down syndrome patients. Down syndrome patients with M7 subtype have an excellent prognosis while non-Down syndrome patients have poor outcomes. Heterogenous cytogenetic abnormalities have been described with M7 AML and the impact of different prognostic factors on outcomes is yet to be determined.
Aims: To evaluate the prognostic significance of various cytogenetic abnormalities and minimal residual disease (MRD) by flow cytometry after induction I and correlate them with the clinical outcomes of patients with acute megakaryoblastic leukemia.
Methods: We retrospectively analyzed the data of 80 non-Down syndrome patients diagnosed with M7 AML treated at CCHE between January 2007 through December 2016. Three treatment protocols were used.
Results: The median age at diagnosis was 1.7 years (range 0.2-15). The median time to diagnosis was 1 month. The overall (OS), event free survival(EFS) and cumulative incidence of relapse at 2 years were 53.4%, 42.9% and 28.4% respectively. Sixty one patients had abnormal cytogenetic abnormalities including Trisomy 19 (n=20), 13q (n=3), Trisomy 8 (n=12), Complex karyotype (n=28), t(1;22) (n=12), MLL gene rearrangement (n=9), Trisomy 21 (n=24) but none of these had an impact on outcomes. Out of the 80 patients 56 were in complete remission post induction I. Twenty two patients had MRD<0.1% after induction I. In the univariate analysis patients with MRD <0.1% post induction I had a better OS and EFS with a lower cumulative incidence of relapse however these findings did not reach a statistical significance.
Summary/Conclusions: Acute megakaryoblastic leukemia in non-Down syndrome patients have poor outcomes irrespective of any cytogenetic abnormalities. Future direction to determining tumor biology based on molecular pathways in this disease is being considered.

E927

IDENTIFICATION OF RESISTANCE ASSOCIATED CPG METHYLATION CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY

C. Niederwieser[1,*], C. Rohde[1], H. Serve[2], W. Berdel[3], G. Ehninger[4], S. Göllner[1], L. Müller[1], C. Müller-Tidow[1]

[1]Department of Internal Medicine IV, Hematology and Oncology, University Hospital Halle, Halle, [2]Medizinische Klinik II, Universitätsklinikum Frankfurt, Frankfurt am Main, [3]Medizinische Klinik A, Universitätsklinikum Münster, Münster, [4]Medizinische Klinik und Poliklinik I, Universitätsklinikum der Technischen Universität Dresden, Dresden, Germany

Background: Acute myeloid leukemia (AML) is a heterogeneous disease associated with epigenetic alterations that can be targeted with demethylating agents to induce CR in a subgroup of patients. However, there are currently no predictive markers that reliably distinguish responder from non-responder patients. In this analysis we assessed DNA methylation changes in a group of refractory patients with AML treated either with the hypomethylating agent azacytidine followed by intensive chemotherapy or with intensive chemotherapy alone in order to identify the alterations and genes involved.
Aims: The exploration of whole genome methylation changes of azacytidine and chemotherapy treatment in refractory patients with AML guides treatment refinement.
Methods: Patients from the AML-AZA trial of the Study Alliance Leukemia were randomized to receive either azacytidine followed by chemotherapy or chemotherapy alone. Cells were harvested at baseline and 15 days after chemotherapy from 16 of the 105 patients receiving the combination and from four of the 109 patients randomized to receive chemotherapy only. Genome wide DNA methylation was analysed using a 450K Illumina array (Illumina, San Diego, USA). With a signature derived by differential blasts within diagnosis to day 15, patients with a reduction of blasts clustered together by methylation of all the selected CpG sites, as did those with an increase of blasts on both day 0 and 15, besides paired samples of day 0 and day 15 frequently clustering together as well. This led us to refine blast independent analyses. We excluded methylation changes correlating with the percentage of blasts (p=0.14, exploratory regression among blast change and median methylation change day 0 to day 15, each), since these are likely to reflect the increased lymphocyte counts on day 15 in the unsorted samples used for analysis. Motifs most strongly impacted by methylation changes were detected using the Homer software (Salk institute, San Diego, USA). Methylation changes were compared between the two groups to identify the changes associated with the use of azacytidine prior to chemotherapy.
Results: In the Azacytidine plus Chemotherapy treated group, a total of 389 differentially methylated regions (DMRs), most of which were single CpGs, were identified, 176 of which were hypermethylated and 213 hypomethylated. The most highly represented hypermethylated loci were *INSM1* (p=1e-17, 6.25% of 176 DMRs), *KLF13* (p=1e-14, 7.95%), *HIC2* (p=1e-11, 5.11%), while those most commonly hypomethylated were *NRF1* (p=1e-15, 2.82% of 213 DMR's), *MYB* (p=1e-14, 3.76%) and *STAT1* (p=1e-14, 1.88%). The chemotherapy alone group yielded 7181 DMRs, 5752 of which were hypermethylated and 1429 hypomethylated. The genes most commonly hypermethylated in these patients were *EHF(ETS)* (p=1e-226, 32.79% of 5752), *CEBPE* (p=1e-90, 10.34%), and *Jun-AP1* (p=1e-45, 6.10%), while those most commonly hypomethylated were *RUNX1* (p=1e-24, 28.34% of 1429 DMRs), *TCF4* (p=1e-21, 8.40%) and *SMAD3* (p=1e-17, 1.05%). Median overall survival did not differ between the two treatment groups, with 153 days for chemotherapy and 143 days for azacytidine/chemotherapy patients.
Summary/Conclusions: Methylation changes associated with azacytidine and chemotherapy of refractory patients were particularly found in genes previously associated with cancer and AML. DNA hypermethylation was more common after chemotherapy alone. This finding suggests that DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation levels were detected from the most resistant cells. Of note, upon Azacytidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylation in vivo.

E928

OVER-EXPRESSION OF ZEB2-AS1 LNCRNA PREDICTS POOR OUTCOMES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

X. Shi[1,2,*], J. Li[1], L. Ma[1], L. Wen[1], Q. Wang[1], H. Yao[1], C. Ruan[1], D. Wu[1,2], S. Chen[1]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Acute myeloid leukemia (AML) is a fatal hematopoietic malignancy with poor clinical outcomes characterized by blasts infiltrated in tissues.
Aims: To determine whether the antisense lncRNA namely ZEB2-AS1 would be associated with clinical outcomes, we assessed its expression in retrospective cohort with 62 *de novo* AML cases.
Methods: Relative quantitative real-time PCR analysis was employed for detecting levels of ZEB2-AS1. SYBR Green RT-PCR was performed, followed by obtaining relative threshold cycle normalized to reference GAPDH gene. Cell migration, invasion, proliferation and apoptosis tests were used to analyze biological phenotypes of AML cells after knocking down ZEB2-AS1 lncRNA by small interfering RNAs.
Results: Results showed that expression of ZEB2-AS1 lncRNA was prominently high and closely correlated with adverse clinical outcomes in AML patients, based on either modified MRC or ELN risk stratification system. Univariate analyses indicated that patients with higher expression of ZEB2-AS1 lncRNA had significant shorter 3-year overall survival (OS) (0% *vs* 68.2%, p=0.036) and disease-free survival (DFS) (25.0% *vs* 69.8%, p=0.039). In addition, Patients with higher expression of ZEB2-AS1 lncRNA had significant lower complete remission (CR) rate in response to induction chemotherapy (75.0% *vs* 27.3%, p=0.031). In patients with low levels of ZEB2-AS1 lncRNA, patients treated by allogenic hematopoietic stem cell transplantation had significant longer OS (3-year OS, 75.8% *vs* 28.6%, p=0.037) and DFS (3-year DFS, 81.8% *vs* 28.6%, p=0.049) compared to that of chemotherapy.
Summary/Conclusions: Moreover, knockdown of ZEB2-AS1 lncRNA could effectively inhibit invasion and migration in AML cells, which was closely associated with down-regulation of ZEB2 and up-regulation of E-cadherin. Collectively, although independent prognostic value for survivals was not rigorously determined, ZEB2-AS1 lncRNA may serve as candidate to improve conventional risk stratification system and contribute to evaluating therapeutic responses in AML. Furthermore, ZEB2-AS1 lncRNA could effectively modulate leukemic phenotypes of invasion and migration which may be the potential for targeted-therapy in AML.

E929

INTENSIFICATION OF ANTHRACYCLINE DURING INDUCTION AND CONSOLIDATION IS SAFE AND WELL TOLERATED IN OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA

J. Loh[1], S. Avery[1], S. Patil[1], P. Walker[1], A. Spencer[1,2], A. Wei[1,2], S. Fleming[1,*]
[1]Department of Haematology, Alfred Hospital, [2]Australian Centre for Blood Diseases, Monash University, Melbourne, Australia

Background: AML in the elderly is more susceptible to treatment failure. Treatment related mortality in elderly patients with AML is decreasing over time, and receiving chemotherapy of adequate intensity is important in treating AML in these patients. The optimal induction and consolidation approach for patients in this age group is yet to be established, however data from the HOVON group has demonstrated the benefit of anthracycline intensification during indcution in patients aged 60-65 years, while locally the Australian AML12 study demonstrated the value of anthracycline intensification during consolidation in younger adults. We have implemented a novel combination of intensified anthracycline in combination with infusional cytarabine (AraC) during induction and in combination with intermediate-dose AraC during consolidation.
Aims: To demonstrate the safety and tolerability and provide preliminary efficacy evidence for anthracycline intensification during induction and consolidation in older adults with Acute Myeloid Leukaemia.
Methods: A retrospective pilot study was done on 76 consecutive patients above the age of 55 years with newly diagnosed AML between January 2010 to June 2016 at Alfred Hospital, Melbourne, Australia. All received the 7+3 induction regime (AraC continuous infusion at dose of 100mg/m^2/day on days 1 to 7, and idarubicin at a dose of 12mg/m^2/day on days 1 to 3), with a planned consolidation with IDAC+2 (AraC 1000mg/m^2 twice daily Day 1, 3, 5, and idarubicin 12mg/m^2/day Day 1-2). Outcomes were assessed according to the Cheson criteria with cytogenetic risk assessed by the refined Grimwade MRC criteria.

Table 1.

Table 1 – Comparison with Lowenberg et al NEJM 2009 for patients 60-65

Parameter	7+3 / IDAC+2 (n=22) (intention to treat population)	HOVOK/SAKK (n=299)
Complete Remission	81%	73%
EFS at 2-years	20%	14%
DFS at 2-years	20%	27%
OS at 2-years	58%	23%
Early death (30-days)	0%	11%

Results: 76 patients, with a median age of 62 years (range 55.4-70.6 years) received the 7+3 induction with a median overall survival of 590 (range 6-1996) days and overall response rate was 52 patients (68.4%). The event-free survival median is 109 days (range 6-1988) and the relapse-free survival median is 314 days (range 4-1947). There were 9 treatment-related deaths (11.8%) within 30 days following 7+3 induction. Of 41 patients who attained complete morphological remission after induction, 29 patients (70.7%) received the planned IDAC+2 consolidation with 17 (41.5%) receiving two consolidation cycles. Of those not receiving IDAC+2, 10 patients (24.4%) received an alternative consolidation regimen and 2 patients (4.9%) did not receive consolidation. Of those receiving IDAC+2 25 (86.2%) were intermediate cytogenetic risk and 3 (10.7%) were adverse. No treatment-related deaths occurred during consolidation with IDAC+2. 20 patients (26.3%) from the whole cohort received an allogeneic stem cell transplant (SCT), and 8 patients (27.6%) of those who received the IDAC+2 consolidation regimen proceeded to an allogeneic SCT. In all IDAC+2

consolidation cycles, the median days to neutrophil recovery was 26 days (range 18-72), platelet recovery 32 days (range 17-75), and the ICU admission rate was 12.8% (range 2-10 days). 18 patients (62.1%) receiving IDAC+2 consolidation suffered disease relapse. For patients receiving IDAC+2 consolidation the median OS was 727 days (range 113-1614 days) with an EFS of 388 days (range 109-1614 days). For patients aged 60-65 years the remission rate and survival outcomes were similar to those published by Lowenberg et al.
Summary/Conclusions: Anthracycline intensification was well tolerated with low treatment related mortality and rates of ICU admission along with acceptable time to count recovery. In patients aged 60-65 outcomes were similar to published data with high-dose daunorubicin. Despite this intensive post-remission therapy approach rates of disease relapse were high highlighting the need for novel therapeutic approaches in this patient group.

E930

PROGNOSTIC IMPACT OF IDH1 AND IDH2 MUTATIONS IN LOW AND INTERMEDIATE RISK AML: A MULTICENTER RETROSPECTIVE STUDY
F. Lessi[1], M. Riva[1,*], M. Gottardi[2], F. Mosna[2], B. Luca[3], C. Minotto[4], R. Bertorelle[5], G. Semenzato[1]
[1]Department of Medicine, University of Padua, Hematology and Clinical Immunology Unit, Padova, [2]Hematology, Department of Specialty Medicine, Ospedale Santa Maria di Ca' Foncello, Treviso, [3]Education and Training Department, Azienda Ospedaliera di Padova, Padova, [4]Division of Oncology, Ospedale di Mirano, Mirano, Venice, [5]Department of Surgery, Oncology and Gastroenterology, University of Padova, Istituto Oncologico Veneto, Padova, Italy

Background: Mutations in the isocitrate dehydrogenase 1 and 2 (*IDH1* and *IDH2*) genes are common in acute myeloid leukemia (AML) but, although investigated in several studies, their prognostic significance still remains controversial.
Aims: To evaluate the prevalence and prognostic impact of IDH1 and IDH2 mutations in adult AML patients with low and intermediate-1 and 2 risk (European Leukemia Net, ELN 2010).
Methods: We retrospectively evaluated IDH1 and IDH2 mutations in 99 low and intermediate risk patients with new diagnosed AML who underwent intensive induction chemotherapy in three Italian centers.
Results: Median age for all patients was 60 years. IDH mutations were detected in 25% of our patients. 7% were IDH1 R132, 16% were IDH2 R140 and 2% R172. Median WBC count was 12,66x10^9/L in IDH wild-type, and 24,71 x10^9/L in IDH mutated. Absolute neutrophil count was 3,1x10^9/L in IDH wild-type and 0,9x10^9/L in IDH mutated, and the difference was statistically significant (p<0,001). Median bone marrow blasts, platelets count, and LDH did not differ significantly. Cytogenetic risk group according to ELN 2010 showed favorable risk in 31,4%, and intermediate (I and II) risk in 68,6%. In favorable risk group IDH mutated patients were 12%, and 13% in the intermediate risk group. IDH expression was significantly correlated neither with NPM1 mutation nor with FLT3 mutation. There were no significant differences between induction therapies in IDH mutated and unmutated patients (overall 3+7 "like" regimens in 57 patients, FLAI like regimens in 42). There were not significant differences in CR rate after induction therapy, OS and PFS between IDH mutated and unmutated patients. Median OS was 595 days in IDH mutated and 467 in IDH wild-type (p=0,67) Median PFS was 319 days in IDH mutated and 406 days in unmutated (p =0,157). We further analyzed the impact of IDH mutation in different cytogenetic risk groups: OS and PFS were not significantly different between mutated and unmutated low cytogenetic risk patients. In intermediate I and II risk patients PFS was significantly different (177 days in IDH mutated *vs* 406 days in IDH wild type, p= 0.002), but OS was not. We then evaluated patients with normal karyotype and mutated NPM1: IDH mutations had no impact on OS and PFS.
Summary/Conclusions: In this multicenter retrospective study we found that lower absolute neutrophil count at diagnosis is significantly correlated with IDH mutations as already confirmed by other groups. In terms of prognosis we only demonstrated an advantage in PFS for umutated intermediate risk patients, suggesting a negative prognostic impact of the mutations which need to be confirmed in further studies.

E931

DECITABINE COMBINED WITH HAAG REGIMEN IS AN EFFECTIVE SALVAGE TREATMENT FOR ADVANCED ACUTE MYELOID LEUKEMIA
W. Cui[1,2], Z. Jin[1], A. Sun[1], H. Qiu[1], M. Miao[1], J. Cao[1], D. Guo[1], D. Wu[1,2], X. Tang[1,2,*]
[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: As relapsed or refractory acute myeloid leukemia (AML) are known to have poor prognosis, achieving complete remission (CR) and long-term survival become extremely challenging for these patients. Reasons for the dismal prognosis rely on more frequent resistance to conventional chemotherapy and higher treatment-related mortality. Therefore, novel therapeutic approach to treat these patients were developed.
Aims: To evaluate the clinical efficacy and safety of decitabine (DAC) in combination with HAAG regimen [homoharringtonine (HHT), cytarabine (Ara-C), doxorubicin (Acla) and recombinant human granulocyte colony stimulating factor (G-CSF)] for advanced patients with AML.
Methods: hirty-six patients with advanced AML receiving DAC combined with HAAG chemotherapy in our center from December 2012 to August 2015 were enrolled in this study. Eighteen of them were refractory or relapsed AML, and another 18 patients were those who didn't achieve CR after a course of induction chemotherapy. The therapeutic responses, side effects and long-time survival were retrospectively analyzed.
Results: After a course of treatment, the rate of CR and partial response (PR) was 58.3% (21/36) and 22.2% 8/36 respectively, while the overall response rate (ORR) was 80.6% (29/36) in the cohort. For the patients with refractory or relapse AML, CR was 61.0% (11/18), PR was 22.2% (4/18), and ORR was 83.3% (15/18). While for the other not getting CR after a course of induction chemotherapy, CR was 55.6% (10/18), PR was 22.2% (4/18), and ORR was 77.8% (14/18). Grade 4 hematological toxicities were observed in all patients, and 72.2% cases experienced infection. And all non hematological side effects were mild and well-tolerated. With a median follow-up of 7.5 (0.5-33.3) months, the 1-year overall survival (OS) rate was 43.3%, 24.2% for the refractory or relapsed AML patients, and 61.6% for those not achieving CR after a course of induction chemotherapy. The difference was significantly (*P*=0.01).
Summary/Conclusions: DAC combined with HAAG regimen is safe and effective salvage treatment for advanced stage AML patients.

E932

LESS-INTENSIVE TREATMENT LEADS TO DECREASED SURVIVAL IN UNMARRIED ACUTE MYELOID LEUKEMIA PATIENTS AND PATIENTS LIVING ALONE. A DANISH NATIONAL POPULATION-BASED COHORT STUDY
L.S.G. Østgård[1,2,*], M. Nørgaard[2], B.C. Medeiros[3], L.S. Friis[4], M. Severinsen[5], C. Schöllkopf[6], C.W. Marcher[7], J.M. Nørgaard[1]
[1]Department of Hematology, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [3]School of Medicine, Stanford University, Stanford, United States, [4]Department of Hematology, Copenhagen University Hospital, Copenhagen, [5]Department of Hematology, Aalborg University Hospital, Aalborg, [6]Department of Hematology, Herlev University Hospital, Herlev, [7]Department of Hematology, Odense University Hospital, Odense, Denmark

Background: Marital status has been found to affect leukemia survival. Still, lack of individual-level socioeconomic data, cohabitation status, and treatment information prevented further investigation of underlying mechanisms. As treatment is changing towards outpatient-care, effects of social support may become even more important.
Aims: We investigated whether and how cohabitation and marital status affect chance of intensive remission-induction chemotherapy and allogeneic stem cell transplantation (HSCT), treatment response, and survival in acute myeloid leukemia (AML) patients using individualized socioeconomic and clinical data from Statistics Denmark and The Danish National Acute Leukemia Registry.

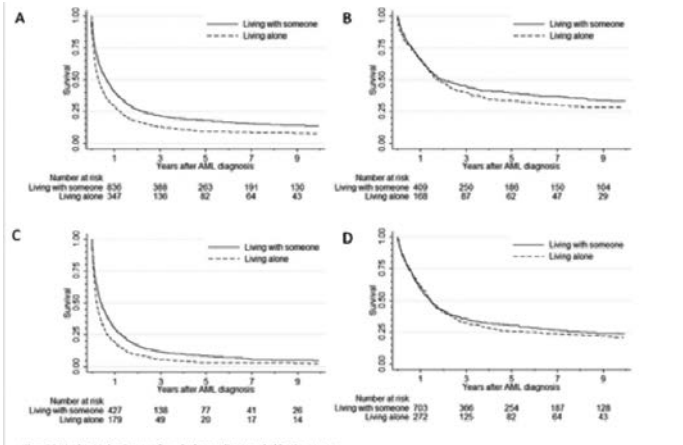

Figure 2. Kaplan Meier Curves of survival according to cohabitation status
Crude survival curves for 3243 patients by cohabitation status. In all patients (A), in patients <60 years (B), in patients ≥60 years (C), and in all patients selected for intensive therapy (D)

Figure 1.

Methods: We conducted a nationwide population-based cohort study and included all AML patients >25 years diagnosed in Denmark between 2000-2014 (follow-up ended Feb 2016). We compared chance of intensive chemotherapy, complete remission (CR) and chance of alloHSCT in CR1 by cohabitation and marital status (logistic regression, odds ratios; ORs). We used Cox regression (Hazard ratios; HRs) to compare survival. To help explain underlying mechanisms, results were given sequentially adjusted for: age, sex, income, education and occupation, and, additionally for clinical prognostic

markers. Results were given overall and stratified by age (<60/≥60 years) and sex. Kaplan Meier curves and Cox regression (Hazard ratios; HRs) was used to compare survival by cohabitation (living with someone, living alone) and marital status (married, divorced, widowed, unmarried).
Results: The study included 3243 AML patients. Patients living with someone (n=2056) were younger, more likely to be married, male, to be working, and to have a higher education than patients living alone. Comorbidity, white blood cell count, lactate dehydrogenase, and blast counts did not differ between groups, however patients living with someone tended to have better performance status at time of diagnosis. Patients living with someone were more likely to receive intensive chemotherapy than patients living alone when aged 60 years or older (41.2% *versus* 22.8%, adjusted OR 0.61 (CI=0.46-0.81)). In patients <60 years, never-married patients were less likely to receive intensive therapy (adjusted OR 0.43 (CI=0.19-0.99)) than married patients. In patients <70 years achieving CR, the chance of alloHSCT was reduced when living alone (11.8%, adjusted OR 0.47 (CI=0.28-0.78)), *versus* 19.0% in patients living with someone. In divorced/widowed, the chance was also reduced (7.6%, adjusted OR 0.38 (CI=0.20-0.74)) compared to married patients (19.3%). Crude survival by cohabitation is shown in Figure 1. Overall survival was inferior in patients ≥60 years living alone (adjusted HR 1.21 (CI=1.09-1.33)) and unmarried patients (never-married: adjusted HR 1.29 (CI=1.06-1.57), divorced/widowed: adjusted HR 1.11 (CI=1.00-1.23)) compared to married patients. In contrast, cohabitation and marital status did not affect treatment response (living with someone: CR 70.6%, living alone: CR 72.8%) or overall survival (adjusted HR 1.08 (CI=0.81-1.23)) in intensive therapy patients only.
Summary/Conclusions: Our study results indicate, that the effect of cohabitation and marital status on AML outcome, especially in patients ≥60 years, is explained by social support rather than by differences in income and occupation. Patients living alone do not present with more advanced disease or higher comorbidity burden than patients living with someone. Still, patients living alone and never-married patients are less likely to receive intensive chemotherapy affecting overall survival. Increased focus on what drives treatment decisions in patients lacking social support is important to improve survival in these patients.

E933

TREATMENT OF MOLECULAR RELAPSE IN ACUTE MYELOID LEUKEMIA WITH MUTATED NPM1 REDUCES TOXICITY OF SALVAGE TREATMENT AND IMPROVES DISEASE CLEARANCE

F. Guolo[1,*], P. Minetto[1], M. Clavio[1], D. Guardo[1], E. Coviello[1], N. Colombo[1], F. Ballerini[1], M. Miglino[1], R.M. Lemoli[1], M. Gobbi[1]
[1]Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOU San Martino-IST, Genova, Italy

Background: Acute Myeloid Leukemia with mutated NPM1 (NPM-AML) is characterized by a favorable prognosis. Most patients achieve hematological complete remission (CR) and are not considered eligible for an early allogeneic stem cell transplantation (HSCT). The importance of longitudinal NPM1 minimal residual disease (MRD) monitoring in NPM-AML is well recognized but no data are currently available on MRD-directed therapy in this AML subset. Since 2004 we have prospectically evaluated NPM1 MRD at precise time points to evaluate response to therapy and predict the risk of hematological relapse (HR).
Aims: The aim of this study was to set a standardized operative definition of molecular relapse and to evaluate the efficacy and feasibility of MRD-directed salvage therapy.
Methods: From January 2004 to January 2014, 36 consecutive younger intensively treated patients with NPM-AML achieving CR were included in the study. MRD assessment was performed on bone marrow (BM) samples after 1st and 2nd induction cycle, after each of the three consolidation cycles and then every three months for five years. If MRD positivity was found, a new analysis was to be repeated in 15 days. NPM1 mutation was measured on BM samples using MutaQuant® kit Ipsogen® from Qiagen. All Real-Time PCR were performed on DNA Engine Opticon 2. Until 2014 our policy included the treatment of leukemia in hematological relapse (HR). Salvage chemotherapy consistied in two MEC cycles and then patients proceeded to HSCT, if feasible. From January 2015 we decided to use a pre-emptive strategy, treating the molecular relapse. Four consecutive NPM-AML patients who showed MRD relapse received MRD-directed therapy so far, which consisted of one cycle of MEC.
Results: Among 36 patients, 13 showed HR, after a median of 24 months (range 14-52). All relapsing patients showed NPM MRD reccurrence prior to HR, with a median time of 4.5 months (range 1-8.4) from the first recurrence. Based on these data we defined MRD relapse as the reccurrence of NPM1 mutation, confirmed in 3 consecutive bone marrow samples repeated every 15 days, with a total increase of NPM1 expression levels of at least 2 logarithms (i.e at least from 0 to $100/10^4$Abl). All patients who fulfilled criteria for MRD relapse progressed to HR within 3 months (range 1.5-3). All 13 patients treated in HR received two cycles of MEC. Eight (62%) patients obtained hematological CR, and one patient died during therapy. Complete NPM-MRD clearance was achieved in 4/13 patients (31%). Starting from January 2015, 4 patients who met the MRD relapse criteria received pre emptive therapy, consisting of a single course of MEC. Four consecutive patients have been treated so far. Pre-chemotherapy and post-therapy disease burden, assessed by NPM levels, was significantly lower than in patients treated in HR (p <0.001, Figure 1). Both hematological and non-hematological toxicity was significantly lower than in patients treated in HR. Notably, all patients were able to achieve complete MRD clearance before HSCT and are alive and well at the time of the analysis.

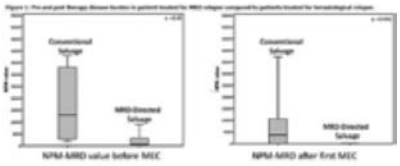

Figure 1.

Summary/Conclusions: Despite the good overall prognosis, a significant proportion of NPM-AML patients will relapse. Our preliminary data strongly support the feasibility and efficacy of MRD-directed therapy in NPM-AML. This strategy reduces the toxicity related to re-inductin and increases the proportion of patients achieving a MRD negative CR.

E934

MINIMAL RESIDUAL DISEASE AND LAIP CHANGES BY FLOW CYTOMETRY IN DE NOVO ACUTE MYELOID LEUKEMIA DURING CHEMOTHERAPY AND CLINICAL OUTCOMES

T. Lobanova[1,*], I. Galtseva[1], Y. Davydova[1], N. Kapranov[1], V. Troitskaya[1], E. Parovichnikova[1]
[1]Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemia associated immunophenotype (LAIP) changes in not explored enough.
Aims: To investigate the amount and clearance of MRD reduction and LAIP changes in *de novo* AML during chemotherapy and compare the results with clinical outcomes.
Methods: In clinical prospective study since March 2016 till February 2017 50 patients (pts) *de novo* AML (f/m 32/18 m. age 44 (17-85)) were included. 14 pts by this moment completed basic chemotherapy (ChT) courses: «7+3» 2 induction and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16,21)-1, 16q22-1, t(8,21)-2pts), intermediate-7 (6-with normal caryotype, 1-t(17,22)), poor–3 (complex karyotype-2, 11q23-1pt). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCanto II, USA) before the treatment, after 1st and 2nd courses of induction and after 2nd consolidation. Any amount of MRD >0 was assumed as MRD positivity. Besides MRD status we also explored LAIP changes in patients with CMR after 2nd ChT and in drug resistant cases.
Results: Leukemia associated immunophenotype (LAIP) was detected in all monitored patients at the diagnosis. Molecular markers were detected in 28,5% (2pts-with NPM1+FLT3+CEBPA+, 1-with FLT3+, 1-NPM1+). 2 pts had resistant AML after 2 courses (DR). 3 pts out of 7 with complete morphological remission (CMR) after 1st course had MRD positivity (0,03%, 1,61%, 8,3%), and these pts became MRD-negative after 2nd course. CMR was achieved after 2ndcourse in 5 more pts and MRD positivity was detected in 3 pts (0,033%, 0,523 and 3,9%) with intermediate cytogenetic risk. By the end of 4th course 11 pts stayed in CMR and we diagnosed 1 morphological relapse (patient with MRD-negativity and CMR after 2nd ChT). Two early relapses were also traced: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in CMR after the second course and during ChT one of them gained CD56 and CD13, 2nd- lost CD65 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn't change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.
Summary/Conclusions: 1. The most favorable group consisted of MRD negative pts after 1st course 2. LAIP changes are common in pts with less favorable prognosis.

E935

LENALIDOMIDE MAINTENANCE IN PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKEMIA

T. Kadia[1,*], J. Cortes[1], F. Ravandi[1], N. Daver[1], E. Jabbour[1], A. Ferrajoli[1], N. Pemmaraju[1], K. Naqvi[1], S. Pelletier[1], M. Brandt[1], Z. Estrov[1], H. Kantarjian[1]
[1]Leukemia, MD Anderson Cancer Center, Houston, United States

Background: New drug combinations and higher intensity therapy have led to significant improvements in complete remission (CR) rates for patients with acute myeloid leukemia (AML). However, relapsed disease remains a major source of failure. With the exception of allogeneic stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk patients. NK cells as part of the immune microenvironment are important mediators of immune surveillance in AML. Lenalidomide has demonstrated single-agent activity in AML and enhances NK cell activity and immune synapse formation in leukemia.
Aims: We designed a phase II clinical trial studying the efficacy of lenalidomide as maintenance therapy in AML patients with high-risk disease in remission, who were not being considered for SCT.
Methods: AML patients ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Patients should be within 12 months of achieving CR, have PS ≤3, adequate kidney/liver function, ANC >0.5 and platelets ≥30. Patients were treated continuously with lenalidomide 10mg PO daily on D1-28 of a 28 day cycle for up to 24 cycles. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. After cycle 1, stepwise dose escalations were allowed to 20mg daily in pts who were tolerating their dose and have presence of minimal residual or morphologically detectable disease.

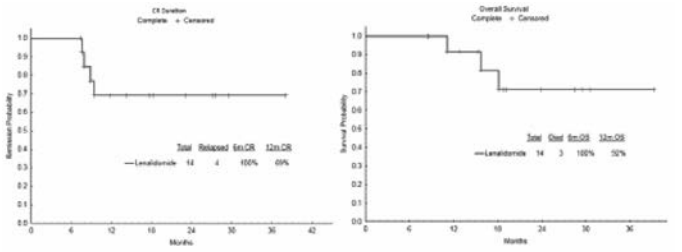

Figure 1.

Results: A total of 14 patients have been enrolled with a median age of 57.5 years (range, 23-67). All pts were in CR at the time of enrollment, with 12 pts (86%) in CR1 and 2 (14%) in CR2. Baseline pt characteristics are outlined in table 1. AML-related mutations detected at start of therapy include: CEBPA (n=5), NPM1 (3), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): 5 (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persistent MRD, 4 (29%) adverse mutational profile, 2 (14%) adverse karyotype, 1 (7%) primary refractory disease, and 2 (14%) CR2 status. Patients have received a median of 9 cycles (1-24) cycles of therapy. With a median followup of 19+ months (8.5-39), the 6- and 12-month estimated RFS were 100% and 69%, respectively. The 6- and 12-month estimated OS were 100% and 90%, respectively (Figure 1). The regimen was well tolerated. Cytopenias were mild and managed with dose adjustments. The most common grade 3 (no grade 4 toxicity) non-heme toxicities were 1 each of rash, fatigue, cough, and nausea, vomiting, and stroke.

Table 1.

Characteristic	Median (range)
Age	58 (23 - 67)
WBC [x10^9/L]	4.9 (2.5 - 9)
Platelets [x10^9/L]	119 (52 - 213)
LDH	459 (291 - 1125)
Albumin	4.2 (3.3 - 4.7)
Bilirubin	0.6 (0.2 - 1.1)
Creatinine	0.8 (0.4 - 1.2)

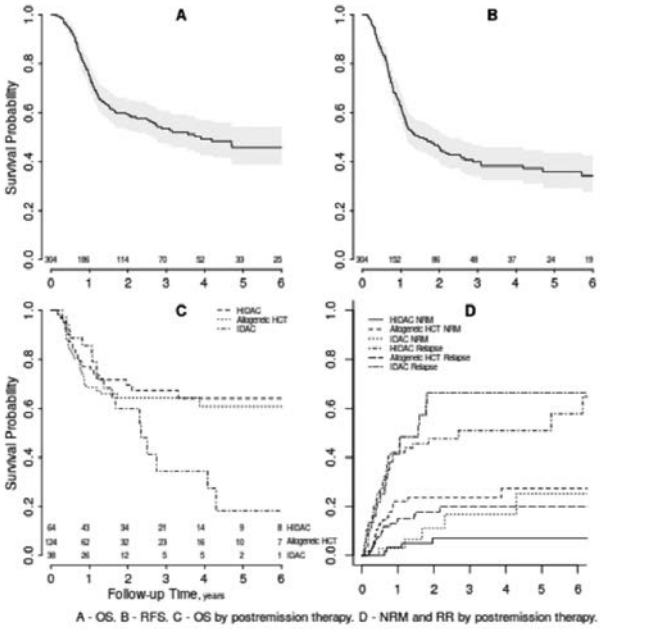
Summary/Conclusions: Lenalidomide is a safe and feasible maintenance strategy in high-risk AML patients who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of relapse-free survival of high-risk patients based on a historical cohort. Studies evaluating dynamics of MRD on study are ongoing.

E936

POSTREMISSION THERAPY FOR AML WITH INTERMEDIATE RISK CYTOGENETICS IN FIRST COMPLETE REMISSION

J. Vydra[1,*], C. Šálek[1], J. Schwarz[1], P. Cetkovský[1], P. Žák[2], J. Novák[3], V. Petečuková[3], J. Mayer[4], Z.Ráčil[4]
[1]Institute of Hematology and Blood Transfusion, Prague, [2]4th Department of Internal Medicine - hematology, Charles University, University Hospital Hradec Králové, Hradec Králové, [3]Dept. of Hematology, Charles University, University Hospital Královské Vinohrady, Prague, [4]Department of Internal Medicine/Haemato-Oncology, University Hospital Brno, Brno, Czech Republic

Background: Postremission therapy of AML with intermediate risk cytogenetics in first CR is based on chemotherapy with high dose cytarabine (HIDAC) or hematopoietic cell transplantation (HCT). Evidence from single trials with regards to optimal postremission therapy has been inconclusive, metaanalyses suggest a survival benefit of allogeneic HCT in first CR, except for patients with mutation of NPM1 without concomitant FLT3/ITD.
Aims: We analyzed retrospectively data from patients with AML with intermediate risk cytogenetics in CR1 with the aim to determine rates of completion of postremission therapy, rates and risk factors for early relapse and non relapse mortality (NRM), overall survival (OS) and relapse free survival (RFS) according to postremission treatment and describe causes of and risk factors for treatment failure.
Methods: Data on 304 patients in CR1 treated with curative intent between 2007 and 2016 in four centers participating in Czech Leukemia Study Group for Life were analyzed. All patients signed informed consent with data collection, analysis and publication. Cox regression was used to determine risk factors for OS and RFS, using time dependent covariates for postremission therapy. Age, WBC count, number of induction cycles, NPM1 mutation, FLT3/ITD, performance status, BMI, previous malignancy and extramedullary disease were included in models. Postremission therapy was completed after HCT or after three cycles of HIDAC without HCT in patients <= 60 years or two cycles of intermediate dose cytarabine (IDAC) in patients>60 years. Competing risk cumulative incidence estimates were calculated for NRM and relapse. Early relapse and NRM were defined as relapse/NRM before completion of postremission therapy.



A - OS. B - RFS. C - OS by postremission therapy. D - NRM and RR by postremission therapy.

Figure 1.

Results: Median age was 52(18-74) years. Median follow up time was 481(31-3384) days. Early relapse rate (RR) and NRM were 11.01% and 5.29%, respectively. Median OS after early relapse was only 128 days. Presence of FLT3/ITD mutation and high body mass index were associated with increased risk of early relapse on multivariate analysis (HR 14.88, 95%CI 3.24-68.43 and 2.34, 95%CI 1.3-4.2, respectively). Age increased risk of early NRM (HR 5.13, 95%CI 1.5-17.58 for age 55:35 years). 76% of patients completed therapy: 42% received allogeneic HCT in CR1, 21% completed three cycles of HIDAC and 13% completed two cycles of IDAC. 3-year OS and RFS of the whole cohort were 53.68% and 40.26%, respectively. OS was 67% in a group of patients who completed HIDAC, 34% in IDAC group and 64% in HCT group (p=0.28469). Cumulative incidence of NRM and RR 3 years after completion of therapy were 23% and 20% after HCT, 7.13% and 51% after HIDAC and 16.8% and 66.4% after IDAC, respectively, differences among groups were significant (p=0.00947 and p<0.00001). HCT reduced the risk of relapse in comparison to chemotherapy (HR 0.51, 95%CI 0.3-0.85). RFS was adversely influenced by concomitant FLT3 ITD/NPM1 mutation (HR 2.17, 95%CI 1.06-4.45). Increasing age had negative effect on OS (HR 1.65, 95%CI 1.13-2.42 for age 55:35 years). After HCT, HLA mismatch and TBI based myeloablative conditioning were associated with increased NRM [HR 6.32 (95%CI 1.89-21.14) and 6 (95%CI 1.88-19.2), respectively] in comparison to transplantation from HLA matched donors and busulphan based myeloablative conditioning.
Summary/Conclusions: The majority of patients within intermediate cytogenetic group in our analysis received allogeneic HCT. Patients who relapsed before completion of treatment had dismal outcome with very short OS. Allogeneic HCT decreased risk of relapse but led to increased NRM, reducing positive effect of HCT on OS. Risk of NRM was increased after TBI based myeloablative conditioning and after HCT from mismatched unrelated donors.

E937

LONG TERM FOLLOW UP OF PATIENTS OVER 60 YEARS TREATED WITH INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES

S. Blum[1,*], E. Schuler[2], B. Hildebrandt[3], A. Kuendgen[2], A. Giagounidis[4], G. Kobbe[2], R. Haas[2], C. Aul[5], N. Gattermann[2], U. Germing[2]
[1]Haematology, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, [2]Haematology, [3]Cytogenetics, University clinics Duesseldorf, [4]Haematology, Marien Hospital, Duesseldorf, [5]Haematology, Helios Klinikum, Duisburg, Germany

Background: More and more data on patients over the age of 60 years treated with intensive chemotherapy are emerging, however, long term data with patient outcome after the initial 2-5 years are lacking. In 2007, we published a single center study on patients over the age of 60 years, suffering from acute myeloid leukemia (AML) or high risk myelodysplastic syndrome (MDS), treated with intensive chemotherapy (Knipp *et al.* Cancer 2007, 110:345-52). We now present long term follow up data of these patients, the first patient being treated in 1991, meaning 26 years ago.
Aims: To characterize the longterm outcome of elderly AML and high risk MDS patients treated with intensive chemotherapy after the usual 2-5 year follow up period.
Methods: We treated 160 patients aged 60 years or more suffering from high risk MDS and AML with intensive chemotherapy regimen between 1991 and 2004. None of the patients underwent allogeneic stem cell transplantation afterwards. We now performed a follow up of the surviving patients 10 years after publication of the initial study.
Results: In the initial study median survival from the start of induction therapy was 9.5 months (10 days to 157 months), with the median survival from diagnosis of 14 months (1 day to 157 months). At publication of the study in the year 2007, 20 patients were still alive, 18 of them presented with a low risk karyotype. 13 of these patients were in complete remission and 7 patients had relapsed. Since then 11 of the 13 patients who were in CR relapsed and died of their leukemia. One patient died of other causes and only one patient is still alive and well, currently at the age of 84. This patient initially presented with a normal karyotype, too. As a result the rate of long term survivors 5 years after treatment is 5.6% only.
Summary/Conclusions: Long term follow up data of elderly patients treated for AML and MDS with intensive chemotherapy is scarce. Our data show, that induction chemotherapy not followed by allogeneic stem cell transplantation does not result in a meaningful improvement of outcome. In addition, morbidity and lack of quality of life has to be taken into account. More data and studies on this subject are urgently needed in an aging population. In our population of 160 treated patients, 158 died of their leukaemia, only one patient died of another cause and only one single patient is still alive and well over a decade later.

E938

FLAG-IDA FOR RELAPSED/REFRACTORY ACUTE MYELOID LEUKAEMIA: A SINGLE CENTRE 5-YEAR STUDY

C. Agbuduwe[1,*], G. Follows[1], J. Craig[1], B. Uttenthal[1], C. Crawley[1], P. Krishnamurthy[1]
[1]Haematology, Cambridge University Hospitals NHS Trust, Cambridge, United Kingdom

Background: The treatment of relapsed/refractory Acute Myeloid Leukaemia (AML) remains a formidable challenge as the therapeutic options are limited. The regimen most commonly used in this setting, FLAG-Ida (Fludarabine, cytarabine, G-CSF and idaurubicin) is considered more toxic than standard Daunorubicin plus Cytarabine (DA) regimen, often associated with prolonged periods of bone marrow suppression and predisposition to severe infections.
Aims: In this study, we present a single tertiary centre experience in the use of this regimen with a view to identifying predictive factors for survival following FLAG-ida chemotherapy. The secondary aim of this project was to assess its efficacy and safety profile in the routine clinical setting.
Methods: We conducted a retrospective chart review of patients treated with FLAG/FLAG-ida chemotherapy regimen for relapsed or refractory acute myeloid leukaemia (including secondary AML) between 2011 and 2016 in a large tertiary hospital. Patients treated with FLAG/FLAG-ida as first line therapy were excluded. Important prognostic variables including age, cytogenetics, performance status, previous chemotherapy regimen, complete response rate and overall survival were collected in an anonymized format. Informed consent was obtained as part of routine clinical care.
Results: Fifty-four patients met the criteria for inclusion in this study. The median age of the patients was 53 (10-69) years. Eighteen percent (18%) received FLAG/FLAG-ida for primary refractory AML while the remainder were treated having relapsed after at least 1 previous regimen. The median time to relapse was 15 months. Complete remission was achieved in 70% of patients and 81% of these patients proceeded to have an allogeneic stem cell transplant. The median overall survival following FLAG/FLAG-ida chemotherapy was 16 months with 1-year and 2-year survival rates of 59% and 46% respectively. Approximately 6% therapy-related mortality was observed. The median overall survival in patients with early relapse (<12 months) was significantly shorter than those with late relapse (>12 months): 6 months and 20 months respectively (log-rank test p value: 0.04) (Figure 1). Complete remission rates were similar between relapsed and primary refractory AML patients.

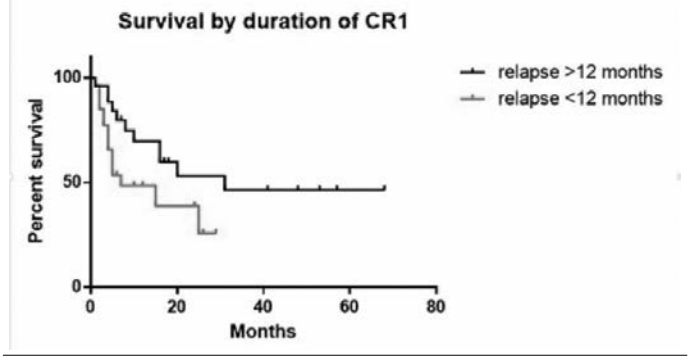

Figure 1.

Summary/Conclusions: FLAG-ida is an effective salvage regimen in patients with refractory or relapsed AML allowing the achievement of complete remission in the majority of cases. In this single-centre cohort, early relapse, within 12 months, from first line therapy was associated with an inferior survival following salvage therapy with FLAG-ida.

A MULTICENTER, RETROSPECTIVE ANALYSIS OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO WERE TREATED WITH DECITABINE

J.H. Yi[1,*], S. Park[2], J.H. Kim[3], Y.-W. Won[4], D.H. Lim[5], B.R. Han[6], J. Uhm[7], H.S. Kim[8], C.W. Jung[2], J.H. Jang[2]
[1]Hematology-Oncology, Chung-Ang university Hospital, [2]Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, [3]Hematology-Oncology, Kangnam Sacred-Heart Hospital, Hallym University Medical Center, Seoul, [4]Hematology-Oncology, Hanyang University Guri Hospital, Guri, [5]Hematology-Oncology, Dankook University College of Medicine, Cheonan, [6]Hematology-Oncology, Hallym University Medical Center, Hallym University College of Medicine, Anyang, [7]Hematology-Oncology, Hanyang University College of Medicine, [8]Hematology-Oncology, VHS Medical Center, Seoul, Korea, Republic Of

Background: While acute myeloid leukemia (AML) is the disease of the elderly, treatment options has been limited for elderly patients. Decitabine is widely accepted as the treatment options for them. However, the efficacy has yet been evaluated in Asian population where difference of clinical manifestation or cytogenetics had been noted
Aims: In the current study, we conducted a multicenter, retrospective analysis on elderly AML patients from 8 tertiary institutes in Korea who were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arisen in elderly patients.
Methods: Patients diagnosed with AML from 2013 to 2016 were included in the analysis. The inclusion criteria were as follows: (1) 65 or older patients with newly diagnosed, histologically confirmed AML (myeloid blast ≥20% either in the bone marrow or peripheral blood); (2) Treated with decitabine in a schedule of 20mg/m^2 for five days every 4 weeks in patients. The primary end-point of the study was OS. We compared our data to the data from another Korean retrospective analysis, in which elderly patients with AML were treated with best supportive care or intensive chemotherapy. (Int J Hematol 2014; 100: 141-151).
Results: A total of 80 patients were eligible for the analysis. The median age of patients was 74 years (range, 64 to 86 years) and 49 patients (61.3%) were male. Regarding the risk group, 6 (7.5%), 49 (61.2%), and 25 (31.3%) cases were classified as favorable, intermediate, and poor risk group, respectively. The patients had received median 3 (range 1-27) cycles of treatment and the median OS for all patients was 10.2 months. The median OS durations according to the cytogenetic risk group are as follows; 12.4 months (95% CI 11.4-13.4) for favorable risk group (N=6), 13.6 months (95% CI 8.7-18.5) for intermediate risk group (N=49), and 5.5 months (95% CI 1.4-9.6) for poor risk group (N=25) (p=.001). And when we categorized our cohort into two groups, that is ECOG-PS 0~2 *vs.* ECOG-PS 3 & 4, those with good performance status demonstrated improved survival (11.5 months (95% CI 6.6-16.4) *vs* 4.4 months (95% CI 2.4-6.4), p=.004). The OS curves according to prognostic factors are provided in **figure 1**. Next, we compared our data to another Korean retrospective analysis dealing with elderly AML patients who were treated with either best supportive care or intensive treatment. Although our cohort contains more patients with poor performance status and elderly patients, it seems that outcomes of decitabine treatment are fairly better than that of best supportive care (OS 3 months) and comparable to intensive chemotherapy (12.1 months).

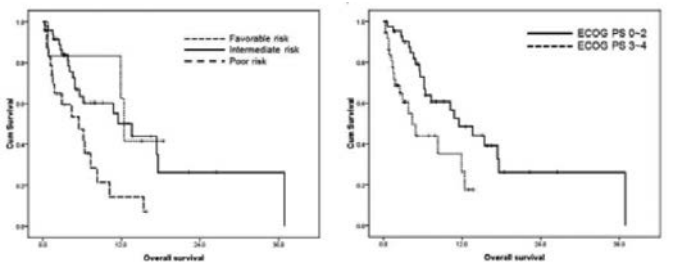

Figure 1.

Summary/Conclusions: While the treatment options for elder AML patients have been limited, our real world data suggest that decitabine could be an effective treatment of choice also in Asia

E940

DRUG-DRUG INTERACTION POTENTIAL OF GILTERITINIB IN HEALTHY SUBJECTS AND PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA

M. Levis[1,*], C. Smith[2], M. Litzow[3], A. Perl[4], J. Altman[5], A. James[6], T. Kadokura[6], B. Sargent[6], G. Yuen[6], Z. Lu[6], C. Liu[6], I. Nagase[6], E. Bahceci[6]
[1]John Hopkins University, Baltimore, [2]University of California San Francisco, San Francisco, [3]Mayo Clinic, Rochester, [4]University of Pennsylvania-Abramson Comprehensive Cancer Center, Philadelphia, [5]Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, [6]Astellas Pharma US Inc, Northbrook, United States

Background: Gilteritinib (ASP2215), a highly selective FLT3/AXL tyrosine kinase inhibitor with activity against both FLT3-ITD and FLT3-D835 mutations, is currently in development for the treatment of acute myeloid leukemia (AML). *in vitro* data suggest that gilteritinib is a CYP3A substrate as well as an inducer and weak inhibitor of CYP3A.
Aims: To evaluate drug-drug interaction potential with gilteritinib in healthy subjects and patients with relapsed/refractory (R/R) AML.
Methods: The effects of CYP3A4 inhibitors (itraconazole [ITZ] and fluconazole [FLZ]), as well as a CYP3A4 inducer (rifampin [RIF]), on the gilteritinib pharmacokinetic (PK) profile were assessed in an open-label, parallel-group study conducted in 81 healthy subjects. Gilteritinib was administered as a single 10mg dose alone on Day 6, or in combination with 200mg ITZ administered twice daily on Day 1 and once daily on Days 2–28, or in combination with once daily 400mg FLZ on Day 1 and 200mg FLZ on Days 2–28. When given concomitantly with ITZ or FLZ, gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered as a single 20-mg dose on Day 8. Additionally, the potential inhibitory effects of gilteritinib on the PK profile of a CYP3A4 substrate (midazolam) was assessed in a cohort of patients with R/R AML (n=9) in the Phase 1/2 CHRYSALIS study (NCT02014558). Patients received oral gilteritinib (300mg/d) and single oral midazolam (2mg) doses. Gilteritinib was administered on Cycle 1 Day 1 and continued once daily in 28-day cycles; midazolam was administered on Day -1 and Cycle 1 Day 15. Furthermore, in patients with R/R AML, gilteritinib trough concentration data for patients on strong (eg, voriconazole or posaconazole) or moderate (eg, FLZ) CYP3A4 inhibitors were compared with those for patients not using CYP3A4 inhibitors.

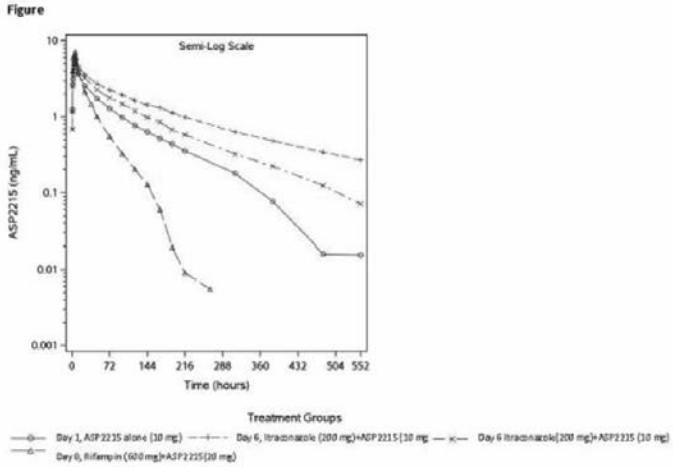

Figure 1.

Results: In healthy subjects, gilteritinib exposure (expressed as C_{max} and AUC_{24}) was higher (2.2-fold increase) in subjects who were coadministered gilteritinib with a strong CYP3A4 inhibitor (ITZ) than in subjects who were administered gilteritinib alone. Coadministration of gilteritinib with RIF, a strong CYP3A4 inducer, resulted in an approximate 70% decrease in gilteritinib exposure in healthy adult subjects (**Figure 1**). In patients with R/R AML, midazolam exposure was approximately 10% higher when administered with gilteritinib compared to midazolam alone as reflected by the geometric mean ratio and 90% confidence intervals of midazolam C_{max} (111.64%; 69.54%–179.25%) and AUC_{24} (109.46%; 49.82%–240.48%). Additionally, a <2-fold increase in gilteritinib exposure was observed in patients who were taking concomitant medications that were moderate or strong CYP3A4 inhibitors relative to patients who did not use a CYP3A4 inhibitor. The increased exposure in these patients, however, did not translate to differences in the incidence of drug-related safety events when compared across groups.
Summary/Conclusions: These data suggest limiting concomitant use of strong CYP3A4 inducers, such as rifampin, with gilteritinib. Furthermore, these data suggest coadministration of CYP3A substrates with gilteritinib is unrestricted. A comprehensive review of safety data in patients with R/R AML did not suggest that dose adjustment is warranted when gilteritinib is coadministered with strong CYP3A inhibitors. Although concomitant use of gilteritinib with strong CYP3A inhibitors (eg, ITZ or FLZ) may be permissible, precaution is warranted.

E941

A FLUDARABINE-BASED ACUTE MYELOID LEUKEMIA INDUCTION IS WELL TOLERATED UP TO 75Y OF AGE ALLOWS EARLY CONSOLIDATION AND LONG TERM SURVIVAL. A SINGLE CENTRE EXPERIENCE OF 136 CONSECUTIVE PATIENTS

E. Zappone[1], L. Aprile[1], M. Defina[1], G. Papini[1], V. Candi[1], G. Bartalucci[1], C. Zuanelli Brambilla[1], S. Ciofini[1], M. Bocchia[1,*]
[1]Hematology Unit, University of Siena, Siena, Italy

Background: For decades no effective new drugs or better anthracyclin cytarabin combinations other than the standard 3 + 7 regimen have been available for AML induction treatment. Fludarabine-based regimens have shown good efficacy in relapsed patients but raised concern about toxicity in the induction setting (Burnett JCO 2013, PMID 23940227) a modified regimen has shown better tolerance and good results in patients younger than 60 years (ys) (Guolo AJH 2016, PMID 27084986)
Aims: We report a single center, real life experience of unselected 136 consecutive AML patients treated since 2002 in our center with Fludarabine, Aracytin, Idarubicin with or without Etoposide: FLAIE up to 65ys or FLAI up to 75ys.
Methods: Patients were treated with the FLAIE or FLAI regimen followed by Idarubicin plus Aracytin as 2 step induction. Exclusion criteria for treatment were: acute promyelocytic leukemia, poor performance status and severe comorbidity. Post remission treatment included up to three cycles of high dose Aracytin, autologous (Auto) or allogeneic (Allo) stem cell transplantation according to cytogenetic and molecular risk stratification (CMR, Döhner Blood 2010 PMID 19880497) aiming for a curative strategy for all our AML patients.

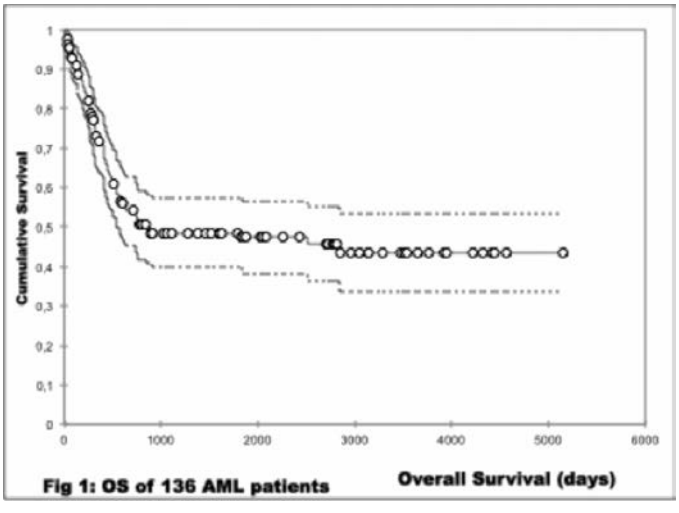

Figure 1.

Results: Median age at diagnosis was 55ys (18-75ys), median follow up was 18 months (range 3-172 months), 75% of patients (102/136) had *de novo* AML while 25% (34/136) had secondary AML mostly from myelodisplastic syndrome. 19% of patients (26/136) had good CMR risk disease, 45% of patients (61/136) had intermediate risk and 36% of patients (50/136) had high risk disease. Complete remission (CR) rate was 68% and was comparable to the majority of pub-

lished trial data, considering the proportion of high CMR risk (36%) and leukemia of secondary origin (25%) and the relatively high median age: 36% of patients (49/136) were above the 60ys old age limit of most AML protocols. In multivariate analysis CR rate was significantly affected by age below 50ys: p=0,011; good/intermediate CMR risk: p=0,011 and *de novo* AML: p=0,008. The induction death rate was 4% in line or slightly lower than published results, showing that the treatment was well tolerated; grade 3-4 non hematologic toxicity incidence was 9,6% allowing to proceed to consolidation in more than 70% of CR patients. Overall 80/136 patients (59%) were beyond 50ys, intensive condolidation with Allo or Auto was done in 34/80 patients (43%) confirming the feasibility of this therapeutic strategy. The Kaplan-Meier median probability of overall survival (OS) for the whole cohort was 28 months and factors significantly affecting OS were age below 50ys p<0,0001; *de novo* AML p<0,0003; good-intermediate CMR risk p<0,0002; intensive consolidation with Allo or Auto transplant p<0,0001 compared to chemotherapy alone. The mean probability of Leukemia free survival (LFS) was 88 months (median not reached). Patients above 50ys of age had worse outcome, the median probability of OS and LFS were 16,4 and 23,4 months respectively, this compares favorably with many published results. Chen Medicine 2016 PMID: 27472687 reported a median OS of 10,3 months in a large cohort of patients of similar age treated with intensive induction. Morevover we did not found a significant difference between the 50-59ys and 60-75ys age groups: median OS was 20,8 and 14 months (p=0,12) and median LFS was 15,9 and 23,6 months (p=0,71) respectively.
Summary/Conclusions: In our real life experience the FLAIE/FLAI regimen combined with intensive consolidation demonstrated good long term results both in terms of OS and LFS in patients younger than 50ys, this regimen was also feasible and manageble in patients beyond age of 60ys a difficult population to treat with a curative intention mainly because of concern of high toxicity of intensive induction regimens and higher incidence of poor risk prognostic factors.

E942

OVEREXPRESSION OF SOX4 CORRELATEDS WITH POOR PROGNOSIS OF ACUTE MYELOID LEUKEMIA

C.-Y. Hu[1,*], H.-A. Hou[2], C.-Y. Chen[2], H.-F. Tien[2], L.-I. Lin[1]
[1]Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, [2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

Background: The SOX4 belongs to the SOX (Sry-related high-mobility group box) family and has been characterized as a transcription factor. Over the past decade, multiple functions of SOX4 have been unveiled, and the protein is now known to play important roles in embryonic development, cell fate decision, and cellular differentiation. Overexpression and amplification of SOX4 have been implicated in various cancers and are correlated with poor prognosis. In mouse models, previous studies demonstrated that the upregulation of Sox4 can be induced by and then cooperate with the aberrant expression of AML1-ETO, NUP98-DDX10, and PML-RARa; the overexpression of HOXA9, CREB, and Evi1, and the haplosufficiency of PU.1 to trigger leukemogenesis. Furthermore, a previous study that employed retroviral transduction of Sox4 and bone marrow transplantation techniques revealed that increased Sox4 expression may cooperate with the deregulation of Mef2c expression to induce myeloid leukemia in recipient mice. Sox4 gene was also reported to be as a direct target of C/EBPα. C/EBPα is known to inhibit the self-renewal of leukemic cells and to restore cellular differentiation. The overexpression of Sox4 that results from C/EBPα inactivation contributes to the development of a type of leukemia that is characterized by a distinct leukemia-initiating cell (LIC) phenotype. This work further indicated that Sox4 is a key oncogenic target and critical mediator of C/EBPα mutants in acute myeloid leukemia (AML), which suggests a potential novel therapeutic approach to the treatment of this disease. However, the clinical implications of SOX4 expression and its role of AML leukemogenesis are not well understood.
Aims: To evaluate the relationship between bone marrow (BM) SOX4 expression and clinicopathological parameters of *de novo* AML and to evaluate the prognostic value of SOX4 expression for AML patients.
Methods: From Mar 2009 to Dec 2011, a total number of 112 adult AML patients were enrolled in this study. This study was approved by the Institutional Review Board (IRB) of the National Taiwan University Hospital (NTUH) and written informed consent was obtained from all participants in accordance with the Declaration of Helsinki. Immunocytochemical staining was used to assess SOX4 expression in bone marrow leukemic cells. All statistical analyses performed for this study involved two-tailed Student's t-tests, Mann-Whitney U tests, one-way ANOVA, Chi-square test or Fisher's exact test and multivariate analysis with Cox proportional hazards regression models. Kaplan-Meier estimation techniques were used to plot survival curves and log-rank tests.
Results: We divided AML patients into two groups according to the intensity and extent of SOX4 expression as follows: low expression group (score 0-2, n=62) and high expression group (score 3-4, n=50), respectively. The various clinical manifestations of AML did not show significant differences in terms of SOX4 expression. However, AML patients with low SOX4 expression tended to have favorable-risk cytogenetic (P=0.0866). We did not observe significant differences between the high and low expression groups in terms of age, gender, hemograms, NPM1 mutation and FLT3/ITD. Additionally, of the 112 AML patients that underwent conventional intensive induction chemotherapy, 85 (75.9%) achieved complete remission (CR), and the high and low expression groups showed similar probabilities of achieving first CR (36/50, 72% *vs* 49/62, 79%, P=0.3219). However, high SOX4 expression were associated with increased relapse rates compared to low SOX4 expression (19/36, 52.8% *vs* 13/49, 26.5%, P=0.028). Furthermore, with a median follow-up period of 46.7 months (range: 0.3 to 70.9 months), SOX4 expression was associated with overall survival (OS) and disease-free survival (DFS) in all patients with *de novo* AML (P=0.008 and P=0.013, respectively), patients with non-M3 subtypes (P<0.001 and P=0.001, respectively), patients with intermediate-risk cytogenetics, (P=0.001 and P=0.005 respectively), or even in those with normal karyotype profile (P=0.022 and P=0.111, respectively). In multivariate analysis, high SOX4 expression was found to be an independent poor prognostic factor of OS (RR 1.924, 95% CI 1.020-3.628, P=0.043) irrespective of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. A meta-analysis that we conducted using an on-line data cohort retrieved from PrognoScan (a database for meta-analysis of the prognostic value of genes; http://www.abren.net/PrognoScan/) revealed similar findings.
Summary/Conclusions: In the current study, we found that AML patients with low BM SOX4 expression had higher remission rates and longer overall survival than those with high SOX4 expression, regardless of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.

E943

AN OPEN-LABEL, MULTICENTER, PROSPECTIVE, RANDOMIZED STUDY OF RECOMBINANT HUMAN THROMBOPOIETIN AS AN ADJUNCT AFTER INTENSIVE CONSOLIDATION CHEMOTHERAPY IN ACUTE MYELOID LEUKEMIA

X.-H. Sui[1,*], Y. Li[1], X. Wang[2]
[1]Hematology department of Shandong provincial hospital affiliated to Shandong University, [2] Hematology departmentof Shandong provincial hospital affiliated to Shandong University, Shandong University school of medicine, Jinan, China

Background: Thrombocytopenia is a common problem in the management of patients with acute myeloid leukemia (AML) receiving induction and consolidation therapy. AML patients with platelet count of less than 20×10^9/l might have a high risk of bleeding complications and had to take dose modifications instead of intensive chemotherapy leading to increased disease-free survival and overall survival. Platelet transfusions have a short therapeutic effect and are associated with all types of transfusion reactions. Recombinant human thrombopoietin (rhTPO) has been shown to improve the megakaryocyte and platelet development in solid tumor patients and immune thrombocytopenia (ITP) patients refractory to glucocorticoid. We conducted this study to determine the availability of rhTPO in the platelet recovery after intensive consolidation chemotherapy with AML patients.
Aims: The aims of this study were to identify the effectiveness and safety of rhTPO in supportive care in patients with AML receiving consolidation chemotherapy.
Methods: *Patients:* Patients were eligible if they were 15□70 years of age who achieved completing remission after one course of IA induction therapy, and had platelet counts of less than 50×10^9/L after induction therapy, with an Eastern Cooperative Oncology Group (ECOG) performance status of 0~3. Patients with FAB M3 (acute progranulocytic leukemia) and FAB M7 (acute megakaryoblastic leukemia) were excluded from the study. All patients provided written informed consent according to protocol guidelines approved by the institutional review boards at their individual institutions. *Study design:* Patients received consolidation chemotherapy with DA, MA and intermediated-dose arabinosylcytosine(Ara-C), *et al.* When the platelet counts were less than or equal to 50×10^9/L, patients in study group received 15000u/day of rhTPO (trade name: TPIAO) administration subcutaneously and patients in control group not received rhTPO therapy. The administration of rhTPO continued until the platelet count was more than 100×10^9/L or for the maximum of 21 days. *Statistical analysis:* Baseline of patients' characteristics was summarized by using independent samples test and chi-square test. Other statistical data analyses were performed using the two-tailed Student's t test and were represented as means±SD of values. All differences were considered to be statistically significant when the P value was less than 0.05.
Results: There was no significant difference was observed in the main initial characteristics between study group (n=49) and control group (n=36), including age, gender and other baseline characteristics. No patient withdrew. Platelet transfusion and time required for platelet recovery were shown in **Table 1**. Platelet transfusions: The mean number and days of platelet transfusions for patients in study group were less than those in control group, but there were no significant differences of statistic status between the patients. Platelet recovery: 1. rhTPO might reduce the duration of platelet count less than or equal to 20×10^9/l and 30×10^9/l after chemotherapy. 2. rhTPO could increase the maxi-

mal and minimal platelet count after chemotherapy. 3. rhTPO might shorten the days of platelet count recover to at least 20×10^9/l from its nadir. The incidence of side effects were similar in both groups of the study.

Table 1.

Table 1. Platelet Parameters of Study Group Compared With Control Group

	Contral group N=36	Study group N=49	p value
Mean number of platelet transfusion(u)	23.08	19.24	0.154
Mean days of platelet transfusion	1.75	1.22	0.124
Mean minimal platelet count (10^9/l)	8.28	12.43	0.007
Mean maximal platelet count(10^9/l)	48.86	104.63	0.001
Mean duration time to platelet count <20×10^9/l(days)	9.36	5.63	0.008
Mean duration time to platelet count <30×10^9/l(days)	12.19	8.90	0.009
Mean duration time to platelet count <50×10^9/l(days)	13.92	11.63	0.061
Mean days to platelet recovery >=20×10^9/l from the lowest	5.28	3.59	0.048
Mean days to platelet recovery>=30×10^9/l from the minimal	7.15	5.98	0.259
Mean days to platelet recovery>=50×10^9/l from the minimal	7.08	7.56	0.690

Summary/Conclusions: rhTPO, administered as dose of 15000u/day when platelet count less than or equal to 50×10^9/l, might improve the recovery of thrombocytopenia of patients with acute myeloid leukemia in CR after consolidation chemotherapy. While there was no significant difference between study group and control group, there was a decreasing trend of platelet transfusion number and shorter time required for platelet transfusion for patients in study group.

E944

TREATMENT-ASSOCIATED SURVIVAL RATES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): A SYSTEMATIC LITERATURE REVIEW

J. Bell[1,*], A. Galaznik[2], R. Huelin[3], M. Stokes[4], D. Faller[5], R. Fram[6]
[1]Global Outcomes Research, [2]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [3]Meta Research, Evidera Inc., Waltham, United States, [4]Retrospective Observational Studies, Evidera Inc,, Dorval, Quebec, Canada, [5]Oncology Clinical Research, [6]Takeda Oncology, Cambridge, United States

Background: AML patients ≥60 years old are more likely to experience complications following intensive induction chemotherapy and are at higher risk of unfavorable outcomes compared with younger patients. Information regarding optimal treatment approaches for older AML patients is limited.
Aims: Summarize outcomes associated with therapies among older AML patients, with a focus on treatment patterns and overall survival (OS) as reported in the literature.
Methods: Searches were conducted in Medline and Embase (Jan 2014–May 2016) and supplemented by conference abstracts (2015–2016). Eligibility included studies in English reporting on treatment regimens and outcomes associated with older AML patients or subgroups thereof, and conducted in the US, EU 5 (United Kingdom, Germany, France, Spain, Italy), or Japan. Only studies enrolling ≥50 patients were included.
Results: Twelve studies (in 19 publications) reporting on OS among older AML patients were included. Participants in most studies were newly diagnosed with AML; ages ranged from 60 to 93 years. Five non-comparative studies examining the effects of various treatment modalities were identified. Median OS in studies examining azacitidine (AZA) ranged from 10 to 12 months, whereas in studies examining induction chemotherapy or reduced intensity conditioning-hematopoietic stem cell transplantation, the median OS ranged from 6.85 months (95% CI: 3.7–13.5) to 16.4 months (95% CI: 12.6–24.6), respectively. Six comparative observational studies assessed the efficacy of different treatment regimens. Intensive chemotherapy (IC) was generally associated with longer median OS compared to other regimens. In one study, median OS for patients receiving IC, lower-intensity therapy (low dose cytarabine [LD-AraC])-(AZA, decitabine), or best supportive care (BSC) was 12.4 months (95% CI: 8.5–17.4), 11.5 months (95% CI: 9.2–13.9), and 2.6 months (95% CI: 1.9–3.1), with 3-year OS rates at 27%, 17% and 6% (p<0.0001), respectively. Another study assessed the efficacy of LD-AraC relative to IC, hypomethylating agents (HMA), and BSC. Patients appeared to have longer OS when receiving IC compared to LD-AraC (median OS: 12.4 *vs* 9.6 months; 3-year OS: 27% *vs* 12%; p=0.07), and those receiving LD-AraC compared to BSC had significantly improved OS (median: 9.6 *vs* 3.4 months, p=0.001). In this same study, while OS was longer with HMA than LD-AraC, this difference was not significant (median OS 16.1 *vs* 9.6 months; 3-year OS 22% *vs* 12%, respectively; p=0.1).Two studies assessed the efficacy of AZA *vs* moderate-IC, LD-AraC, or palliative therapy, alone or in combination. AZA had a significantly better survival rate *vs* LD-AraC in poor prognosis patients (p=0.015). Furthermore, 1-year survival was higher for AZA-treated patients (67.8%) compared to those not treated with AZA (36.9%) (p=0.004). The efficacy of AZA relative to other conventional care regimens (CCRs) including BSC, LD-AraC, or standard IC was also examined in a randomized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 *vs* 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 *vs* 10.0), intermediate risk (13.0 *vs* 10.1), and high risk (6.4 *vs* 3.2), respectively.

Table 1.

Summary/Conclusions: Among older AML patients, IC tended to be associated with improved OS compared with other CCRs. However, evidence from this review indicates that AZA could be an alternative treatment option for older AML patients, whether fit or unfit for IC.

E945

SYSTEMATIC REVIEW OF HEALTH STATE UTILITY VALUES FOR ECONOMIC EVALUATION OF ACUTE MYELOID LEUKEMIA

A. Forsythe[1,*], V. Bal [2], M. Dolph [3], S. Patel [4], G. Tremblay[5]
[1]Purple Squirrel Economics, New York, [2]Novartis Pharma, East Hanover, United States, [3]Purple Squirrel Economics, Montreal, Canada, [4]Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom, [5]Purple Squirrel Economics, Quebec city, Canada

Background: Cost-utility analyses undertaken to inform decision making regarding acute myeloid leukemia (AML) require a set of health state utility values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY).
Aims: This study reviews AML-related HSUVs that could be used in economic evaluation and assesses their advantages and disadvantages with respect to valuation methods used and AML clinical pathways.
Methods: Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched from Jan 2000 through Nov 2016 for relevant studies that reported quality of life (QOL) and HSUV in AML. Identified relevant EORTC Quality of Life Core Questionnaire QLQ-C30 values were mapped to HDUV using previously published algorithm by Crott, *et al.* 2010. HSUV for induction, consolidation, complete remission (CR), relapse, stem cell therapy (SCT) treatment, SCT recovery and CR post SCT were identified.
Results: Ten relevant studies were identified. Six were cost effectiveness analyses utilizing HSUVs for calculation of Quality Adjusted Life years (QALY), one effectiveness analysis (incremental QALY), two QOL studies reporting specific AML utilities (either collected or mapped from QLQ-C30). An additional study reported QOL for patients undergoing SCT. Since no study reported HSUV for relapse, values from study of secondary AML patients who failed prior treatment for Myelodysplastic Syndrome, were used. Where multiple HSUVs were available, priority was made for collected values *vs* assumption. Identified HSUV are presented in Figure. AML treatment (both induction, consolidation and SCT) was associated with decreased HSUV, while post-treatment CR lead to increased HSUV.

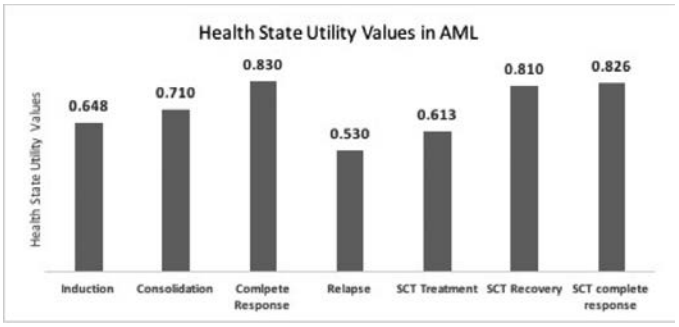

Figure 1.

Summary/Conclusions: There are relatively few methodologically robust HSUVs that can be directly used in economic evaluations concerned with AML. Careful interpretation of published values is advised considering difference in studies methodologies and patient populations. There is need to develop new HSUVs which improve on those currently available either by utilizing time trade off studies or by making greater use of condition-specific data and further use of mapping algorithms.

Panico, Tricase, [5]Unit of Hematology,USL11, Empoli, [6]Unit of Hematology, Azienda Ospedaliera Careggi, Firenze, [7]Unit of Hematology, AUSL della Romagna, Ravenna, [8]Hematology Unit, Ospedale Mazzone, Ascoli Piceno, [9]Hematology Unit, Ospedale Infermi, AUSL Romagna, Rimini, [10]Hematology Unit, University of Pisa, Pisa, Italy

Background: Acute Myeloid Leukemia (AML) has a higher incidence among the elderly population. Older patients (pts) with AML have a worse prognosis and limited treatment options. Hypomethylating agent decitabine was recently approved by FDA and EMEA as first line treatment in AML pts older than 65 yrs and unfit to receive standard cytotoxic chemotherapy. Decitabine showed to be superior to supportive care or low dose cytarabine in controlled randomized clinical studies (Kantarjian, JCO 2012; Cashen, JCO 2010).
Aims: In July 2016 we approved a retrospective and prospective multicentric observational study to investigate efficacy and tolerability of decitabine at the approved schedule of 20mg/m^2 daily for 5 days of a 4-week cycle in real life (DEA65 study). The primary objective was the assessment of overall survival (OS). Secondary objectives were evaluation of adverse events (AEs) and response rate: complete remission (CR), CR with incomplete platelets or white blood cells (WBCs) count recovery (CRi), partial remission (PR) and hematological improvement with transfusion independence. We here present an interim analysis of the first 56 pts enrolled.
Methods: AML pts older than 65 yrs treated in first line with decitabine were enrolled in the study. At diagnosis and during follow-up, cytogenetic and molecular assessment was performed by each center according to local guidelines for AML management in elderly pts.
Results: Biologic and clinical data of 56 pts, with a median age of 73 yrs (range 65-90 yrs) are reported. Thirty-one patients (55,3%) had a secondary AML and 13/31 (42%) were progressed MDS previously treated with 5-azacitidine. Median WBCs count was 3050/µL (range 770-131500/µL) with 13/56 (23%) pts with WBCs>10000/µL. Cytogenetic analysis was performed in 52/56 pts, and in 24/56 (43%) molecular analysis including FLT3 and NPM1 mutations was performed. According to prognostication, 50% of pts had a high risk, 34% an intermediate risk, 9% a low risk AML and in 4/56 (7%) pts risk was unknown. Median OS was 7 months (range 1-19 months) with 34/56 deaths (60,7%) and a median of 6 cycles (range 1 to 19) of decitabine. Overall response rate was 60,7% (34/56 pts), of which 7/56 (12,5%) CR or Cri; 17/56 (30,4%) PR and 10/56 (17,8%) improvement of transfusion needs. According to response, median OS was 9,5 months (range 4-19) and 4 months (range 1-15) in responder *vs* not responder pts. Table 1 shows response rate according to pts characteristics. At present time 18/22 alive pts are still on treatment with decitabine. Regarding toxicity, 23/56 (41%) pts manifested a grade ≥3 AEs although severe comorbidities (cardiovascular and metabolic) pre-existed in 14/23 (60,9%). A total of 35 hospitalization episodes due to toxicity were recorded and 10/56 pts (17.8%) died due to serious AEs. Overall the most common non-hematologic AEs were pneumonia and fever.

Table 1.

Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 *vs* 55 pts) showed in our cohort, a poorer rate of CR+CRi with a negative impact of secondary AML, previous 5-azacitidine therapy, WBC >10000/µL as well as high cytogenetic risk. This apparent contradiction supports the idea that in elderly pts recovery of peripheral blood cells counts (PR+hematological improvement) is probably the most important factor influencing OS (Ferrara, Hemat 2016).

E947

ASPARAGINASE ERWINIA CHRYSANTHEMI EFFECTIVELY DEPLETES PLASMA GLUTAMINE, HAS CLINICAL ACTIVITY, AND IS WELL TOLERATED IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

A. Emadi[1,2,3,*], E.T. Strovel[4], R.G. Lapidus[1,2], L.J. Jeng[2,4,5], M. Lee[1], M.G. Blitzer[4], B.A. Carter-Cooper[1], D. Sewell[2], I. Van Der Merwe[1], M. Imran[1], S.L. Yu[1], H. Li[1], P.C. Amrein[6], V.H. Duong[1,2], E.A. Sausville[1,2,3], A.T. Fathi[6], Z. Singh[5], M.R. Baer[1,2], S.M. Bentzen[1,7]
[1]University of Maryland Greenebaum Comprehensive Cancer Center, [2]Medicine, [3]Pharmacology, [4]Pediatrics, [5]Pathology, University of Maryland, Baltimore, [6]Massachusetts General Hospital Harvard Medical School, Boston, [7]Epidemiology and Public Health, University of Maryland, Baltimore, United States

Background: Asparaginase-induced glutamine (Gln) depletion demonstrates anti-leukemic activity in preclinical studies of AML. We hypothesized that administration of asparaginase *Erwinia chrysanthemi* (Erwinaze) would lead to effective plasma Gln reduction and may be a feasible therapeutic approach for AML, because myeloblasts may be addicted to Gln.
Aims: The primary aim was to determine the dose of Erwinaze inducing plasma Gln levels ≤120µmol/L, with an acceptable safety profile, 48 hours (h) after the first intravenous (IV) dose and before each subsequent dose administered thrice weekly for 2 weeks in patients (pts) with relapsed or refractory (R/R) AML.
Methods: This was a phase 1, single-arm, pharmacokinetic investigator-initiated trial (NCT02283190, funded by Jazz Pharmaceuticals), with a 3+3+3 design with dose de-escalation/escalation rules that incorporate both safety and biochemical activity (nadir plasma Gln levels) of IV Erwinaze. There was no intrapatient dose adjustment. For safety, a 3rd cohort of three pts was to be added if 2 of 6 pts in the 1st and 2nd cohorts experience a dose limiting toxicity (DLT) at a certain dose level. If ≥3 of 9 patients experienced DLT, the trial was to be terminated. To evaluate Gln reduction ability of Erwinaze, the dose could be increased based on 48h trough plasma Gln in cohorts of 3, 6, or 9 pts per dose level. Correlative studies measured plasma Gln, glutamate (Glu) and asparagine (Asn) levels, plasma asparaginase activity and plasma and urine 2-hydroxyglutarate (2-HG) levels.
Results: Five pts were enrolled on study. Enrollment was then halted due to Erwinaze supply manufacturing complexities. Median age was 69 (range 20-83) years, 4 were male, 2 had prior MDS or CMML, 3 had high risk abnormal karyotype, 3 had isocitrate dehydrogenase (2 *IDH1,* 1 *IDH2*) mutations, and 3 had been treated with ≥2 lines of prior treatment. Erwinaze was administered IV (25,000 IU/m^2, dose level 0) for 6 doses MWF for 2 weeks to all pts. No DLT was observed. Anemia and electrolyte abnormalities were the most common adverse events. Plasma asparaginase activity ≥0.1 IU/mL was achieved in all pts at 48h trough, but in 3 pts it decreased to zero on day 8 (72h trough). Median trough plasma Gln, Asn and peak Glu levels (µmol/L) at 48h were 27.6 (range <12.5-227), 0 (range 0-0), and 704 (range 474-754), respectively. Asn remained undetectable for the entire 2 weeks. Gln levels increased significantly on day 8 (72h trough) compared to day 5, p<0.001. Four of 5 pts (80%, lower limit of 1-sided 95% CI: 34%) achieved at least one nadir Gln value <120 µmol/L. The fold reduction (FR) in Gln level at 3 days, relative to baseline, was 0.16 (p<0.001 for rejecting FR=1). One pt achieved partial remission (PR) and one achieved hematologic improvement (HI) after 6 doses of single agent Erwinaze. Both pts had plasma Gln levels <85 µmol/L on days 5, 10 and 12. Off study, after completion of Erwinaze, they have been treated with azacitidine. Both pts are still alive in complete remission (CR) and CR with incomplete count recovery (CRi) 13.3 and 13.4 months after the on-study date. Plasma and urine 2-HG levels did not change significantly. The 3 pts with *IDH* mutations tended to have higher plasma 2-HG levels (p=0.10).

Summary/Conclusions: To the best of our knowledge, this is the first clinical report demonstrating that an asparaginase product is capable of not only decreasing plasma Gln level to ≤120µmol/L but also depleting it to undetectable (*i.e.* <12.5µmol/L) levels in pts with AML. Two of 5 patients with R/R AML had clinical responses and are alive in remission. Given clinical activity of asparaginase in AML, we are to investigate mechanistically-designed asparaginase combination therapies.

E948

PROGNOSTIC SIGNIFICANCE OF SOX2, SOX3, SOX11, SOX14 AND SOX18 GENE EXPRESSION IN DE NOVO ACUTE MYELOID LEUKEMIA (AML) PATIENTS

N. Tosic[1,*], M. Virijevic[2], I. Petrovic[3], N. Kovacevic Grujicic[3], S. Davidovic[3], N. Suvajdzic Vukovic[2], S. Pavlovic[1], M. Stevanovic[3]
[1]Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, [2]Clinic of Hematology Clinical Centre of Serbia, University of Belgrade Faculty of Medicine, [3]Laboratory for Human Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, Belgrade, Serbia

Background: Members of the SOX (SRY-related high mobility group (HMG) box) gene family encode a group of transcriptional factors with important functions in embryonic development. Also, *SOX* genes are aberrantly expressed in different types of cancer. However, their role in hematological malignancies, especially in acute myeloid leukemia (AML), remains elusive.
Aims: The aim of this study was to investigate the expression level of *SOX2*, *SOX3*, *SOX11*, *SOX14* and *SOX18* genes in *de novo* AML patients, and to evaluate their potential as prognostic markers.
Methods: Fresh bone marrow (BM) samples were collected from 50 non-APL AML patients at diagnosis (27 male, 23 female, median age 52.5 years, range 22-73) and from 8 healthy donors. Relative quantification analysis of *SOX* genes expression level was performed by RQ-PCR methodology, with *GAPDH* gene as endogenous control, and using comparative *ddCt* method with healthy controls as calibrator.
Results: The median expression level of *SOX2*, *SOX3*, *SOX11*, *SOX14* and *SOX18* in AML patients was 0.46 (0.01-226.13), 0.81 (0.01-1210.00), 0.35 (0.01-177.29), 0.98 (0.02-469.51) and 3.53 (0.18-332.00), respectively. This was not significantly different from the levels detected in healthy controls where the expression levels were 1.01 (0.32-2.54), 1.00 (0.45-5.73), 1.00 (0.19-2.83), 1.04 (0.38-2.38) and1.00 (0.48-12.29), respectively. As a cut-off value above which the patients were considered to be positive for *SOX2/3/11/14/18* gene expression we used median expression level of each *SOX* gene in healthy controls + 2SD. The percentage of patients who were positive for the expression of the studied genes ranged from 14% ($SOX2^+$ and $SOX11^+$), 20% ($SOX3^+$ and $SOX18^+$) to 28% ($SOX14^+$). A significant association with the presence of *FLT3-ITD* and *NPM1* mutations was detected in all but $SOX14^+$ patients. The same result was found concerning association with higher leukocyte count. There were no significant associations with any other presenting clinical parameters. As for the impact that SOX expression positive status that any of the analyzed genes had on the prognosis and outcome of the disease, we detected higher relapse rate in $SOX14^+$ patients (p=0.045). Significantly shorter disease-free-survival (DFS) was detected among $SOX2^+$, $SOX11^+$ and $SOX18^+$ patients (p<0.001; p=0.001; p=0.017, respectively). Although all of the SOX^+ patients had shorter overall survival (OS) time compared to SOX^- patients, the most prominent influence has been detected for the $SOX2^+$ patients (p=0.034).
Summary/Conclusions: This is the first study focused on examining the expression level of *SOX2/3/11/14/18* in AML patients. We have found that these genes are seldom overexpressed among patients in comparison with normal BM. However, in some patients, the expression of these genes is highly increased, and associated with a negative prognostic factors such as the presence of FLT3-ITD mutations and higher leukocyte count. Also, increased expression of these genes has been clearly associated with shorter DFS and OS. Although the exact function of these genes in the pathogenesis of AML is not yet known, our preliminary results show that their overexpression can have prominent prognostic significance in AML patients and therefore should be the subject of further investigation.

E949

ACUTE ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

O. Pasvolsky[1,*], O. morelli[1], U. rozovski[1], M. vaturi[1], O. wolach[1], I. amitai[1], I. vaxman[1], R. ratzon[1], M. yeshurun[1], Z. Iakobishvilli[1], R. kornowski[1], P. raanani[1]
[1]Beilinson Hospital, Petach Tikva, Israel

Background: Chemotherapeutic agents are associated with a wide range of cardiotoxic adverse effects. Anthracyclines and related drugs are some of the most implicated agents, with a well-recognized potential for the development of cardiomyopathy and heart failure. Chronic anthracycline induced cardiotoxicity can lead to cardiomyopathy, which may develop several years after treatment. Acute and subacute anthracycline induced cardiotoxicity is considered relatively uncommon, described mostly in patients treated for solid tumors or lymphomas. While anthracycline based regimens have been used to induce remission in newly diagnosed patients with acute myeloid leukemia (AML) for more than four decades, relatively little is known about the acute cardiotoxic effect of anthracyclines in this setting. Since many of these patients are candidates for hematopoietic stem cell transplantation (HSCT), an intensive intervention usually reserved for fit patients, even transient decrease in cardiac function might render them ineligible for this intervention, or might increase their transplant related morbidity.
Aims: To study the short-term outcomes of anthracycline exposure on cardiac function in patients with AML who are candidates for allogeneic HSCT. Because current AML-induction regimens use anthracyclines (most commonly daunorubicin) at a relatively high dose between 45 and 90mg/m^2/day for three consecutive days, we hypothesized that the incidence of post-induction cardiac injury in patients with AML might be high.
Methods: The medical records of 55 consecutive patients who had received induction chemotherapy and had undergone HSCT in our medical center were reviewed. Patients included in the study were those with echocardiographic data both prior to and post induction therapy. Median age at diagnosis was 59 years (range: 18-73) and 49% were males. Approximately half of the patients had *de novo* AML (N=29, 53%). 26 patients (47%) had either therapy related AML or AML secondary to a previous hematological disorder. Induction treatment included 7 days of cytarabine at a dose of 100mg/m^2/day and 3 days of daunorubicin at a dose of 45mg/m^2/day (N=2, 3.6%), 60mg/m^2/day (N=34, 61.8%) or 90mg/m^2/day (N=15, 27.3%).
Results: Selected patient characteristics are summarized in Table1. Post-induction echocardiogram studies demonstrated a significant cardiac deterioration in left ventricular ejection fraction (EF) (defined as 10% or more absolute decrease from baseline EF) in 25.5% of the patients (N=14). Higher doses (90mg/m^2/day) of anthracyclines were associated with higher rates of cardiac function deterioration (odds ratio: 4.1, 95%, confidence Interval: 1.06 to 15.7). Patients with cardiovascular risk factors and male patients tended to develop cardiotoxicity at higher rates, whereas age, white blood cell counts at diagnosis and AML type (*de novo vs.* secondary) had no impact on cardiotoxicity. The decrease in cardiac function was temporary in 10.9% of the patients (N=6) with subsequent normalization of left ventricular EF in those patients.

Table 1.

Table1. Patient characteristics

Demographics	Total		N=55
	Age, years		59 (range 18-37)
	Gender	Male	N=28 (51%)
		Female	N=27 (49%)
Cardiovascular risk factors	Any		36 (69.2%)
	HTN		21 (38.2%)
	DM		12(21.8%)
	Hyperlipidemia		24(43.6%)
	Smoker		12 (21.8%)
Cardiovascular disease	Any		10 (19.2%)
	CVA/TIA		1 (1.8%)
	PVD		2 (3.6%)
	AFib		2 (3.6%)
	s/p MI		3 (5.5%)
	s/p CABG or PCI		4 (7.3%)
	Valvular disease		2 (3.6%)
	s/p valcular surgery		1 (1.8%)
	Arrhythmia		2 (3.6%)
Cardiac parameters at baseline	LVEF (%)		60 (range 45-67)
	LVEDD (mm)		45 (range 37-55)
	LVESD (mm)		28 (range 19-42)
hematological parameters	WBC count		10K (range 0.95-169.9)
	De-novo leukemia		29 (52.7%)
	Secondary leukemia		26 (47.3%)
Anthracycline dose	90mg/m2/day		15 (27.3%)
	60 mg/m2/day		34 (61.8%)
	45 mg/m2/day		2 (3.6%)
	salvage chemotherapy		27 (49.1%)
EF change post induction	No change		38 (69.1%)
	Temporary decrease		6 (10.9%)
	Permanent decrease		8 (14.5%)

Summary/Conclusions: The use of daunorubicin at a dose of 60mg/m^2/day or less is associated with significantly lower rates of acute cardiotoxicity. Our findings should be taken into consideration when choosing the anthracycline dose, particularly in male patients with cardiovascular risk factors who are candidates for HSCT.

E950

AN INTEGER WEIGHTED GENOMIC MUTATION SCORING (IWGMS) USING THE TRUSIGHT MYELOID SEQUENCING PANEL SHOWS HIGHER MORTALITY IN PATIENTS WITH INTERMEDIATE RISK ACUTE MYELOID LEUKEMIA- A RETROSPECTIVE STUDY

Q. Qin[1,*], X. Nan[1], C. Gentille Sanchez[1], M. Greenwood[2], Y. Xing[3], A. Zieske[2], I. Ibrahim[3], K. Baker[3], L. Rice[3], B. Merritt[4], S.R. Pingali[3], R. Olsen [2], S. Iyer[3]
[1]Internal Medicine, Houston Methodist Hospital, Weill Cornell Medical College, [2]Laboratory and Genomic Medicine, Houston Methodist Hospital, [3]Hematology, Houston Methodist Cancer Center, [4]Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, United States

Background: AML is currently classified by European LeukemiaNet into favorable, unfavorable, and intermediate prognosis based on cytogenetic aberrations. Although favorable and unfavorable categories have good prognostic values, the intermediate category encompasses the majority of patients and offers unclear prognosis. The development of Cancer Genome Atlas (TCGA) opens new windows for the incorporation of next generation sequencing (NGS) into cytogenetics to enhance prognostic risk stratification. However, few studies explore the combination of cytogenetics and NGS in prognostic predictions.
Aims: Here we have developed a system of Integer Weights for the Genomic Mutation Score (IWGMS) for a quantifiable stratification of the prognostic risks associated with a combination of cytogenetic aberrations and genomic mutations. Our next step is validating the scoring system through its application to data obtained from other institutions.
Methods: Patient data at Houston Methodist Hospital was queried from Methodist Environment for Translational Enhancement and Outcomes Research (METEOR), a clinical data warehouse that integrates research databases and national registries. The diagnosis of AML was queried along with patient demographics, cytogenetics, NGS and OS. The resultant patients were divided into three categories based on their MRC cytogenetic risks- favorable, intermediate, and poor. Using the TruSight Myeloid Sequencing Panel (Illumina), mutations in 54 genes associated with myeloid disorders were tested in NGS. A scoring system was developed that assigned each of the nine TCGA mutation categories (Transcription- Factor Fusion, Nucleophosmin (NPM1), Tumor Suppressor Genes, DNA-Methylation related genes, Signaling Genes, Chromatin Modifying Genes, Myeloid Transcription Factor Genes, Cohesion complex Genes and Spliceosome-complex genes) a score between -2 (good risk) and +2 (poor risk). The IWGMS for each patient was calculated by the sum of the individual mutation scores. A IWGMS score greater than 3 was considered significant as a poor prognostic factor. Statistical analysis was done using Chi-Square, Mann Whitney U test and multivariate logistic regression analysis. Data from other institutions will be analyzed in a similar fashion for the confirmatory portion of the project.
Results: A hundred of the 1200 AML patients met the criteria for having both cytogenetic and NGS data availability. The two-year mortality rates were 43%, 52%, and 51% respectively for the favorable, intermediate, and poor cytogenetic groups. In the intermediate cytogenetic group, high IWGMS score (>3) was associated with higher mortality when compared to low IWGMS score (80% *vs* 44%, p=0.045, Fig 1). A look at the gene mutation distribution in the intermediate risk cytogenetic group also showed a general correlation between known favorable gene mutations with low IWGMS scores and unfavorable ones with high IWGMS scores. We thus hypothesize the IWGMS scoring system can be utilized to divide the intermediate cytogenetic group into higher and lower mortality subgroups based on a combination of cytogenetic and genetic mutations. We expect similar results with data from other institutions.

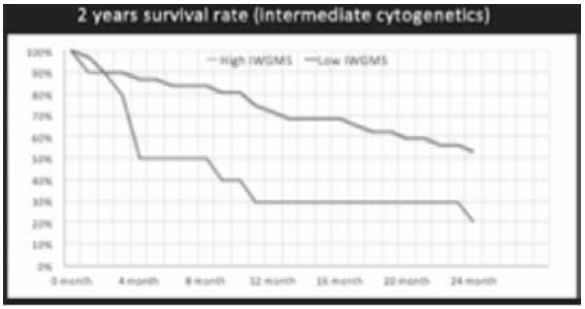

Figure 1.

Summary/Conclusions: Most studies in current literature focuses on the individual contributions of cytogenetic aberrations or genetic mutations to risk stratification and treatments risk stratification and treatment response. However, prognosis varies widely in the heterogeneous, intermediate cytogenetic class, where 60% of the AML patients belongs. We propose a systematic approach that integrates cytogenetics with genetic mutations in stratifying prognostic outcomes with a focus on the intermediate cytogenetics group. The ability to differentiate in this specific group opens great potentials for targeted therapies and improving outcomes.

Aggressive Non-Hodgkin lymphoma - Clinical

E951

SUCCESSFUL IDENTIFICATION OF SPECIFIC AMINO ACID-DEPENDENCE IN ADULT T-CELL LEUKEMIA / LYMPHOMA (ATL) AND PRECLINICAL APPLICATION FOR NEW THERAPY

T. Ishigaki[1,2,*], S. Yamazaki[3], Y. Taya[1], K. Uchimaru[4], A. Tojo[5], H. Nakauchi[1,6]
[1]Division of Stem Cell Therapy, [2]Department of Laboratory Medicine, Research Hospital, [3]Project Division of Advanced Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, [4]Laboratory of Tumor Cell Biology, The University of Tokyo, [5]Department of Hematology and Oncology, Research Hospital, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, [6]Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, California, United States

Background: Adult T-cell leukemia / lymphoma (ATL) is highly aggressive malignancy caused by human T-cell leukemia virus type 1 (HTLV-1). As leukemia/lymphoma cells are often resistant to combination chemotherapy and recent antibody therapy, new strategies should be developed. Our laboratory recently found that proliferation and survival of hematopoietic stem cells are critically dependent on the amino acid valine (Science, 2016).
Aims: We here aimed to assess amino acid-dependence of lymphoma and leukemic stem cells, and tried to establish a novel therapy by utilizing the differences in amino acid-dependence between normal and leukemic stem cells.
Methods: First, primary ATL cells were sorted from samples of 7 typical acute-type ATL patients by 12-color flow cytometry, and serially passaged on stromal cells. Then passageable ATL cells from 3 patients were transduced with GFP-expressing lentivirus for tracking and counting by image cytometry. Using complete medium and twenty different culture media each lacking a single amino acid, we examined amino acid dependency of ATL cells. Amino acids vital for ATL cells were screened by co-culture with stromal cells. Effects of these media on normal lymphocytes of healthy volunteers were also examined. Finally, the effectiveness of amino acid restriction was evaluated *in vivo* by xeno-transplantation of ATL cells into NOG mice. Mice were fed with different diets lacking specific amino acids at 6 weeks after transplantation, and sacrificed at 10 weeks for analysis of peripheral blood, organs, and lymphoma size.
Results: *In vitro* studies revealed that ATL cells have dependency on specific amino acids: cysteine, methionine, and valine. As 2-weeks restriction of the former two amino acids damaged stromal cells or normal lymphocytes, valine was picked up for further analysis. Proliferation of ATL cells was dramatically inhibited by valine restriction while the influence on normal cells was limited. Interestingly, valine restriction did not effect a significant change in the proportion of normal CD4+ populations, such as Treg, naïve, central memory, effector memory, and effector T-cells. Moreover, 4-week restriction of valine succeeded in eradicating ATL cells *in vitro* and no recurrence was observed after refilling valine although 2-weeks restriction was insufficient for extermination. In-vivo model also showed that 4-weeks restriction of valine could dramatically reduce ATL tumor size. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically.
Summary/Conclusions: We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on valine. ATL cells could be eradicated by 4-weeks of valine in vitro. In-vivo model also showed that the growth of ATL cells was significantly inhibited by dietary restriction of valine. Massive lymphoma cells, which are known to be resistant to antibody therapy, were also vulnerable to the valine restriction. There were no severe complications such as anemia, thrombocytopenia, and organ damages which are often seen in chemotherapy recipients. These data demonstrate that valine restriction may potentially provide a new option for leukemia/lymphoma therapy.

E952

VEGF AND VEGFR2 POLYMORPHISMS ARE INVOLVED IN AGGRESSIVENESS AND PROGNOSIS OF DIFFUSE LARGE B-CELL LYMPHOMA

A. Borsarelli Carvalho Brito[1,*], M. Torresan Delamain[2], C. Antonio de Souza[2], J. Vassallo[3], C. Silvia Passos Lima[1]
[1]Department of Internal Medicine, [2]Haematology and Haemotherapy Centre, [3]Laboratory of Molecular and Investigative Pathology, University of Campinas, Campinas, Brazil

Background: Angiogenesis (AG), with participation of the vascular endothelial growth factor (VEGF) and its receptor (VEGFR2), plays a key role in clinical features and outcome of patients with diffuse large B cell lymphoma (DLBCL). The ability to induce AG is variable in humans, once that *VEGF* and *VEGFR2* genes have several single nucleotide polymorphisms (SNPs) described with distinct proteins production. The wild-type alleles of *VEGF* -2578 C/A (rs699947), -2489C/T (rs1005230), -1154G/A (rs1570360), -634G/C (rs2010963), -460C/T (rs833061), 936C/T (rs3025039), and *VEGFR2* -271G/A (7667298) and -604T/C (rs2071559) SNPs determine higher production, transcriptional activity or binding efficiency of VEGF/VEGFR2.

Aims: Since the roles of these SNPs in clinical aspects, response to therapy and prognosis of DLBCL treated with R-CHOP- are still unknown, these were the aims of the present study.
Methods: Our analysis included 168 consecutive DLBCL patients at diagnosis seen at University Hospital from July 2009 to September 2014. Genotypes were identified in DNA of peripheral blood by real-time polymerase chain reaction, using a Taqman SNP Genotyping Assay. Replicates were performed in 10% of the reactions, achieving 100% of concordance. Chi-Square test, Fisher's Exact test, and multivariate analysis, using the logistic regression model, served to assess associations between genotypes and clinical aspects. Kaplan-Meier analysis was used to evaluate the effect of clinical features and genotypes on the cumulative probability of event free survival (EFS) and overall survival (OS). EFS and OS were calculated from the date of diagnosis to first event date (relapse, progression or death by disease) or last seen date and death by any cause or last seen date, respectively. The Cox proportional hazards regression model was used to evaluate the effects of clinical features and genotypes of the above mentioned SNPs on PFS and OS, and the results of analysis were presented as hazard ratios (HRs) with their corresponding 95% confidence intervals (CIs). First, these associations were examined using univariate Cox proportional hazards regression. In a second step, all variables with $P<0.10$ were included in a multivariate Cox regression. All reported P values were two-sided, and $P<0.05$ was considered to indicate statistical significance.
Results: Concerning clinical features, the frequency of the wild-types *VEGF* -1154G allele and *VEGF* -634GG genotype were more common in stage III or IV patients. The wild-type *VEGFR2* -604TT genotype was more common in high intermediate and high international prognostic index (IPI) patients. Concerning response rate, patients with the wild-type *VEGF* 936CC genotype was associated with higher complete response (CR). These patients had 2.65 more chances of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58.8% and 66.0%, respectively. At 60 months of follow-up, patients with the variant *VEGF* 1154 A and 936 T alleles had 1.52 and 1.82 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the *VEGF* 1154 G/A SNP was associated with PFS and OS: patients with the variant *VEGF* 1154 A allele had 1.88 and 1.83 more chances of having an event.
Summary/Conclusions: Our data present, for the first time, preliminary evidence that inherited abnormalities in AG pathway, related to the *VEGF* -1154G/A, -634GG and 936C/T, and *VEGFR2* -604T/C, influence clinical features, response to R-CHOP and outcome of DLBCL patients.

E953

BONE MARROW BIOPSY SUPERIORITY OVER PET/CT IN PREDICTING PROGRESSION FREE SURVIVAL IN A HOMOGENOUSLY-TREATED COHORT OF DIFFUSE LARGE B-CELL LYMPHOMA

T.H. Chen Liang[1,*], T. Martín-Santos[2], A. Jerez[1], G. Rodriguez-García[3], L. Senent[4], C. Martínez-Millán[5], B. Muiña[6], M.T. Orero[7], A. Teruel[8], A. Martín[9], J. Gómez-Espuch[10], K. Background: Recently, several studies have reported uneven results when evaluating the role of bone marrow biopsy (BMB) and PET/CT in the staging of diffuse large B cell lymphoma (DLBCL). The retrospective nature of the studies and the heterogeneity of the inclusion criteria might explain part of these discrepancies. Given the lack of a "gold-standard" to examine the most accurate test to assess BM involvement (BMI) at diagnosis, the prognostic value of each technique emerges as a key factor to determine the correct management at baseline.
Aims: The main aim of this study was to evaluate the prognostic impact on progression free survival (PFS) of BMI at baseline, assessed by means of BMB or PET/CT, in DLBCL with a priority in narrowing the heterogeneous inclusion criteria used in most reports to date.
Methods: This is a retrospective multicenter study including patients older than 17 years, with a BMB and a PET/CT performed simultaneously as part of the routine pre-therapy staging for newly diagnosed DLCBL. Patients had not received either chemotherapy or corticosteroids and no concomitant malignancy was known to be present at the time of both procedures. Only patients treated with R-CHOP as first line therapeutic strategy were included. Only variables with a $p<0.150$ in univariate analysis were included in the multivariate Cox regression for outcome predictors.
Results: A total of 271 DLCBL patients were initially identified; we excluded: 31 patients who received low intensity chemotherapy regimens (R-COP, Mini-CHOP-R, monotherapy with steroids) due to advanced age, comorbidities or fragility, and 35 patients enrolled in clinical trials including standard regimens plus new agents (Bortezomib, Lenalidomide, Ibrutinib) or non-standard regimens (R-CHOP/14, Da-EPOCH-R, MACOP-B, Mega-CHOP, Hyper-CVAD)
In the homogeneously treated (R-CHOP/21) 205 DLBCL patients subset, the median age at diagnosis was 61 y.o. (range 18-85), with a balanced gender distribution (103 females/ 102 males). Twenty-six of these patients (12.7%) had BMI on BMB, whereas 43 (21%) had BMI according to PET/CT finding. Fifty-three patients (25.9%) had BMI according to either BMB or PET/CT. Concordant BMI by means of both techniques was present in 16 (7.8%) patients.
With a median follow-up of 25 months (15-47 months, p25-p75), 50 patients (24.4%) progressed or relapsed and 41 (20%) died. The 3-year estimated progression-free survival (PFS) and overall survival (OS) were 70%, and 78%, respectively. By univariate analysis, factors associated with a shorter PFS, with a $p<0.150$, were: female gender, IPI≥3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+) and BMB-BMI(+). In multivariate analysis only two factors, BMB-BMI(+) (HR: 3.27, 95%CI 1.58-6.78; p=0.001) and IPI≥3 (HR: 1.96, 95%CI 1-3.76; p=0.04) were independently associated with a shorter PFS. By univariate analysis, factors predictive of a shorter OS, with a $p<0.150$, included: IPI≥3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+). In multivariate analysis only IPI ≥3 (HR: 2.6, 95%CI 1.13-5.14; p=0.006) was independently associated with a shorter OS.
Summary/Conclusions: In our DLBCL cohort, treated with a uniform first-line chemotherapy regimen, BMI by BMB complemented IPI in predicting those patients with a higher risk for relapse or progression, while IPI defined a subset of patients with a worse survival. In this cohort, BMI by PET/CT could not independently predict a shorter PFS and/or OS.

E954

THE PROGNOSTIC SIGNIFICANCE OF CD11B+CX3CR1+ MONOCYTES IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

J.Y. Kwak[1,*], J.-A. Kim[2], H.-Y. Yhim[1], S.-H. Ko[2], Y. Park[3]
[1]Internal Medicine, Chonbuk National University Hostpital, Jeonju, [2]Internal Medicine, Catholic University of Korea, Seoul, [3]McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Korea, Republic Of

Background: Interest in the role of myeloid-lineage cells, including monocytes and their precursors, has been increasing in prognosis of lymphoma. It has been shown that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in prognosis of DLBCL. Recent studies suggest $CD11b^+$ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of $CD11b^+CX3CR1^+$ monocytes in DLBCL patients.
Aims: The study investigates the prognostic significance of peripheral blood (PB)- and bone marrow (BM)- $CD11b^+CX3CR1^+$ monocytes on progression-free survival (PFS) and overall survival (OS) in newly diagnosed DLBCL patients treated with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy.
Methods: The prospective cohort study was conducted in two Korean institutions from May 2011 to August 2015. Patients were eligible if they were newly diagnosed DLBCL, treated with R-CHOP, and provided informed consents. Percentages of $CD11b^+CX3CR1^+$ cells in total mononuclear cells (>50,000 cells) were measured by flow cytometric analysis using fresh PB and BM aspirate samples before treatment.
Results: Eighty-nine patients (male, 52) were enrolled. The median age was 65 years (range, 19-88). 37 patients (41.6%) were classified as high-intermediate (HI) or high risk according to National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI). $CD11b^+CX3CR1^+$ monocytes were detectable in all PB and BM samples analyzed. The median percentage of $CD11b^+CX3CR1^+$ cells was 3.31% (range, 0.21 to 21.66%) in PB and 3.09% (range, 0.20-20.01%) in BM. Patients were categorized into high (PB- or BM-$CD11b^+CX3CR1^+$ cells >median) and low (<= median) groups. High PB-$CD11b^+CX3CR1^+$ cell group was significantly associated with unfavorable parameters including age >=60 years, advanced stage, elevated serum LDH level, and extranodal involvement ($P<0.05$), which were clinical factors associated with higher risk NCCN-IPI ($P=0.004$). However, BM-$CD11b^+CX3CR1^+$ cells were not associated with clinical variables. With a median follow-up of

27.7 months (IQR, 14.6-46.1), low PB-CD11b$^+$CX3CR1$^+$ cell group had significantly better PFS (3-year, 77.1% *vs* 58.7%; *P*=0.006) and OS (3-year, 86.6% *vs* 58.4%; *P*=0.004) than high PB group. No significant survival differences were observed between high and low BM-CD11b$^+$CX3CR1$^+$ cell groups. Univariate analyses demonstrated that age, ECOG performance status, B symptoms, extranodal involvement, NCCN-IPI, and PB-CD11b$^+$CX3CR1$^+$ cell group were significantly associated with OS. However, HI or high risk NCCN-IPI was an only independent prognostic factor for reduced OS (hazard ratio, 4.41; 95% confidence interval, 1.17-16.59) in the multivariate analysis. In subgroup analysis according to the NCCN-IPI, 3-year OS of high PB-CD11b$^+$CX3CR1$^+$ monocytes was significantly inferior to that of low group (34.0% *vs* 77.9%; *P*=0.026) in DLBCL with HI to high risk NCCN-IPI. In contrast, PB-CD11b$^+$CX3CR1$^+$ monocytes failed to predict OS (3-year, 91.7% *vs* 96.7%; *P*=0.878) in the low to low-intermediate risk NCCN-IPI subgroup.

Summary/Conclusions: Our study represents PB-CD11b$^+$CX3CR1$^+$ monocytes can be used in differentiating patients with high risk for early death and are associated with risk stratification by the NCCN-IPI, possibility of potential therapeutic target in DLBCL.

Background: Clinical management of pediatric rare non-Hodgkin lymphomas (r-NHL) (<1case/1million) is unclear.

Aims: To characterize children with r-NHLs in AIEOP centers. Performing a retrospective analysis of r-NHLs AIEOP case records, describing main epidemiologic, clinical and histopathological parameters. To review the histopathological case records according to WHO 2008 classification. Evaluation of treatment response - chemotherapy or *wait and see* (W&S) in terms of overall survival (OS) and of complete remission (CR), relapse and resistance cases, secondary neoplasias and deaths.

Methods: Data from the AIEOP database were collected between 1997 and 2015.

Results: The incidence of r-NHL in AIEOP registry was 6.5% (67 pts). Forty-eight were male and 19 female, median age was 11 years (0.3-21 years). Classification according to St.Jude stage was: stage I n=36; II n=13; III n=11; IV n=7. Bone marrow (BM) involvement was diagnosed in 7 cases; central nervous system (CNS) in one case. Patients who presented LDH >500 UI were 18. B-rNHLs accounted for approximately 49% (33 pts) of the entire population analysed, T-rNHLs for another 40% (27 pts), the remaining 11% (7 pts) of the population under study being categorized as "*others*" (other than those deriving from B or T/NK-cells). The most common histological subtypes were: follicular lymphoma (FL) amongst B-rNHLs; peripheral T-cell lymphoma (PTCL) n.o.s., mycosis fungoides (MF), subcutaneous panniculitis T-cell lymphoma (SPTCL) and lymphomatoid papulosis (LP) amongst T-rNHLs; histiocytic sarcoma (HS) amongst "*others*" category. A similar proportion for both B and T/NK NHL underwent either W&S approach only or active treatment (AT): 45% and 55% were W&S and AT approach, respectively. Patients in "*others*" category were almost actively treated (71%). Therapy was based on AIEOP B-, T/NK-NHLs and ALCL protocols +/- RT, and/or immunotherapy. Surgical resection has been performed in case of localized disease B-rNHLs only, followed by a W&S strategy, with 100% 3-yr OS. It has been seen that B-rNHLs have a more favorable prognosis and very few events (development of resistance to therapy, relapse, secondary malignancy, death). Amongst T/NK rNHLs-related events, death remained the most likely to occur, differently than B-rNHLs which showed a slight prevalence of relapses; as for the category "*others*", no relative preponderance has been registered for any of the above-mentioned events. The 3-year OS has shown to be significantly higher for B-rNHLs than for T/NK-NHL (94% *vs* 69%, p-value 0.024), as illustrated in *Figure 1*. Regarding the treatment, the 3-year OS was 100% for the patients underwent a W&S approach whereas 75% for treated patients (p-value 0.037). FLs show favourable clinical course and outcome, limited stage at diagnosis. Differently from adults, pFLs have a higher 3-years OS with respect to that of other histological pediatric NHLs subtypes (100% *vs* 75%, p-value 0.049).

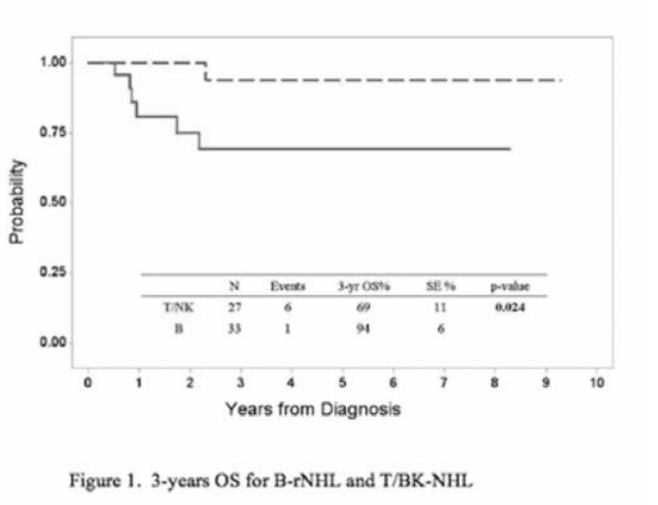

Figure 1. 3-years OS for B-rNHL and T/BK-NHL

Figure 1.

Summary/Conclusions: The incidence of AIEOP pediatric rNHLs is in line with the literature. In case of localized disease, a W&S approach was successfully applied; of these, the T/NK rNHLs being most often registered and with best prognosis are the cutaneous lymphomas (*i.e.* LyP, MF). Patients' prognosis varies greatly depending on the histological subtype. The better survival was observed in the B-rNHLs compared to other categories. An international collaboration is warranted, in order to create new guidelines or protocols for an appropriate management of pediatric rNHLs.

E956

PRIMARY ANALYSIS OF THE EFFECT OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF 110 CASES OF T CELL LYMPHOMA

C. Li[1,2,*], D. Yang[1], X. Chen[1], J. Chen[1], T. Wang[1], Q. Zou[1], C. Gu[1], D. Wu[1,2]

[1]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [2]Institute of Blood and Marrow Transplantation,Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: T cell lymphoma(T-NHL) is a rare and heterogeneous group of lymphoid malignancies with mostly poor outcome with conventional treatment.Recent studies have suggested that Hematopoietic stem cell transplantation(HSCT) has a better curative effect and is superior to traditional chemotherapy.

Aims: To investigate the effect of HSCT in the treatment of T cell lymphoma.

Methods: The clinical data of 110 patients with T cell lymphoma treated by HSCT from January 2006 to August 2016 in our center were retrospectively analyzed.

Results: (1)110 T-NHL patients, 70 males and 40 females, aged 7-64 years (median age 26 years). Disease subtypes: 35 cases of T-cell lymphoblastic lymphoma(T-LBL), 23 cases of NK / T cell lymphoma(NK/TCL), 24 cases of peripheral T-cell lymphoma (PTCL, NOS), 24 cases of variable large cell lymphoma (ALCL), 3 cases of subcutaneous panniculitic T cell lymphoma(SPTCL) and 1case of hepatosplenic T cell lymphoma(HSTCL).Transplantation type: 56 cases of autologous hematopoietic stem cell transplantation (auto-HSCT), 54 cases of allogeneic hematopoietic stem cell transplantation (allo-HSCT). The follow-up was ended in December 2016, the duration of following-up ranged from 2 to 130 months (median follow-up time was 22 months). (2)56/110 patients with auto-HSCT, 3 year overall survival (OS) and disease-free survival (EFS) were 76.5% and 60.9%, respectively. (3)54/110 patients with allo-HSCT, 3 year EFS and OS of allo-HSCT were 61.7% and 58.9%, respectively. (4)36/56 patients with CR1 status before auto-HSCT, 3 year OS and EFS were 87.3% and 68.7% respectively. 20/56 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 60.6% and 40.2%. The OS and EFS of the two groups were significantly different (P=0.001).(5)45/110 cases were young and high-risk patients (age<60 years, IPI score ≥3).25/54 cases treated with allo-HSCT, the 3 year OS and EFS were 62.8% and 60.8%. 20/56 cases treated with auto-HSCT, the 3 year OS and EFS were 47.6% and 36.9%. The OS and EFS of the two groups were also significantly different (P=0.001).

Summary/Conclusions: HSCT can improve the efficacy of T cell lymphoma. Auto-HSCT in first complete remission (CR1) enables T-NHL patients with

greater benefit. Allo-HSCT can cure some T-NHL patients, which can be considered for the treatment of young and high-risk T-NHL patients.

E957

SHORT COURSE OF R-HYPERCVAD/MTX/ARA-C FOLLOWED BY ASCT AS FIRST-LINE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS PROLONGS PROGRESSION FREE SURVIVAL TO MORE THAN 9 YEARS. SINGLE CENTER EXPERIENCE

M. Andrade-Campos[1,2,*], S. Mercadal[1], E. Domingo Domenech[1], V. Paredes Henao[1], C. Aguilera Gomez[1], A. Oliveira Ramos[1], E. de la Banda[3], F. Climent[3], R. Parody Porras[1], A. Fernandez de Sevilla[1,4], A. Sureda[1], E. Gonzalez Barca[1,4]
[1]Department of Hematology, Institut Català d'Oncologia Hospitalet, IDIBELL, Barcelona, [2]CIBER de Enfermedades Raras, CIBERER, IISCIII, Zaragoza, [3]Pathology Department, Hospital Universitario de Bellvitge, IDIBELL, [4]Departament of Clinical Sciences, University of Barcelona, Barcelona, Spain

Background: Mantle cell lymphoma (MCL) is considered an incurable disease with an historical median overall survival around 3-4 years with short progression free survival (PFS) periods. Regimens that include high dose cytarabine and consolidation with autologous stem cell transplant (ASCT) have become standard therapy for fit patients. The median PFS reported after 4-6 cycles HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD without ASCT consolidation, achieving the same median PFS of 4.6 years (Romaguera et al, Br J Hematol 2010). Based on this we have review our experience using a short course of HyperCVAD followed by transplant consolidation.
Aims: To analyze our experience treating fit patients with MCL in first line with a short course of 2 cycles of R-HyperCVAD followed by consolidation with ASCT.
Methods: from January 2002 to August 2016, the patients diagnosed with MCL treated in first line with a short course of 2 cycles of R-HyperCVAD and ASCT were included in this retrospective analysis. International working group response assessment criteria were used, PFS was calculated from the date of start therapy until date of relapse/progression or last contact.
Results: During the study period 85 MCL patients were registered: 7 (8.2%) did not receive immediate therapy, 44 (52.4%) were not eligible for intensive therapy due to comorbidities or age and 33 (39.3%) were treated with R-HyperCVAD. Clinical characteristics at diagnosis of these 33 patients were: M/F ratio: 26/7 (78.8%/21.2%), median age: 63 y.o (limits: 40-73), ECOG 0-1: 26 (86.7%), Ann Arbor stage III-IV 28/31 (90.3%), MIPI score: low risk: 5 (16.7%), intermediate risk: 17 (56.7%), high risk: 8 (26.7%). Thirty (90.9%) patients completed the 2 cycles of R-HyperCVAD. Reasons for discontinuation were: 2 deaths for sepsis and 1 CNS progression. Intention to treat response rate was: CR 26 (78.8%), PR 2, (6.0%), progressive disease 3 (9.0%), not evaluable 2 (6.0%). Among the 28 patients in CR / PR considered eligible for consolidation with ASCT, 8 patients were not transplanted: 4 (14.3%) had harvest failure (all before plerixafor availability), 2 had persistent toxicity (prolonged neutropenia and severe mucositis) and were not longer considered for ASCT, 1 rejected, 1 unknown cause. Conditioning regimen was BEAM/LACE in 18 (90%) patients and cyclophosphamide-TBI in 2 (10%). One patient died 10 days after infusion for sepsis. With a median follow-up of 35 (1-131) months, the median PFS was 73.0 (95%IC 38.2-107.8) months (6.08 years) for the whole group, 114 (47.3-180.7) months (9.4 years) for the transplanted patients *vs* 21 (3.1-38.9) months (1.8 years) for the not transplanted group. The median OS was 123 (31.9-214.1) months, median OS was not reached for transplanted group *vs* 31.0 (7.5-54.6) months for not transplanted.

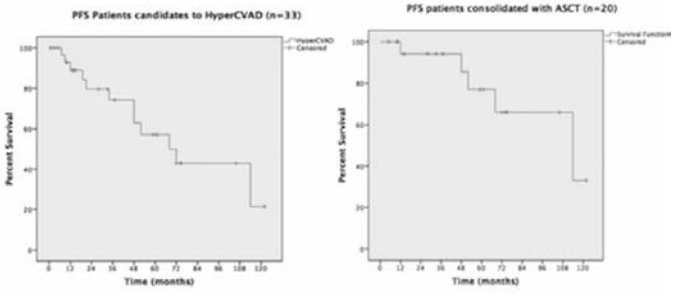

Figure 1.

Summary/Conclusions: A short course of R-HyperCVAD achieves a very high remission rate in fit patients with MCL. Stem cells could not be obtained in a small proportion of patients, all of them before the use of plerixafor. Two thirds of the patients could complete the planned therapy with ASCT consolidation, and those patients have an excellent outcome, with a PFS of more than 9 years.

E958

THE FREQUENCY OF INCIDENTAL MALIGNANCIES DETECTED BY PET/CT SCANS IN PATIENTS WITH LYMPHOMA AND THE ASSOCIATED CLINICAL IMPLICATIONS

J. Falconer[1,*], G. Kidson-Gerber[2], E. Wegner[2]
[1]Haematology, Concord Repatriation General Hospital, [2]Haematology, The Prince of Wales Hospital, Sydney, Australia

Background: PET/CT imaging has a well-established role in the investigation of malignant lymphoma. Given the widespread clinical applications, unexpected findings are occasionally identified. Whilst there is substantial information pertaining to additional primary cancers identified on PET/CT in patients with solid organ malignancy, there is a relative paucity of data in patients with lymphoma.
Aims: The primary aim was to identify the frequency of incidental second malignancies detected by PET/CT scans in patients with lymphoma. Qualitative data related to histological diagnosis and staging, interruptions or obstacles to lymphoma therapy, therapy for the second malignancy and the overall impact upon prognosis were also reviewed.
Methods: A total of 550 PET/CT images were performed in 298 patients at The Prince of Wales Hospital, Sydney Australia between January 2013 – March 2016. Patients with both Hodgkin's and Non-Hodgkin's lymphoma, with PET/CT imaging performed for all medicare-approved indications were included. All PET/CT reports suggestive of an incidental second malignancy prompted further review of electronic medical records, MOSAIC cancer database and paper medical records. Where a clear diagnosis of second malignancy was confirmed, information regarding histological findings and staging, as well as the implications of this diagnosis related to treatment of the underlying lymphoma and impact on overall prognosis was collected.
Results: 510 PET/CT scans in 259 patients had confirmed diagnoses of lymphoma. Patients aged 17 to 96 were included in the study, with a median age of 62 years. Of the 259 patients included (M=155; F =104), 55 patients had a diagnosis of Hodgkin's lymphoma and 204 patients a diagnosis of Non-Hodgkin's lymphoma. A total of 33 out of 259 patients with a diagnosis of malignant lymphoma had PET/CT findings suspicious for an underlying second malignancy (12.7%). Of the 33 patients, 19 underwent further invasive investigation, with a total of 8 patients having a biopsy proven histological diagnosis of a second malignancy (3.1%). Qualitative information was gathered regarding the patients who did not have further investigation.
Summary/Conclusions: The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental second malignancies were early stage and gastrointestinal in origin. Further retrospective as well as prospective data may assist in the establishment of guidelines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignancy.

E959

CLINICAL IMPACT OF KARYOTYPIC EVOLUTION ON THE PROGNOSIS OF DIFFUSE LARGE B CELL LYMPHOMA

Y. Mizuno[1,*], T. Kobayashi[1], N. Uoshima[2], E. Kawata[2], H. Uchiyama[3], Y. Chinen[1], Y. Shimura[1], S. Horiike[1], J. Kuroda[1]
[1]Hematology, Kyoto Prefectural University of Medicine, [2]Hematology, Japanese Red Cross Kyoto Daini Hospital, [3]Hematology, Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan

Background: The acquisitions of additional chromosomal abnormalities are generally accompanied by the emergence of therapeutic resistance and eventually lead to poor treatment outcome in cancers. However, the actual clinical impact of karyotypic evolution on prognosis differs depending on the type of hematologic malignancy. Although several prognostic indexes, including the International Prognostic Index (IPI), revised IPI (R-IPI), National Comprehensive Cancer Network (NCCN)-IPI, and Kyoto Prognostic Index (KPI) which we have developed (Kobayashi T. Blood Cancer J 2016), have the determinants for prognosis, little is known concerning the prognostic impact of karyotypic evolution in diffuse large B cell lymphoma (DLBCL), the most prevalent subtype of non-Hodgkin lymphoma.
Aims: We in this study investigated the clinical impact of karyotypic evolution on the treatment outcome of DLBCL.
Methods: We retrospectively examined the medical records of 465 DLBCL patients who were diagnosed and treated with either rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP) or with a R-CHOP-like regimen at three independent institutes in Kyoto, Japan, between January 2006 and April 2014. We analyzed the relationship between the number of subclones and prognosis utilizing the Kaplan-Meier curve and Cox proportional hazards regression analysis. We also utilized Fisher's exact test to investigate the correlation between the number of subclones and the conventional prognostic indexes, *i.e.* R-IPI, NCCN-IPI, and KPI. This study was conducted in accordance with the ethical principles of the Declaration of Helsinki

and was approved by the institutional review boards of all participating institutes.
Results: Among the 465 DLBCL cases, karyotypic analyses by G-banding were performed on biopsied tumor specimens before the start of treatment in 181 patients. Among the 181 patients, metaphase spreads were available for G-banding in 120 patients. Neither overall survival (OS) nor progression free survival (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, *i.e.*, patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and KPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.
Summary/Conclusions: DLBCL is a cytogenetically and molecularly heterogenous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, *i.e.*, DLBCLs with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.

E960

REGIMEN INTENSIFICATION MAY IMPROVE OUTCOMES IN PATIENTS WITH HIGHER RISK HUMAN IMMUNODEFICIENCY VIRUS (HIV) RELATED AGGRESSIVE B-CELL LYMPHOMAS

E. Wang[1,*], J. Clara[1], S. Dalia[2], B. Shah[3], C. Bello[3], P. Chervenick[3], M. Kharfan-Dabaja[4], L. Sokol[3], E. Sotomayor[5], R. Komrokji[3], J.C. Chavez[3]
[1]Department of Internal Medicine, University of South Florida Morsani College of Medicine, Tampa, [2]Hematology Oncology, Mercy Clinic Oncology and Hematology, Joplin, [3]Malignant Hematology, [4]Bone Marrow Transplant, H.Lee Moffitt Cancer Center & Research Institute, Tampa, [5]Malignant Hematology, George Washington Cancer Center, Washington D.C., United States

Background: Despite effective combination antiretroviral therapy for HIV, there remains an increased incidence of HIV related B-cell Non-Hodgkin lymphomas (NHL). The introduction of early antiviral therapy and effective chemotherapy have led to improved outcomes overall. Regimen intensification (RI) in HIV associated B-cell NHLs has shown improved survival, especially in the rituximab era (Barta et al, Blood 2013).
Aims: To examine the effect of RI on the overall survival (OS) and progression free survival (PFS) compared to CHOP based chemotherapy according standard risk stratification.
Methods: Patients with HIV associated aggressive B-cell NHL were identified between 2001- 2015 at Moffitt Cancer Center. Patients with primary central nervous system lymphoma, T-cell NHL and indolent NHLs were excluded. Patients received R-CHOP or intensive chemotherapy (IC) including DA-EPOCH, hyperCVAD or CODOX/IVAC as initial treatment. Data collected included patient demographics, disease baseline characteristics, CD4 count, HIV viral load, treatment regimen, response, and outcomes including relapse and OS. The IPI score was calculated, and patients were divided into two groups: lower risk group (low and low-intermediate IPI risk) and higher risk group (high-intermediate and high). Descriptive statistics were used for baseline characteristics. Kaplan Meier method was used to estimate PFS and OS, and the log-rank test was used to compare OS and PFS between lower and higher risk groups.
Results: A total of 83 patients were included. The M:F ratio was 9.4. Median age was 45 years (y) (range 25 – 65). Two thirds of patients were Caucasian. The median time from HIV to NHL diagnosis was 29 months (range 0 – 284). Eighty two percent presented with stage III/IV disease. Bulky disease was present in 27%, elevated LDH in 66%, and CD4 count<100/mL at diagnosis in 22% patients. Fifty percent of patients were on HAART therapy at time of lymphoma diagnosis. Chemotherapy regimens included: RCHOP (n=30, 36%), CHOP (n=12, 15%), DA-EPOCH-R (n=27, 33%), DA-EPOCH (n=1, 1%), hyperCVAD (n=11, 13%) and CODOX/IVAC (n=2, 2%). The median follow up was 2.7 y (95% CI 2.0-3.4). The median OS and PFS for the whole cohort was 5.9 and 4 y, respectively. The median OS was 4 y (95% CI 1.5-6.5) for patients who received CHOP based regimen and was not reached (NR) for patients who had IC (p=0.44). Based on the IPI, the median OS was NR for the lower risk group compared to 1.8 y in higher risk group (p=0.025). Among patients who received CHOP, the median OS for those with lower risk disease was NR compared to 1.8 y in patients with higher risk disease (p=0.07). For patients who received IC, the median OS was NR among both lower and higher risk groups (p=0.2). Among patients who received CHOP, the median PFS for those with lower risk disease was NR compared to 1 y in patients with higher risk disease (p=0.05). For patients who received IC, the median PFS was NR among lower and 1.4 y higher risk groups (p=0.34).
Summary/Conclusions: The IPI score remains prognostic in HIV related B-cell NHLs. There was a trend for improved OS and PFS using IC regimens. CHOP treatment remained associated with worse outcome among higher risk patients while IC regimens may overcome the higher risk features based on the IPI.

E961

EPSTEIN-BARR VIRUS LATENT MEMBRANE PROTEIN 1-MEDIATED OVEREXPRESSION OF MYC AND BCL2 CAN PREDICT POOR PROGNOSIS IN PATIENTS WITH EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE

J.-H. Wang[1], X.-W. Bi[2], Z.-J. Xia[1], W.-Q. Jiang[2], H.-Q. Huang[2], L. Wang[1,*]
[1]Hematologic Oncology, [2]medical oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Recently double-hit lymphoma or double protein expressor lymphoma has been identified as a distinct group of diffuse large B cell lymphoma with poor prognosis. However, the expression status, clinical and prognostic effect of combined overexpression of MYC and BCL2 in extranodal NK/T-cell lymphoma, nasal type (ENKTL) are not known.
Aims: This study aims to explore the clinical and prognostic effect of combined overexpression of MYC and BCL2 in ENKTL.

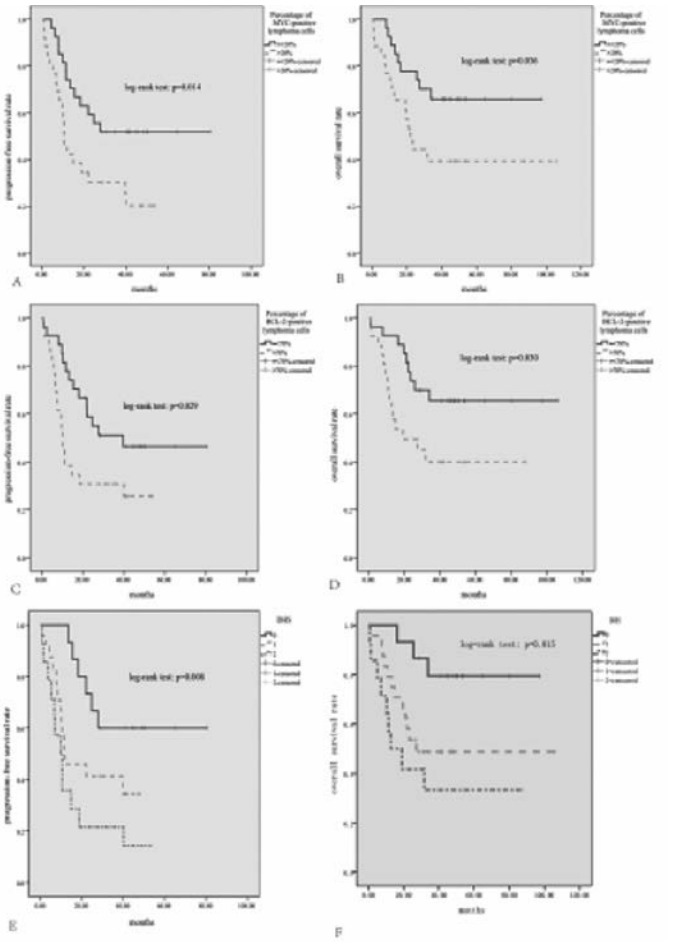

Figure 1.

Methods: Paraffin-embedded lymphoma samples from 53 patients with newly diagnosed ENKTL were studied using immunohistochemistry for MYC and BCL2, and fluorescent *in situ* hybridization (FISH) for MYC and BCL2 were done on 5 tissue sections with highest percentages of both MYC and BCL2 positive lymphoma cells.
Results: The median percentage of MYC-positive lymphoma cells and BCL2-positive lymphoma cells were 20% (range, 5% >45%) and 70% (10% >95%), respectively. Using median scores as cutoffs, we assigned each patient an IHC double-hit score (DHS) that ranged from 0 to 2. Using this DHS, 15 patients (28.3%) had a DHS of 0, 24 patients (45.3%) had a DHS of 1, and the remaining 14 patients (26.4%) had a DHS of 2. FISH analysis was performed on 5 tissue sections with DHS of 2, and none of them had MYC or BCL2 rearrangement. The DHS was not associated with patients' age, gender, disease stage, LDH level, B symptoms, performance status, or local tumor invasiveness. However,

patients with tumor localized in extranasal sites seemed to have higher expression of BCL2 and higher DHS than nasal lesions (p=0.014 and 0.042, respectively). In univariate survival analysis, either high expression of MYC or BCL2 was significantly correlated with inferior PFS and OS (p<0.05). According to the DHS, patients with ENKTL could be divided into three significantly different risk groups for PFS and OS (3-year PFS rate for DHS of 0, 1, and 2 was 60%, 41%, and 21%, respectively, p=0.008; 3-year OS rate for DHS of 0, 1, and 2 was 79%, 49%, and 33%, respectively, p=0.015). In multivariate survival analysis, it was found that DHS was an independent prognostic factor for both PFS and OS (p=0.006 and 0.011, respectively).
Summary/Conclusions: Our study demonstrated that DHS can help identify patients with newly diagnosed ENKTL who are at a high risk for a poor clinical outcome, which needs to be validated in prospective clinical trials with patients treated uniformly.

E962

SOLUBLE INTERLEUKIN-2 RECEPTOR AS A PREDICTIVE MARKER FOR SPONTANEOUS REGRESSION OF OTHER IATROGENIC IMMUNODEFICIENCY-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS; A RETROSPECTIVE STUDY

Y. Nakajima[1,*], S. Fujisawa[2], C. Nigauri[2], A. Matsumura[1], T. Ando[2], T. Suzuki[2], E. Ogusa[2], Y. Ishii[2], K. Miyashita[2], H. Takahashi[1], T. Miyazaki[1], K. Motohashi[2], M. Hagihara[1], K. Matsumoto[1], E. Yamazaki[3], H. Nakajima[1]
[1]Department of hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, [2]Department of Hematology, Yokohama City University Medical Center, [3]Clinical Laboratory Department, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: Patients treated with immunosuppressive drugs (ISD) for autoimmune diseases are at an increased risk of developing other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OI-LPD). Some patients with OI-LPD shows spontaneous regression after withdrawal of ISD, but some requires chemotherapy. The factors that are associated with spontaneous regression and outcomes of chemotherapy remain uncertain.
Aims: The aims of our retrospective study are to assess the clinical factors that predict spontaneous regression of lymphoma after ISD withdrawal in patients with OI-LPD and to evaluate the outcomes of patients who underwent chemotherapy without spontaneous regression.
Methods: We collected data from all patients with autoimmune disease who were pathologically diagnosed with OI-LPD between January 2002 to October 2016 at Yokohama City University Hospital, and Yokohama City University Medical Center.

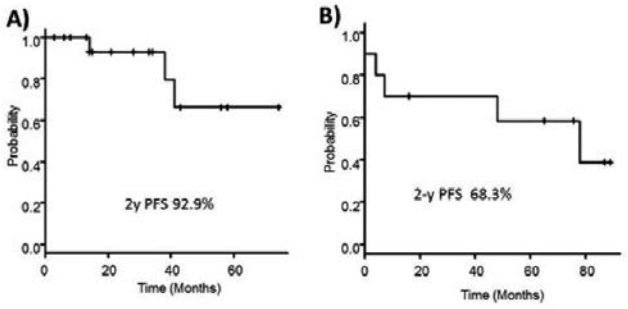

Figure 1. Kaplan–Meier curves for progression-free survival (PFS) (A) in patients with spontaneous regression, and (B) in patients with DLBCL without spontaneous regression treated with CHOP/CHOP-like ± rituximab. (B), PFS is defined as the time from the first day of chemotherapy to progression.

Figure 1.

Results: The patients included 12 males and 28 females, with a median age at diagnosis of 65 years (range 30-81). Methotrexate (MTX) was administered to all patients at any point of the clinical course before OI-LPD. The median time from diagnosis of autoimmune disease to OI-LPD development, and the median duration of MTX administration were 129 months (range 11-564), and 89 months (range 4-297), respectively. The histological findings of OI-LPD were diffuse large B-cell lymphoma (DLBCL) in 26 patients, follicular lymphoma in 1, MALT in 2, peripheral T cell lymphoma, not otherwise specified in 3, Hodgkin lymphoma in 4, and LPD in 4. EBER *in situ* was examined in 30 patients:17 positive, and 13 negative. The median observation period in the surviving patients was 34 months (range 3-119). The 2-year progression-free survival (PFS) and overall survival (OS) rates for all 40 patients were 69% and 79%, respectively. A total of 18 patients (45%) had spontaneous regression after ISD withdrawal. The median time from ISD withdrawal to spontaneous regression was 4 months (range 1-13). Among the 18 patients with spontaneous regression, 3 relapsed. Of the 22 patients without spontaneous regression, 20 subsequently underwent chemotherapy: 18 underwent CHOP/CHOP-like ± rituximab, and 2 underwent other regimens. In total, 7 patients died: all died from lymphoma progression. Compared to those without spontaneous regression, patients with spontaneous regression had clinical stages I-II (*P*=0.021), performance status of 1-2 (*P*=0.028), normal levels of LDH (*P*=0.026), and lower levels of sIL-2R (*P*=0.005). The ROC curve analysis showed the appropriate cut-off of sIL-2R levels to be 2400 U/mL for predicting spontaneous regression (AUC, 0.74; sensitivity, 0.81; specificity, 0.67). On multivariate analysis, only an sIL-2R level of <2400 U/mL was associated with spontaneous regression (odds ratio, 0.03; 95% CI, 0.002-0.39; *P*=0.007). Thirteen patients with DLBCL who did not have spontaneous regression received CHOP/ CHOP like ± R therapy. The CR rates, and 2-year PFS and OS of these 13 patients were 38%, 68.3%, and 82.1%, respectively.
Summary/Conclusions: Our study revealed that an sIL-2R level of <2,400 U/mL was significantly associated with spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.

E963

PROGRAMMED DEATH-1 PROTEIN EXPRESSION AND ITS RELATION WITH HISTOLOGIC AND CLINICAL VARIABLES IN MYCOSIS FUNGOIDES

C. Vasquez[1], S. Novelli[2,*], A. Mozos[1], P. Garcia Muret[3], A.C. Caballero[2], J. Sierra[2], J. Briones[2]
[1]Pathology, [2]Hematology, [3]Dermatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Mycosis fungoides (MF) is a T-cell malignancy with affinity for the skin. In early stages,treatment directed to the skin can induce long-lasting remissions. However, advanced stages are characterized by short-duration remissions and progressive disease. The programmed death cell surface protein-1 (PD-1) is expressed on activated T cells. Interactions between PD-1 and its ligands control the induction and maintenance of peripheral T-cell tolerance during the normal immune response. These interactions may also play a role in the immune evasion of tumors in which PD-1 ligand is overexpressed.
Aims: To described histologic characteristics and the proportion and intensity of PD1 expression by tumor cells, as well as the presence of PD1 positive lymphocytes in the epidermis in patients with MF. To identify histologic variables that might have an impact in clinical outcome.

Table 1.

Characteristics of Patients	Frequency	Percentage
Age (<60 vs. ≥60 years old)	< 60 years old: n= 37	57 %
Gender	Male n= 39	60 %
Stage	Early Stage n=52; Advanced Stage n= 13	80 %/20%
Intensity of PD1 in positive cells	No intensity n= 5	8 %
	+1 n= 30; +2 n=19; +3 n=11	46 %/29%/17%
Tumoral cell expressing PD1	<60% n= 40; ≥60% n= 25	62%/39%
Presence of mitosis in PD1+ cells	Positive n= 4	6%
	Negative n=61	94%
Intraepidermal PD1+ cells	No cells n= 32	49%
	+1 n=25; +2 n =8	39%/12%
Intensity of tumoral infiltrate	+1 n=18; +2 n=33;+3 n=13 ; +4 n=1	28%/51%/20 %/1%
Epidermotropism of tumoral cells	+1 n= 24; +2 n=22; +3 n=19	37%/34%/29 %
Degree of atypia	+1 n= 38; +2 n= 23; +3 n= 4	59 %/35%/6%
Accompanying non tumoral cellularity	+1 n=42; +2 n=19 ; +3 n= 4	65%/29%/6%
Loss of CD7 expression	Normal expression n=27	42%
	< 75% n= 10 ; ≥75% n= 28	15%/43%

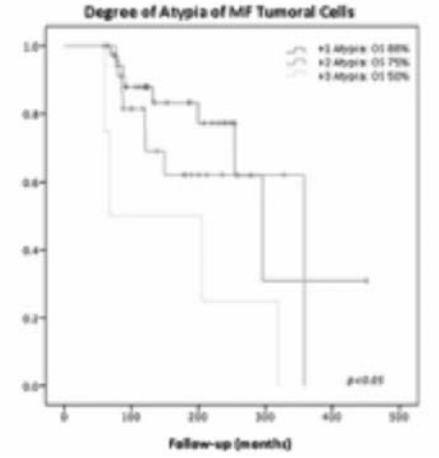

Figure 1.

Methods: Histological preparations of 85 patients diagnosed with with MF were evaluated. Survival analysis was performed with the Kaplan-Meier method. A univariate analysis was performed with clinical variables (stage and age) and anatomopathological variables (*i.e.* intensity of the inflammatory infil-

trate, epidermotropism, cellular atypia, tumor density, presence of folliculotropism and phenotypic alterations) and the proportion and intensity of PD1 expression by tumor cells, the presence of PD-1 positive lymphocytes in the epidermis. Likewise, a Pearson correlation analysis was performed between the degree of atypia and the ratio of PD-1 expression, PD-1 intensity, and loss of CD7 expression in tumor cells. Statistical analysis was performed using the IBM SPSS Statistics version 21.0.
Results: The median follow-up was 125 months (range 6-450 months). Characteristics of patients are in **table 1.** The overall survival (OS) at 10 years was 81%. OS in the early stages was 85% vs.64% in advanced stages (p<0.05). The OS for patients <60 years was 85%, and 75% for patients ≥60 years (p<0.05). Regarding istologic findings, the degree of atypia was the only variable that had an impact in OS.(see Figure 1) The presence of atypia grade +1 had an OS of 88%, grade +2 of 75%, and grade+3 of 50% (p<0.05). We performed a correlation analysis between degree of atypia and the ratio of PD-1 expression, PD-1 intensity, and loss of CD7 expression. A positive correlation was detected, however it was weak (r<0.5).
Summary/Conclusions: MF tumoral cells express PD-1 protein in a high proportion of cases being a potential therapeutic target. Advanced disease, age ≥60 years and the degree of atypia of the tumoral infiltrate had an impact on survival.

E964

CIRCULATING MICRORNAS AS BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

C. Bouvy[1,*], A. Wannez[12], C. Chatelain[1], J.-M. Dogne[1]
[1]Department of Pharmacy, University of Namur, Namur, [2]CHU UCL Namur, Université Catholique de Louvain, Yvoir, Belgium

Background: Diffuse large B-cell lymphoma (DLBCL) is highly heterogeneous in terms of phenotype and treatment response in patients. These characteristics make the prognosis difficult to establish and hinder the use of new personalized treatments in clinical practice. In this context, there is currently a necessity to define new biomarkers enabling a better definition of DLBCL subtypes, prognosis evaluation and an overview of the resistance to chemotherapeutics. We decided here to focus on circulating microRNAs that are found in all biological fluids. This accessibility makes them good candidates for biomarkers studies.
Aims: This research aims at studying microRNAs found in plasma from DLBCL patients and at investigating their potential as biomarkers of survival in these patients. For this purpose, a plasma biobank was created with samples from DLBCL patients at different times of their treatment. This follow-up of microRNAs level during the course of treatment is particularly innovative in this study.
Methods: A plasma biobank from DLBCL patients was set up at the Centre Hospitalier Universitaire (CHU) UCL Namur Yvoir, Belgium (ethical agreement number B039201419613). Informed consents of all patients were obtained. In this way, blood samples from patients were taken before any treatment (C_0), at the administration of the second and the fourth chemotherapeutic cure (C_2 and C_4) and at the remission review (C_f). In the case of an autograft, a sample was taken at the post-graft review (C_{pg}). The first step of this study was the selection of the microRNAs that will be quantified in all the samples of the biobank and that could potentially be used as biomarkers. To this end, a quantification of 377 microRNAs was performed by TaqMan® Low Density Array on the plasma samples of two selected DLBCL patients and one healthy donor with no history of cancer. These DLBCL patients were selected based on their highly different response to treatment. One of them obtained a complete remission after a R-CHOP treatment, while the other presented a refractory disease to the same treatment. Thereafter, we determined some criteria to use in a scoring system to evaluate their potential as biomarkers. In this way, one point was given to a microRNA each time it meets the criteria enabling it to be defined as a potential diagnostic, prognostic and/or remission biomarker, biomarker of a disease progression, biomarker of an inherent resistance to treatment, and/or biomarker of an acquired resistance to treatment.
Results: On the 377 microRNAs quantified into the plasma of the 3 selected donors (2 DLBCL patients and 1 healthy donor), 81 microRNAs were detected. Three microRNAs obtained the highest score of 5 points: miR-197, miR-20a and miR-451. Four points were attributed to miR-122, miR-19b and miR-19a. Two additional microRNAs were also selected: let-7e, for its prognostic value at C0, C2 and C4 and miR-21, for its numerous citations in the literature.
Summary/Conclusions: miR-197, miR-20a, miR-451, miR-122, miR-19a, miR-19b, let-7e and miR-21 have been selected in this study and are currently quantified into the plasma of the entire biobank. Since then, 19 patients have been included in the study and the potential of these microRNAs as biomarker are statistically evaluated.

E965

COMBINED CHEMOTHERAPY PLUS RADIATION THERAPY IS MORE EFFECTIVE IN LIMITED-STAGE DIFFUSE LARGE B-CELL LYMPHOMA OF THE TONSIL

S.-N. Lim[1,*]
[1]Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of

Background: Primary extranodal non-Hodgkin's lymphomas of the head and neck account for 10-20% of all non-Hodgkin's lymphomas. Primary tonsillar lymphoma accounts for less than 1% of head and neck malignancies, although the tonsil is the most common primary extranodal site of head and neck non-Hodgkin's lymphomas.
Aims: The purpose was to evaluate the prognostic factors and treatment outcome of patients with diffuse large B-cell lymphoma (DLBCL) of the tonsil.
Methods: In all, 114 patients with DLBCL of the tonsil with stage I or stage II, treated at multicenter in Korea, from September 1995 to April 2011, were included. The median age was 59 years and the majority of patients (61%) were male. Systemic symptoms were present in 6% of patients. International prognostic index (IPI) score was 0 in 54 patients (48%), 1 in 40 (35%), 2 in 14 (12%), and 3 (3%). Ten patients (8%) showed elevated level of lactate dehydrogenase (LDH). Treatment consisted of a combination of chemotherapy (CTx) and radiotherapy (RTx) for 38 patients (34%) and 72 patients (65%) received CTx only. Among those receiving RTx, the median RTx dose was 39 Gy.
Results: After median follow-up of 32 months (range,0.4-106 months), event free survival (EFS) and overall survival (OS) were 25.9% and 42.5%, respectively. Significant prognostic factors included: age (≥ 60 year-old *vs* <60 year-old), LDH level (> upper normal limit and ≤upper normal limit), IPI score (0-1 *vs* 2-3), and treatment (CTx plus RTx *vs* CTx only). On multivariate analysis; LDH level (hazard ratio [HR], 10.522; 95% confidence interval [CI], 2.548-43.449, p=0.001) and treatment (HR, 12.393; 95% CI 2.151-71.410) were independent prognostic factor of EFS and age (HR, 8.920; 95% CI 1.089-73.053, p=0.043), LDH (HR, 8.316; 95% CI 1.914-36.127, p=0.005), and treatment (HR, 8.943; 95% CI 1.089-73.425) retained statistical significance in OS.

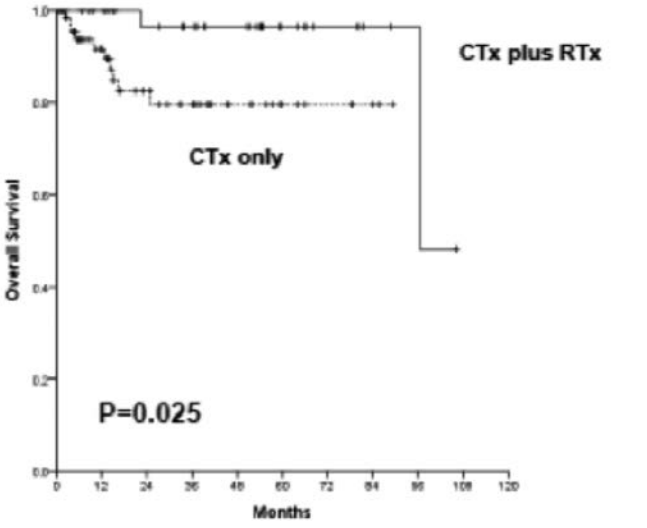

Figure 1.

Summary/Conclusions: LDH level and age significantly influence outcome. A combined modality treatment, consisting of CTx and RTx, results in a satisfactory outcome in patients with stage I or II DLBCL of the tonsil.

SEQUENTIAL TREATMENT WITH BENDAMUSTINE, RITUXIMAB AND DEXAMETHASONE FOLLOWED BY RITUXIMAB CONSOLIDATION AND LENALIDOMIDE MAINTENANCE FOR FRAIL ELDERLY PATIENTS WITH AGGRESSIVE B-NON HODGKIN LYMPHOMA

L. Pezzullo[1], L. Mettivier[1], A. Bruno[1], R. Bianco[1], S. Annunziata[1], R. Fontana[1], B. Serio[1], C. Martorelli[1], R. Guariglia[1], R. Rosamilio[1], B. Marcelli Graziosi[1], C. Selleri[1,*]
[1]Hematology, AUO San Giovanni di Dio e Ruggi D'Aragona, Salerno, Italy

Background: Frail elderly patients with aggressive B non-Hodgkin Lymphoma (a-B-NHL) in most cases show comorbidities such as to preclude the use of antracycline-based standard regimen. Although significant advances have recently been achieved in the therapy of older patients with a-B-NHL, there is still need for treatment strategies able to overcome the impact of drug toxicity in elderly frail patients.
Aims: The safety and efficacy of bendamustine and rituximab plus dexamethasone (RD-Benda) regimen were prospectively investigated in 14 elderly and frail patients with newly diagnosed a-B-NHL.

Methods: Fourteen (4 female, 10 male) consecutive frail elderly patients (median age: 79 years; range 68-86 years) with a-B-NHL (11 DLBCL, 1 Burkitt NHL, 1 Burkitt-like NHL and 1 Mantle cell lymphoma) were enrolled in a phase II study with bendamustine 70mg/m^2 i.v. on days 1 and 2, rituximab 375mg/m^2 *i.v.* on day 1and oral dexamethasone 20mg total dose on days 1-4 for four cycles. Frailty criteria were age > or =80 years, or age > or =70 years associated with three or more grade 3 comorbidities or at least one grade 4 comorbidity according to the cumulative illness rating scale (CIRS), as well as not self-sufficient or the presence of geriatric syndromes.
Results: P*atients* who showed complete (CR) or partial response (PR) after the fourth induction cycle of RD-BENDA started a consolidation course with four weekly doses of rituximab (375mg/m^2 *i.v.*) followed, in the case of persistence of CR or PR, by a maintenance treatment with monthly courses of lenalidomide (10mg/m^2, days 1-21). All patients performed G-CSF prophylaxis to avoid febrile neutropenia. Patients with progressive disease after RD-BENDA started maintenance therapy with monthly courses of full dose lenalinomide. PET-CT scans were performed for the assessment of therapy response after RD-BENDA induction course and after rituximab consolidation. After a median follow-up of 6 months (range 2-18), the overall response rate was 81%, with CR and PR of partial response rates of 63 (n=7) and 21% (n=2) respectively. Two patients died due to multiple organ failure and disease progression after 1 and 8 months from diagnosis, respectively. In our frail and elderly patient cohort, the sequential treatment strategy was well-tolerated. After R-BENDA cycles, grade II infectious disease was observed in 2/11 patients (18%) and DNA-CMV reactivation was detected in other 2 additional patients (18%). However, 2 out of five patients who started maintenance lenalidomide treatment discontinued therapy for renal and hematological grade 3 toxicity. At the time of analysis, the estimated median *18-month* progression free survival (PFS) and overall survival (OS) were 75 and 66%, respectively.
Summary/Conclusions: Our preliminary data show that sequential treatment with RD-BENDA followed by four weekly doses of rituximab and finally by lenalidomide maintenance is a feasible and safe therapy option in frail elderly a-B-NHL patients, but needs to be assessed in a larger subsequent trial.

E968

CLINICAL RELEVANCE OF SARCOPENIA IN DIFFUSE LARGE B-CELL LYMPHOMA - TWO ARE BETTER THAN ONE

S.-I. Go[1], M.J. Park[2], G.-W. Lee[1,*]
[1]Internal Medicine, [2]Radiology, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Sarcopenia is known to be associated with poor clinical outcome in patients with diffuse large B-cell lymphoma (DLBCL). There is no consensus concerning the optimal method to define sarcopenia in DLBCL.
Aims: In this study, given the uncertainty about the optimal SMI to define clinically meaningful sarcopenia in DLBCL, we compared the characteristics and clinical outcome between sarcopenic patients determined by L3 skeletal muscle index (L3-SMI) and those determined by pectoralis muscle SMI (PM-SMI) who were treated with standard front-line R-CHOP therapy. Furthermore, the synergistic role of L3- and PM-SMIs as prognostic markers was also investigated.
Methods: We retrospectively reviewed 193 DLBCL patients treated with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy. Sarcopenia was classified by the region where the pretreatment skeletal muscle index (SMI) was measured.
Results: Both the sarcopenia-L3 and sarcopenia-pectoralis muscle (PM) groups had increased incidences of severe treatment-related toxicities and treatment discontinuation compared with the non-sarcopenia-L3 and non-sarcopenia-PM groups, respectively. The sarcopenia-L3 and non-sarcopenia-L3 groups had 5-year overall survival (OS) rates of 40.5% and 67.8% (p<0.001), respectively. The sarcopenia-PM and non-sarcopenia-PM groups had 5-year OS rates of 35.9% and 69.0% (p<0.001), respectively. When the sarcopenia-L3 alone and sarcopenia-PM alone groups were compared, there were no differences in baseline characteristics, treatment toxicity, or survival. In multivariate analysis, when compared with the non-sarcopenia-both group, OS was significantly worse in the sarcopenia-both group (HR, 2.480; 95% CI, 1.284-4.792; p=0.007), but not in patients with either sarcopenia-L3 alone or sarcopenia-PM alone (p=0.151).
Summary/Conclusions: L3- and PM-SMIs are equally useful to define sarcopenia, which is related to intolerance to R-CHOP therapy and to worse survival in patients with DLBCL. More prognostic information can be obtained when these two SMIs are combined to define sarcopenia.

E969

INTENSIFIED TREATMENT REGIMENS IMPROVE EVENT-FREE AND OVERALL SURVIVAL IN YOUNGER NEWLY DIAGNOSED HIGH-RISK PATIENTS WITH B-LARGE CELL LYMPHOMA; A RETROSPECTIVE OBSERVATIONAL STUDY OF KROHEM

S. Basic-Kinda[1,*], M. Lucijanic[2], I. Hude[1], Z. Prka[2], Z. Mitrovic[2], I. Radman[1], T. Valkovic[34], D. Radic-Kristo[56], D. Lozic[7], D. Nemet[8], V. Pejsa[29], I. Aurer[19]
[1]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, [2]Division of Hematology, Department of Internal Medicine, University Hospital Dubrava, Zagreb, [3]Division of Hematology, Department of Internal Medicine, University Hospital Centre Rijeka, [4]Medical School, University of Rijeka, Rijeka, [5]Division of Hematology, Department of Internal Medicine, University Hospital Merkur, Zagreb, [6]Medical School, University of Osijek, Osijek, [7]Division of Hematology, Department of Internal Medicine, University Hospital Centre Split, Split, [8]KroHem, [9]Medical School, University of Zagreb, Zagreb, Croatia

Background: Standard therapy for newly diagnosed B-large cell lymphoma (B-LCL) is R-CHOP. Patients with high-risk disease have unsatisfactory outcomes. Non-randomized trials have suggested that intensified regimens, such as R-CHOEP14 and DA-R-EPOCH, improve treatment results in younger patients.
Aims: We performed this analysis to compare response rates, event-free (EFS) and overall survival (OS) rates of newly diagnosed patients with high-risk disease treated with R-CHOP21 and more intensive regimens (R-CHOEP14 and DA-R-EPOCH).
Methods: Outcomes of B-LCL patients younger than 60 with aaIPI ≥2 treated at two different centres with R-CHOEP14 and DA-R-EPOCH were collected retrospectively from patient files and compared to outcomes of patients with same characteristics treated with R-CHOP21 from the registry of KroHem, the Croatian Cooperative Group for Hematologic Diseases. All three regimens were administered according to standard guidelines for 6-8 cycles. Patients in PR or with initial bulky disease were irradiated after the end of systemic treatment. Twelve patients treated with DA-R-EPOCH were autografted in 1st remission.
Results: 54 patients were treated with R-CHOP21, 40 with R-CHOEP14 and 22 with DA-R-EPOCH. R-CHOEP14 and DA-R-EPOCH treated patients did not differ in response rates, EFS and OS and were grouped together for further analysis. R-CHOP treated patients had less frequently bulky disease (25% *vs* 49%, P=0.007) than more intensively treated patients; there was no difference in age, gender, stage, elevated LDH or PS ≥2. Patients receiving R-CHOP had similar response rates as those receiving more intensive regimens (80% *vs* 85%, P=0.405), but inferior EFS (HR 2.12, 95% C.I. [1.09-4.12], P=0.028) and OS (HR 2.15, 95% C.I. [1.07-4.3], P=0.034) (Figure 1). 5-year EFS rates were 58% and 78% and 5-year OS rates 60% and 80% for R-CHOP21- and more intensively treated patients, respectively. Differences in outcomes between R-CHOP and intensified regimens remained significant in a multivariate Cox regression model adjusted for age, gender and presence of bulky disease (HR 2.45, 95% C.I. [1.11-5.4], P=0.026 for OS and HR 2.46, 95% C.I. [1.16-5.24], P=0.019 for EFS).

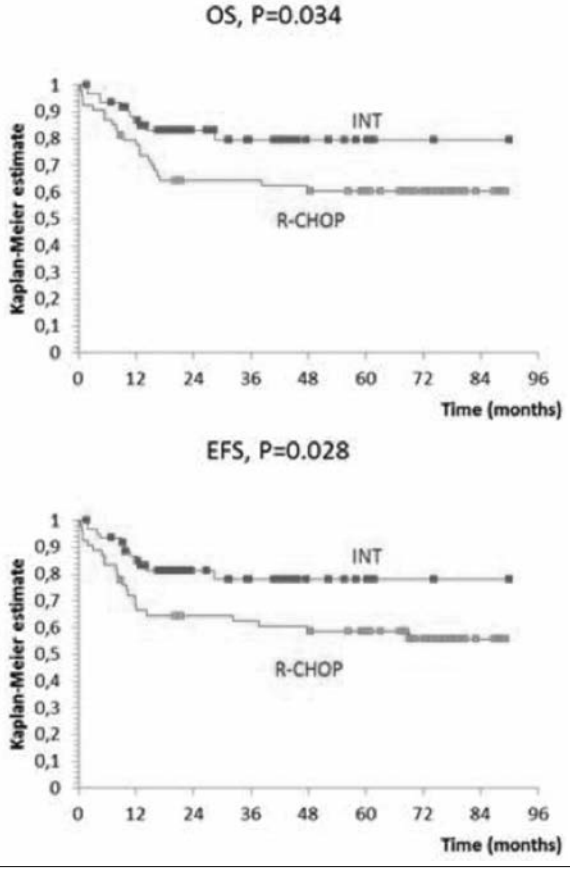

Figure 1.

Summary/Conclusions: Our data suggests that the addition of etoposide to R-CHOP and increase in dose-intensity improve EFS and OS of younger patients with newly diagnosed high-risk B-LCL. R-CHOEP14 and DA-R-EPOCH seem to be similarly effective in this setting.

E970

HIGH COMORBIDITY INDEX ALONG WITH HIGH NCCN-IPI STRONGLY INFLUENCE SURVIVAL OF DIFFUSE LARGE B CELL LYMPHOMA PATIENTS: SERBIAN LYMPHOMA GROUP EXPERIENCE

J. Jelicic[1,*], D. Antic[2], M. Todorovic Balint[2], B. Andjelic[2], O. Markovic[3], I. Petkovic[4], V. Nikolic[5], J. Bila[2], V. Djurasinovic[2], A. Sretenovic[1], V. Vukovic[1], M. Smiljanic[1], S. Sretenovic[6], B. Mihaljevic[2]

[1]Clinic of Hematology, Clinical Center of Serbia, [2]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, [3]Clinical Hospital Center "Bezanijska Kosa", University of Belgrade, Belgrade, [4]Clinic of Oncology, University Clinical Center Nis, [5]Clinic of Hematology, Clinical Center Nis, Nis, [6]Clinic of Hematology, Clinical Center Kragujevac, Kragujevac, Serbia

Background: A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPI) so far. However, some patients with low risk according to NCCN-IPI have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be analyzed.
Aims: The aim of this study was to evaluate prognostic significance of current indexes such as International Prognostic Index (IPI), NCCN-IPI, and the influence of comorbidities on the overall survival (OS) of patients with newly diagnosed diffuse large B cell lymphoma (DLBCL).
Methods: A total of 708 patients (363 males/345 females) with the median age of 58 years (range 18-89) were included in the study. Majority of patients received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone) protocol, 652 (92.1%), while 29 (4.1%) received R-EPOCH (Rituximab, Etoposide, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone), and 27 (3.8%) received R-CVP (Rituximab, Cyclophosphamide, Vincristine, Prednisone).
Results: According to the Ann Arbor classification, stage I and II had 332 patients (46.9%), while stage III and IV had 376 patients (53.1%). Bulky disease was present in 201 patients (28.4%), and B symptoms in 437 patients (61.7%). Poor European Cooperative Oncology Group (ECOG) performance status (≥2) had 145 patients (20.5%). Bone marrow involvement was present in 97 patients (13.7%). At least one comorbid condition had 309 patients (43.6%), while high Charlson Comorbidity Index (CCI) had 44 patients (6.2%). Majority of patients had cardiovascular disorders (223, 31.5%), endocrinological (63, 8.9%), neurological (20, 2.8%), reumatological (19, 2.7%), previous malignancy (19, 2.7%), pulmonary (18, 2.5%), psychiatric (13, 1.8%), nephrotic (8, 1.1%), autoimmune (6, 0.8%), and other (13, 1.8%). According to IPI, low, low intermediate, high intermediate and high risk had 332 patients (46.9%), 174 (24.6%), 132 (18.6%), and 70 (9.9%), respectively, while according to NCCN-IPI, 139 (19.6%) patients had low risk, 335 (47.3%) low intermediate, 198 (28.0%) high intermediate, and 36 (5.1%) high risk. Overall treatment response (ORR) was achieved in 615 patients (86.9%). Disease relapse was confirmed in 116/615 patients (18.9%). The patients with B symptoms (Log Rank=18.50, p<0.0001), and bulky disease (Log Rank=14.79, p<0.0001) had inferior OS compared to those without B symptoms or bulky disease. All parameters incorporated in IPI, as well as in NCCN-IPI, were significantly associated with OS (p<0.01). Moreover, the patients with at least one comorbidity had inferior OS (Log Rank =5.41, p=0.20), as well as those with high CCI ≥2 (Log Rank =7.59, p=0.006). Regarding OS, IPI (Log Rank=97.36, p<0.0001), and NCCN-IPI (Log Rank=102.29, p<0.0001) confirmed its prognostic significance. Furthermore, the patients with high CCI had significantly inferior median OS in the high risk group according to IPI (19 months *vs* 37 months), and NCCN-IPI (12 months *vs* 19 months).
Summary/Conclusions: NCCN-IPI represents useful prognostic index in DLBCL patients, and can better describe patients within risk groups, compared to IPI. Moreover, comorbidities contribute to inferior survival through frailty, drug dose reduction and poorer tolerability.

E971

SUBSTITUTING DOXORUBICIN WITH ETOPOSIDE IN R-CHOP RESULTS IN A REGIMEN WITH SIMILAR EFFICACY FOR TREATMENT OF NEWLY DIAGNOSED ELDERLY PATIENTS WITH B-LARGE CELL LYMPHOMA (B-LCL)

I. Hude[1,*], S. Basic-Kinda[1], I. Radman[1], S. Dotlic[2], M. Kralik[3], M. Vodanovic[1], P. Roncevic[1], L. Galunic-Bilic[4], M. Dobrenic[56], A. Ostojic[1], D. Dujmovic[6], I. Aurer[16]

[1]Division of Hematology, Department of Internal Medicine, [2]Department of Pathology and Cytology, [3]Department of Radiology, [4]Department of Oncology, [5]Department of Nuclear Medicine, University Hospital Centre Zagreb, [6]Medical School, University of Zagreb, Zagreb, Croatia

Background: R-CHOP is standard front-line treatment for B-LCL. However, anthracycline-induced cardiac toxicity limits its use in elderly and patients with preexisting heart disease. R-CEOP, in which doxorubicin is substituted with etoposide, has been suggested as a potential solution of this problem, but reports on the efficacy of this regimen vary substantially, especially in patients with non-GC DLBCL. We have been using this regimen regularly for front-line treatment of patients with B-LCL and preexisting heart disease and present here our experience.
Aims: To compare outcomes of newly diagnosed patients with B-LCL treated at a single institution with R-CEOP and R-CHOP.
Methods: We performed a retrospective analysis of all newly diagnosed B-LCL patients treated with R-CEOP at our centre from 2011 to 2016 and compared them to patients 60 years or older treated during the same period with R-CHOP, the standard regimen used at our centre for non-frail elderly without significant cardiac comorbidities. The dose of etoposide in R-CEOP was 50mg/m^2 iv or 100mg/m^2 orally daily for 3 days. Both regimens were given every 3 weeks for 6-8 cycles. Patients with initial bulky disease or in PR after systemic treatment were irradiated.
Results: 31 patients, 15 male and 16 female, received R-CEOP and 48, 25 male and 23 female, R-CHOP. Patients in the former group were older (median age 77 y, range 58-87 *vs* median age 66 y, range 60-83), had more often low performance status (81% *vs* 31%) and advanced disease (84% *vs* 54% stage 3 and 4) resulting in a significantly higher proportion of patients with IPI 3-5 (74% *vs* 40%, p=0.019). Proportions of patients with increased LDH were similar between the groups. There were no significant differences in frequency of grade 3-4 toxicity between the regimens; 48% of patients in both groups required emergency hospitalization; thrombocytopenia or anemia occurred in 16% of R-CEOP and 23% R-CHOP treated patients, infections in 32% and 31% and cardiovascular events in 16% and 21%. However, 7 patients (23%) in the R-CEOP group died during treatment due to adverse effects in comparison to 4 (8%) in the R-CHOP group. Efficacy was similar, 65% responded to R-CEOP and 79% to R-CHOP. After a median follow-up of survivors of 27 mo, 3y-OS was 55% in the R-CEOP group and 52% in the R-CHOP group; 3-y EFS was 50% and 50%, respectively (figure). Outcomes of patients with GC and non-GC DLBCL categorized according to Hans's algorithm were similar irrespective of treatment.

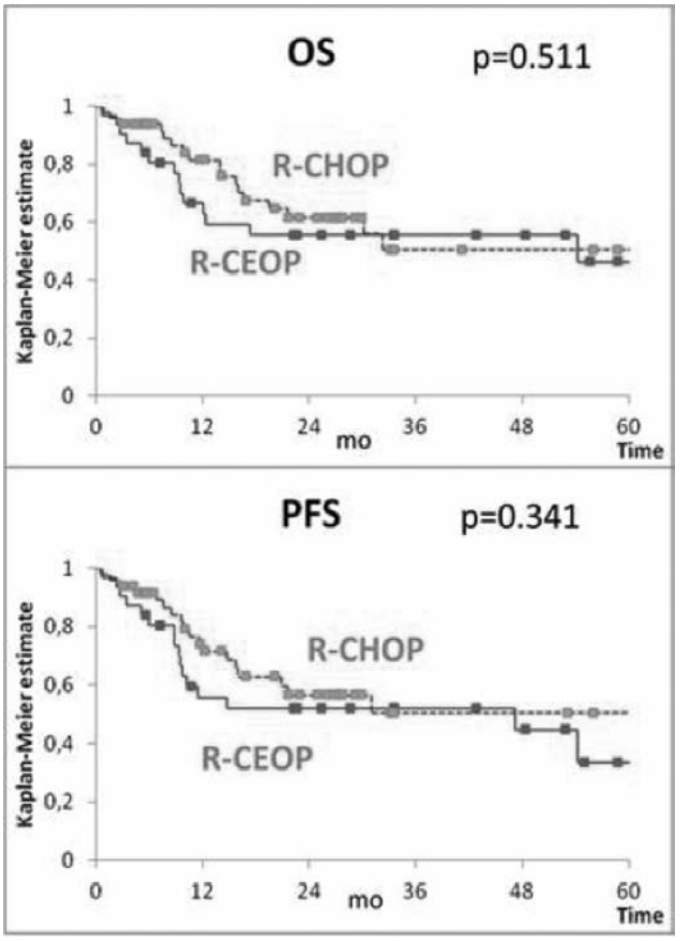

Figure 1.

Summary/Conclusions: Long-term outcomes of newly diagnosed B-LCL patients treated with R-CEOP seem as good as those achieved with R-CHOP irrespective of cell of origin. Observed differences in treatment-related mortality were most probably caused by differences in age, comorbidities and performance status. R-CEOP should be considered as a regimen of choice for B-LCL patients with cardiac contraindications for anthracycline treatment.

E972

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDERS: A SINGLE-CENTER CASE SERIES

C. De Miguel[1,*], B. Navarro[1], J. Martín[2], P. Martín[2], G. Anze[1], A. Alarcón[1], R. Forés[1], C. Bellas[2], J.R. Cabrera[1]
[1]Hematology, [2]Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Post-transplantation lymphoproliferative disease (PTLD) is a complication of both solid organ transplant (SOT) and haematopoietic cell transplant (HCT) and represent a very heterogeneous group.
Aims: The objective of this study is to evaluate the epidemiology, clinical features, characterization and therapeutic management of this disease.
Methods: We evaluated a total of 52 patients diagnosed between May 1995 and February 2017. We analyzed the following data: type of transplantation, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.
Results: Among the 52 patients, 31 were men (59.6%) and 21 women. PTLD after SOT were 45 (86.5%), of which 16 were after liver transplant (35.6%), 14 cardiac (31.1%), 9 pulmonary (20%), 4 renal (8.9%) and 2 double (cardiac-pulmonary and cardiac-renal) (4.4%). There were 7 PTLD after HCT, 2 identical HLA family donor, 2 unrelated donor, 2 dual umbilical cord blood and 1 autologous. Of the 52 PTLD, 48 were B lymphomas (92.3%), of which 26 were diffuse large B-cell lymphomas (DLBCL) (54.2%), 7 polymorphic (14.6%), 7 low-grade (14.6%), 4 Burkitt lymphomas (8.3%), 1 Hodgkin's lymphoma (2.1%) and 3 were non-classifiable. Other 4 PTLD were T lymphomas (6.7%), 2 anaplastic, 1 T/NK lymphoma, and 1 gamma/delta T lymphocytosis. 35/52 PTLD were EBV + (67.3%). The median time of immunosuppression was 123 months in renal transplant, 93 months in liver, 85.5 months in cardiac, 51 months in lung and 3 months in HCT. Histologically, it was 96 months in T lymphomas and 80 months in B lymphomas, being 51 months in EBV + and 124 months in EBV-. Fifty percent of Burkitt lymphomas were diagnosed after lung transplant, while 85% of low-grade lymphomas were diagnosed after liver transplant. Clinical stage was III/IV in 73% of the patients (38). Among the 52, 45 received treatment (86.5%), 37 with immunochemotherapy (82.2%) and 8 with Rituximab (17.8%). Three patients responded to reduction of immunosuppression (5.8%) and 3 did not receive any treatment for early death (5.8%). At the time of writing, 19 patients remain alive (36.5%) and 33 have died. The median survival of these patients was 19.5 months (0-198).
Summary/Conclusions: PTLD constitute a very heterogeneous group. Its appearance is much earlier in the HCT than in the SOT and, within this latter group, it is earlier after lung transplant and later after renal transplant. The most common type in our series is DLBCL. The majority are related to EBV, so post-transplant monitoring is essential, and its diagnosis is earlier than in EBV-. Most low-grade lymphomas appear post-liver transplant, either in relation to virus C or with autoimmune diseases. Survival is significantly lower than in other primary LPS. :AR-SA'>We analyzed the following data: type of transplantation, immunosuppression used in both induction and maintenance, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

E973

SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) USING A UNITED STATES (US) ELECTRONIC MEDICAL RECORD (EMR)-BASED COHORT

A. Galaznik[1,*], J. Bell[1], L. Hamilton[2], A. Ogbonnaya[2], A. Raju[2], K. Hennenfent[2], M. Eaddy[2], Y. Shou[1]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [2]Xcenda LLC, Palm Harbor, United States

Background: In the rituximab era, the recommended first-line therapy (1LT) in DLBCL patients who can tolerate combination therapy is rituximab combined with chemotherapy. For refractory/relapsed disease, high-dose chemotherapy with stem cell transplant, combination chemotherapy, or single-agent rituximab are considered. While the efficacy of rituximab has been shown in clinical trials, few studies have evaluated survival outcomes in patients seen in routine clinical care.
Aims: We evaluated survival outcomes in a US population of newly diagnosed DLBCL patients seen in routine clinical care.
Methods: In this retrospective study, adult patients ≥18 years old with newly diagnosed DLBCL were identified from the Humedica, a large US electronic medical record database, between 01/01/08 and 07/31/15. DLBCL diagnosis was determined by the presence of ≥1 inpatient record or ≥2 outpatient records with DLBCL diagnosis codes; the first DLBCL record served as the index date. Following the index date, initiation of 1LT for DLBCL was required. For the assessment of the survival outcomes, patients were evaluated from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15). Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using unadjusted Kaplan-Meier analyses.
Results: 1,436 newly diagnosed DLBCL patients who initiated 1LT met the patient selection criteria. 54.0% were male, and the mean age was 66.4 years (SD: 13.7). At baseline, 27.4% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (20.3%), chronic pulmonary disease (15.5%), and moderate to severe renal disease (9.5%). In 1LT, 92.1% of patients received combination therapy, with R-CHOP (63.5%) being the most common combination therapy. 7.9% of patients received monotherapy upfront, with rituximab (77.2%) being the most commonly used single agent. At 2 years following initiation of 1LT, the Kaplan-Meier OS and PFS were 79.2% and 67.3%, respectively. Median OS was not reached, and median PFS was 53.9 months (95% confidence interval: 45.2, 61.5). OS and PFS were also compared among patients receiving monotherapy *vs* combination therapy in unadjusted analysis. At 2 years, OS was 80.2% for patients receiving combination therapy *vs* 67.4% (P=0.0093) for patients receiving monotherapy. Also at 2 years, PFS was 68.3% for patients receiving combination therapy *vs* 55.1% (P=0.0051) for patients receiving monotherapy.
Summary/Conclusions: In this population of patients with newly diagnosed DLBCL receiving 1LT, survival outcomes at 2 years were significantly improved for patients treated with combination therapy *vs* monotherapy. Future analysis will explore the differences in clinical characteristics of patients treated with monotherapy *vs* combination therapy in the 1LT setting.

AN EXPERIENCE WITH LONG ACTING FACTOR VIII PROPHYLAXIS IN PAEDIATRIC AND YOUNG ADULT PATIENTS WITH HAEMOPHILIA A

S. Verma[1], A. Tripathi[1,*], G. Suri[1], N. Kumar[1], R. Kushwaha[1], A. Kumar[1], P. Kumar[1]
[1]K G. Medical University Lucknow, Lucknow, India

Background: Hemophilia is an X linked inherited bleeding disorder. Recurrent Joint bleeds and muscle bleeds are the commonest manifestations leading to long term comorbidities in hemophilia. High dose factor prophylaxis has been proven to be very effective in preventing joint problems in western world. We look for a cost effective and feasible way for Indian patients in terms of reduced dose and frequency of factor infusion. Data on prophylaxis with low dose long acting factor infusion on twice weekly dosing schedule is limited.
Aims: To study the efficacy and safety of long acting factor VIII (Eloctate) for tertiary prophylaxis in pediatric and young adult patients with moderate and severe haemophilia A.
Methods: Thirty eight patients with moderate and severe haemophilia A without inhibitors and age range from 1 to 25 years were included in this study. Patients were initially observed for 4 months during which they received therapeutic doses of long acting factor VIII, ELOCTATE (Factor VIII with Fc Fusion Protein) on episodic basis after clinical bleed. In next 4 months they received prophylactic ELOCTATE, given intravenously at doses of 20 unit/kg body weight on twice weekly schedule. Annual bleeding rates, school absenteeism, emergency visits, aspects of quality of life and joint scores were compared during observation and prophylaxis period.
Results: Total number of bleeds during observation and prophylaxis period was 607 and 90 respectively. Annual bleeding rate was 47.9 during observation period and 7.1 during prophylaxis. There was 85.1% reduction in bleeding rates on prophylaxis. School/college absenteeism was 3.1 days/ month and 0.84 days/month during observation and prophylaxis respectively. Emergency visits were significantly more during observation. None of the patients developed inhibitors and two patients had superficial thrombophlebitis during prophylaxis. Quality of life assessment using KIDSSCREEN QOL questionnaire showed moderate to marked improvement in quality of life domains during prophylaxis.
Summary/Conclusions: Low dose, twice a week, long acting factor VIII prophylaxis can be a reasonable option for patients with haemophilia A in developing countries. It significantly reduces joint bleeds, school absenteeism, Joint scores significantly without risk of inhibitor formation and also improves all domains of quality of life.

E975

NOVEL MUTATIONS IN THAI CHILDREN WITH CONGENITAL FACTOR VII DEFICIENCY

D. Sosothikul[1,*], T. Pusongchai[1], R. Ittiwut[1], P. Komvilaisak[2], C. traivaree[3], K. Suphapeetiporn[1]
[1]Department of Pediatrics, Chulalongkorn University, Bangkok, [2]Department of Pediatrics, Khon Kaen University, Khon Kaen, [3]Department of Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

Background: Congenital factor VII (FVII) deficiency is a rare autosomal recessive coagulation disorder resulted from mutations in the FVII gene (*F7*). The disease severity is not correlated with FVII levels but might be determined by molecular defects in *F7*.
Aims: To delineate the phenotypic and genotypic characteristics of patients with congenital FVII deficiency
Methods: We described demographic data, clinical manifestations, and outcome of patients with congenital FVII deficiency. *F7* mutation analysis was performed by PCR-direct sequencing.
Results: Of the ten patients diagnosed with FVII deficiency, five (50%) were males. The median age (range) at diagnosis was 19 days old (1-730). Consanguinity was found in 50% of the patients. Of the nine patients (90%) classified as severe, six patients presented with intracerebral hemorrhage within the first month of life, two presented with gastrointestinal bleeding and one presented with hemarthrosis. There were eight different alterations identified. Four have been previously reported (c.1091G>A (p.R364Q), c.1238G>A (p.R413Q), c.1256C>T (p.T419M), and c.681G>T (IVS6+1T)). Four were novel (c.1192G>T (p.D398Y), c.1313G>T (p.G420V), c.291+2T>C (IVS3+2T>C), and IVS6-2A>G) and associated with major bleeding especially during infancy.
Summary/Conclusions: This study reported Thai children with congenital FVII deficiency presented with life-threatening bleeding especially in the first year of life. Pathogenic including newly identified variants in the *F7* gene were detected in all cases. Genetic counseling can be appropriately provided to reduce the risk of disease recurrence in the families at risk.

E976

RETROSPECTIVE EVALUATION OF PHENOTYPE AND MANAGEMENT OF A-HYPO-FIBRINOGENEMIA IN A COHORT OF ITALIAN PATIENTS

C. Santoro[1,*], F. Massaro[1], E. Baldacci[1], G. Ferrara[1], A. Ferretti[1], R.C. Santoro[2], S. Pasca[3], G. Castaman[4], F. Peyvandi[5], R. Foà[1], M.G. Mazzucconi[1]
[1]Cellular Biotechnology and Hematology, Hematology Sapienza University, Rome, [2]Oncohaematology Department, Haemostasis and Thrombosis Service- Pugliese-Ciaccio Hospital, Catanzaro, [3]Center for Hemorrhagic and Thrombotic Diseases, University Hospital of Udine, Udine, [4]Center for Bleeding Disorders, Careggi University Hospital, Florence, Florence, [5]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

Background: Afibrinogenemia (AF) and hypo-fibrinogenemia (HF) patients (pts) experience hemorrhages or thromboses, and the clinical management can be difficult.
Aims: To obtain information on AF/HF clinical phenotype and management.
Methods: This is a spontaneous, retrospective, multicenter national study. Data are collected from clinical records.
Results: 2 AF and 12 HF pts have been enrolled (6M, 8F). Median follow-up: 39 months (1-553). Median fibrinogen activity/antigen level: 78mg/dL (0-150)/73mg/dL (0-140). Five pts experienced epistaxis, hematomas, ecchimoses, menometrorrhagia, intra-abdominal bleeding, gum bleeding, hemarthrosis. Fresh frozen plasma, fibrinogen concentrate (FC), cryoprecipitate, whole blood, tranexamic acid were administered in the majority of these events. One ischemic stroke, 1 lower limb arterial and 1 cerebral sinus thrombosis, 1concomitant aortic and inferior vena cava thrombosis occurred: 3 events during FC therapy, 1 during puerperium. Heparin, low molecular weight heparin (LMWH), anti-platelet agents, fibrinolytic agents, warfarin were then administered. One gastrectomy, 1 lower limb amputation, 5 gynecological, 1 otorhinolaryngological and 1 plastic surgery were performed in 2AF and 3 HF pts: in AF pts, FC or FFP prohylaxis was administered while in HF pts was not. Bleeding was observed after 2 surgeries performed without prophylaxis. Eight pregnancies were initiated in 3 HF women. Two spontaneous deliveries (SD) and 2 cesarian sections (CS) were performed; 4 abortions occurred. FC prophylaxis and LMWH were administered during pregnancy in 3 and 4 cases, respectively. One venous thrombosis, 2 hemorrhages, 1 DIC and 4 complicated pregnancies were recorded. FC was administered at delivery and LMWH during puerperium, for the 2 CS. No complications at delivery occurred.
Summary/Conclusions: AF and severe HF pts experience severe hemorrhagic/thrombotic events. The intervening clinical situations are difficult to manage. Further large scale data collections are necessary in order to provide useful information to better characterize and manage patients suffering from these rare diseases.

E977

RETROSPECTIVE REVIEW OF FOUR DAYS OF VON WILLEBRAND'S FACTOR AS SURGICAL PROPHYLAXIS IN VON WILLEBRAND'S DISEASE

S. Bal[1,*], M.K. Riaz[1], D. Peters[1], J. Palascak[1], S. Girnius[1]
[1]Hematology and Oncology, University of Cincinnati Medical Center, Cincinnati, United States

Background: Von Willebrand disease (vWD) is the most common inherited bleeding disorder that manifests as easy bruising, mucocutaneous bleeding and excessive hemorrhage with invasive procedures. In 2007, Humate-P, a lyophilized concentrate of purified VWF and FVIII, was approved in the United States for treatment and prophylaxis. Current guidelines per National Heart, Lung, and Blood Institute (NHLBI) Expert Panel recommend 40-60 U/kg preoperatively, followed by maintenance dose of 20-40 U/kg for 7-14 days for major surgery and 5 days for minor surgery. Here, we report a single-institution experience of a short course of Humate-P as surgical prophylaxis.
Aims: To assess if an abbreviated schedule of Humate-P given as perioperative dose of 40 U/Kg for 2 days (one dose pre-op and one post op) for extensive dental procedures and for 4 days (one dose pre-op and for 3 days post-op) for minor and major surgical procedures as surgical prophylaxis would result in equi-efficacious hemostasis without compromising patient outcomes.
Methods: We retrospectively identified 202 patients with known diagnosis of VWD at our institution that underwent surgical procedures requiring prophylaxis between 2002-2017. Ninety elective surgical events occurred among these patients that required peri-operative prophylaxis with Humate-P. These patients were treated with peri-operative dose of 40 U/Kg on D0-1 for extensive dental procedures and for D0-3 for minor and major surgery. The definition of bleeding risk was based on NHLBI guidelines.
Results: Eighteen (20%) were males and 72 (80%) were females. Type I VWD constituted 94.4% (85/90). 84.4% Caucasian patients, 8.8% African American, 1.1% South Asian. Twenty-nine (32.2%) procedures were categorized as major surgeries, 51 (56.6%) were minor and 2 (2%) uncomplicated dental procedures. Eighty-four (93.3%) achieved excellent hemostatic efficacy defined as clinical hemostasis within normal limits. Six (6.6%) surgeries had good hemostatic efficacy defined as slight oozing. Five (6%) patients required blood transfusions

(1-3 units packed red blood cells). 100% excellent-good outcomes similar to longer factor replacement schedules were noted. No deaths or thromboembolic events were noted. One patient required re-admission for post-op hematoma following gynecologic procedure. Thirty-four (37.7%) patients were discharged either same day or after overnight observation. Von Willebrand factor (VWF) is necessary to form a platelet plug by recruiting Factor VIII and platelets to damaged vessels walls. We believe that four days is sufficient time for the formation a stable platelet plug and further downstream hemostasis is presumably VWF-independent. Here, we demonstrate safety and efficacy of a two to four day regimen of Humate-P, with only one person requiring re-admission for a post-operative hematoma. Current guidelines for surgical prophylaxis of VWD are based on expert opinion and lack level 1 evidence. Prolonged exposure may place patients at risk for unnecessary side effects, including thromboembolism and protracted hospitalization, and also causes financial toxicity. One unit of Humate-P costs 1.2 USD, which translates to enormous cost savings. Cumulatively, we were able to save ~1.5million USD in these 90 surgical events using our abbreviated schedule.
Summary/Conclusions: Perioperative dose of 40U/Kg for 2 days (one dose pre-op and one post op) for extensive dental procedures and for 4 days (one dose pre-op and for 3 days post-op) for minor and major surgical procedures are associated with excellent hematologic outcomes and significant cost savings. However, this is single institutional data with limited number of patients and there remains a need for further studies to better define the exact dosing and duration of surgical prophylaxis.

E978

AUDIT ON MANAGEMENT OF HIGH INTERNATIONAL NORMALIZED RATIO (INR) IN WARFARINISED INPATIENTS
H. Hendra[1], V. Gorur[1,*], W. Nagi[1]
[1]Haematology, Broomfield Hospital, Chelmsford, United Kingdom

Background: Warfarin is the commonest used oral anticoagulant with an effective antidote. The British Committee for Standards in Haematology guidelines recommend administration of 25-50µg of four factor Prothrombin Complex Concentrate (PCC) and intravenous (IV) Vitamin K 5mg for patients with major bleeding, 1-3mg of Vitamin K intravenously for those with minor bleeding and 1-5mg of Vitamin K orally for patients with INR >8 and who have no signs of bleeding.
Aims: The aim of this audit was to compare our hospital's performance against the above guidelines.
Methods: A total of 76 patients admitted between 01/08/2015-31/01/2016 were analysed retrospectively.
Results: There were 103 incidents with INR level 5-8 and 24 with INR >8 in these 76 inpatients. Bleeding was documented in 18/127 cases, which included 6 incidents of major and 12 incidents of minor bleeding. In major bleeding, warfarin was withheld and Vitamin K administered. However, 4/6 (66.7%) of these patients got a dose different to 5mg advocated. Also, PCC was prescribed in only 50% of these patients. While 9/12 (75%) patients with minor bleeding received Vitamin K, only 3 of these 9 patients received the recommended dose of 1-3mg IV. Vitamin K was unnecessarily given to 9/83 (10.8%) non-bleeders with an INR between 5-8. Additionally, the recommended dose and route of administration of Vitamin K 1-5mg PO was followed only in 7/16 (44%) of non-bleeders with INR >8.
Summary/Conclusions: Our audit highlighted that there is less than 100% compliance in the recommended dose and route of vitamin K administration. A flowchart containing the guidelines will be designed to improve the management of high INR. To increase the awareness of this issue, teaching sessions for junior doctors and nursing staff are planned. A re-audit will be conducted once these steps are in place.

E979

NOVEL AND RECURRENT F7 MUTATIONS IN KOREAN PATIENTS WITH COAGULATION FACTOR VII DEFICIENCY
H. Kim[1,*], K.-Y. Yoo[2], K.-O. Lee[3], S.-H. Kim[1], H.-J. Kim[1]
[1]Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, [2]Korea Hemophilia Foundation, [3]Samsung biomedical Research Institute, Seoul, Korea, Republic Of

Background: Coagulation factor VII deficiency is one of rare hereditary bleeding disorders with relatively limited clinical and genetic data.
Aims: This study aimed to characterize *F7* gene mutational patterns of Korean patients with coagulation Factor VII deficiency including their clinical and laboratory variability.
Methods: *F7* gene mutations of total 16 unrelated Korean patients with Factor VII deficiency were identified by direct sequencing analyses of all exons and flanking intronic sequences. Variants were assigned according to the recently released criteria of 2015 ACMG standards and guidelines.
Results: A total of 14 mutations (pathogenic or likely pathogenic) were detected including four novel mutations (Glu66Lys, c.681+3A >T, Glu66Alafs, Ile290del). Six (38%) patients have 2 mutant alleles and three mutations were recurrently identified. The most frequent mutation detected in this study was Cys389Gly detected in 37% (11/30) patients, validating the data of our previous patient cohort.
Summary/Conclusions: Correlation of genetic data with coagulation laboratory and clinical findings suggested the presence of modifiers, which warrants further investigation in a larger cohort of patient for better clinical prediction and management in this rare bleeding disorder.

UTILITY OF CD157 IN A FLAER BASED SINGLE TUBE FIVE COLOR COMBINATION FOR SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE

K. Rahman[1,*], R. Gupta[1], S. Harankhedkar[1], T. Gupta[1], M. Sarkar[1], S. Nityanand[1]
[1]Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Fluorescent Aerolysin (FLAER) based flow cytometric analysis of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.
Aims: The objective of this study was to analyse the utility and advantage of CD157 in the PNH screening along with its ability to replace CD24 and CD14.
Methods: Our routine protocol for PNH screening included single tube six color antibody cocktail in following combination: FLAER-AF488, CD24-PE, CD15-PerCPCy5.5, CD14-PeCy7, CD64-APC, CD45-APC H7. We assessed the utility of single tube 5 color combination of FLAER-AF488, CD157-PE, CD15-PerCPCy5.5, CD64-APC, CD45-APCH7 for PNH screening and compared the results with the routinely used 6 color panel. Laboratory cutoff for CD157 was defined by running 10 samples from healthy individuals. Sensitivity analysis was assessed in spiking experiments by diluting a PNH positive sample with large clone size in a serial 10 fold dilution. Inter assay and intra assay precision analysis was done by running samples in triplicates across different clone size range and calculating the coefficeint of variance (CV). Correlation of PNH clone size obtained from CD24/CD14 and CD157 was assessed by analysing a total of 30 samples across a wide range of PNH clone size (0.06-97.3%).
Results: CD157 was sensitive at the level of 10^{-4} and better. Frequency of cells with PNH phenotype in normal samples were found to be <0.002%. The CVs of intra-/interassay precision analysis ranged from 0.9/2.6% to 3.2/4.64% for granulocytes and 1.9/2.5 to 5.3/8.9% for monocytes. The PNH clone size as obtained by CD157 based analysis was highly comparable to those obtained by CD24/CD14 based assay (R^2>0.993). CD157 was found much better than CD24/CD14 in identifying the type II PNH clones. There was no false positive or false negative result. The cost of analysis was found to be approximately 15% lesser than the routinely used 6 color assay.

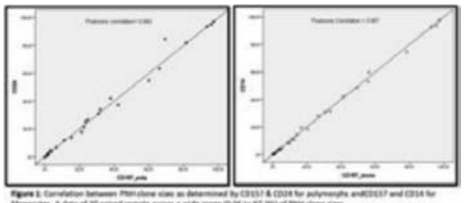

Figure 1.

Summary/Conclusions: CD157 is a robust, reliable and potentially useful universal marker for PNH screening. Its inclusion in a single tube five color FLAER based panel is a cost effective approach which is ready to replace CD24/CD14 from routine PNH screening.

E982

IMMUNOPHENOTYPIC DYSPLASTIC FEATURES IN PATIENTS WITH APLASTIC ANEMIA

Y. Davydova[1,*], E. Parovichnikova[1], I. Galtseva[1], E. Mikhaylova[1], N. Kapranov[1], A. Kohno[1], L. Kuzmina[1], V. Troitskaya[1], Z. Fidarova[1], T. Moiseeva[1], V. Savchenko[1]
[1]Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Multicolor flow cytometry (MFC) of bone marrow (BM) is a promising additional approach to the diagnosis of myelodysplastic syndromes (MDS). Aplastic anemia (AA) as MDS characterizes by cytopenias and dysplastic features in BM by morphology are absent. It is well known that up to 15% of AA transformed in MDS over time. It is possible to suggest that in some cases of AA immunophenotypic abnormalities can also be identified.
Aims: To study and compare the presence of dysplastic features by MFC in AA and MDS without excess of blasts.
Methods: The study included 14 patients with AA (8m, 6f, median age 33), 28 patients with MDS *de novo* without excess of blasts by morphology (13m, 15f, median age 59). MDS group included 3 patients with 5q-syndrome, 4 - RCUD, 3 - RARS, 18 - RCMD. 20 patients with cytopenias constituted the control group (4m, 16f, median age 42) due to B-12 deficiency anemia, iron-deficiency anemia, Fanconi anemia, hemolytic anemia, β-thalassemia, ITP, hepatitis C, multiple myeloma, Burkitt's lymphoma. BM of 33 healthy donors were analyzed for the reference values. MFC was performed according to International LeukemiaNet by 6-color cytometer BD FACSCanto II. We enumerated the proportion of CD34+ myeloid cells from CD45+ cells (normally <2%), the proportion of CD19+ (B-cell progenitors) from CD34+ cells (normally >5%), the expression of CD34, CD45, CD117, CD7, CD56 on CD34+ myeloblasts. Among granulocytes we analyzed: their proportion, granularity, CD14, CD64, CD10, CD56 expression and patterns CD16vsCD13, CD16vsCD11b, CD13vsCD11b. Among of monocytes we measured: their proportion, CD64, CD56 expression and analyze patterns CD14vsCD36, CD11bvsCD13, CD11bvsHLA-DR. The final MFC conclusion was done by scale Ogata/Wells (van de Loosdrecht, 2013): A - does not correspond to MDS; B - reveales some features which commonly appears in MDS; C - results are consistent with MDS.
Results: Among MDS patients without excess of blasts assessment "B" and "C" scores were obtained in 78.6% (sensitivity). Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 - in 42.9%. The most common abnormalities were: increased CD56 (53.6%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased proportion (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA were assessed as "A", 21.4% (n=3) - "B" and 14.3% (n=2) - "C". In cases with "C" abnormal expression of CD117 and expression of CD56 on CD34+ cells were seen. AA patients with "B" and "C" showed increase expression of CD56, CD64 and decrease CD10 expression on granulocytes. Abnormal patterns were less common than in MDS patients. The increased proportion and CD56 expression in monocytes were more frequent than in MDS patients.
All patients not diagnosed with AA, MDS were assessed as "A" (specificity-100%). But some MFC abnormalities were found in them: abnormal expression of CD34 (35%) and CD45 (30%) on CD34+ myeloblasts, and increased CD64 expression (20%) on granulocytes (pic.).

Table 1.

Diagnosis	MDS		not AA, not MDS		AA	
number	28		20		14	
A by Ogata/Wells	6	(21.4%)	20	(100.0%)	9	(64.3%)
B by Ogata/Wells	5	(17.9%)	0	(0.0%)	3	(21.4%)
C by Ogata/Wells	17	(60.7%)	0	(0.0%)	2	(14.3%)
CD34+ cells						
%CD34+ myeloblasts ≥2%	10	(35.7%)	1	(5.0%)	0	(0.0%)
%CD34+/19+ <5%	13	(46.4%)	3	(15.0%)	5	(35.7%)
abnormal expression CD45	15	(53.6%)	6	(30.0%)	4	(28.9%)
abnormal expression CD34	7	(25.0%)	7	(35.0%)	1	(7.1%)
abnormal expression CD117	21	(75.0%)	3	(15.0%)	1	(7.1%)
increased CD56	12	(42.9%)	2	(10.0%)	2	(14.3%)
increased CD7	12	(42.9%)	1	(5.0%)	1	(7.1%)
Granulocytes						
decreased %	15	(53.6%)	6	(30.0%)	4	(28.6%)
low granularity	10	(35.7%)	0	(0%)	1	(7.1%)
increased CD64	6	(21.4%)	4	(20.0%)	9	(64.3%)
increased CD56	15	(53.6%)	2	(10.0%)	5	(35.7%)
decreased CD10	3	(10.7%)	0	(0.0%)	1	(7.1%)
abnormal CD13 vs CD16	11	(39.3%)	1	(5.0%)	4	(28.6%)
abnormal CD13 vs CD11b	11	(39.3%)	1	(5.0%)	2	(14.3%)
abnormal CD16 vs CD11b	6	(21.4%)	0	(0%)	3	(21.4%)
Monocytes						
decreased %	1	(3.6%)	1	(5.0%)	0	(0.0%)
increased %	6	(21.4%)	0	(0.0%)	7	(50.0%)
increased CD64	3	(10.7%)	1	(5.0%)	4	(28.6%)
increased CD56	6	(21.4%)	0	(0.0%)	6	(42.3%)
abnormal HLA-DR vs CD11b	8	(28.6%)	2	(10.0%)	1	(7.1%)
abnormal CD13 vs CD11b	8	(28.6%)	1	(5.0%)	1	(7.1%)
abnormal CD36 vs CD14	5	(17.9%)	0	(0.0%)	2	(14.3%)

Summary/Conclusions: Flow cytometry MDS study with Ogata/Wells scale has a high sensitivity and specificity. Immunophenotypic abnormalities characterizing dysplastic features can also be found in AA patients up to 35% of cases. Increased expression of CD56 on CD34+ myeloblasts, granulocytes and monocytes is commonly found in AA patients. Perhaps the appearance of MFC dysplastic features foreshadows the MDS-transformation of AA, but requires further prospective studies.

Background: Patients with PNH often need surgery due to disease-related complications. However, surgery, anesthesia, and possible surgical complications, including inflammation and acidosis, can trigger complement activation, making surgery an important risk factor for hemolysis (Ando K, *et al.* Ann Hematol 2012;91:1987-8; van Bijnen ST, *et al.* Eur J Haematol 2011;87:376-8).
Aims: Here we report data on the clinical management and treatment results of patients with PNH undergoing surgery.
Methods: We collected data on 14 surgical interventions of 11 patients (8 males; age, 25-76 years). All patients had a high prevalence of PNH clone cells (55-99% in PMN) and were receiving eculizumab (ECU). Types of surgery were: 6 laparoscopic cholecystectomies, a transjugular intrahepatic portosystemic shunt, a distal splenorenal shunt, a laparoscopic Achilles allograft ligamentoplasty, a gastrectomy, an emergency appendectomy, and 3 urologic interventions. Ten patients received ECU 900mg, while one (patient E, surgery 6) received 1200mg since he had developed hemolysis at a previous surgical intervention (surgery 5). In two cases (patient G, surgery 8; patient H surgery 11), an additional dose of ECU was administered before surgery. Patient H (surgery 11) had developed hemolysis at previous surgical interventions (surgeries 9 and 10). In most cases, either the date of the ECU dose was taken into account when scheduling surgery or the ECU dose was moved forward to coincide with the date of surgery. The time between the last ECU dose and surgery was normally one day (range, 1-8).
Results: In nine cases, transfusions were required due to hemorrhagic complications. Patient I (surgery 12) had a thrombotic event leading to acute myocardial infarction one week after surgery. Increased hemolysis was observed (increased LDH and/or presence of hemoglobinuria) in five cases (patients E, H, I and K; surgeries 5, 9, 10, 12 and 14) during the week following surgery. Two of these patients (patients E and H) later underwent additional surgery (surgery 6, and surgeries 10 and 11, respectively). The pre-surgical ECU dose was increased in surgery 6 (patient E) and an extra dose was administrated in surgery 11 (patient H) and no hemolysis was observed. (See Table 1).

Table 1.

Surgery	Patient	Patient Age at Surgery	Surgical Procedure	Pre-surgical ECU Dose	Days between last ECU Dose and Surgery	Transfusion	Post-surgical Increase in Hemolysis
1	A	56	laparoscopic cholecystectomy	900mg	2	2 Packed red blood cells (PRBCs)	no
2	B	58	laparoscopic cholecystectomy	900mg	1	2 PRBCs	no
3	C	38	portosystemic shunt	900mg	7	4 PRBCs	no
4	D	46	distal splenorenal shunt	900mg	1	4 PRBCs + 1 platelet pool	no
5	E	49	ligamentoplasty	900mg	1	no	yes (1 week after surgery)
6	E	50	laparoscopic cholecystectomy	1200mg	1	no	no
7	F	76	laparoscopic cholecystectomy	900mg	7	no	no
8	G	67	gastrectomy	900mg (additional dose)	1	no	no
9	H	69	left ureterorrenoscopy and lithotripsy with placement of double J stent	900mg	4	3 PRBCs	yes
10	H	69	replacement of double J stent	900mg	8	3 PRBCs	yes
11	H	69	Holmium laser lithotripsy with placement of double J stent	900mg (additional dose)	1	1 PRBCs	no
12	I	63	emergency appendectomy	900mg	2	4 PRBCs	yes
13	J	60	laparoscopic cholecystectomy	900mg	5	no	no
14	K	25	laparoscopic cholecystectomy	900mg	1	2 PRBCs	yes

Summary/Conclusions: Our findings lead us to recommend to perform the intervention within 24 hours of the administration of Ecu in programmed surgery for which it is necessary to program the dose. While in urgent surgical interventions put a new dose on the day of the intervention independently of the previous dose. Also the normal ECU dose could be increased or an extra dose be administered in order to minimize the risk of hemolysis in high-risk patients or in those with a previous history of surgery-related hemolysis.

E984

EFFICACY OF ECULIZUMAB IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) PATIENTS WITH OR WITHOUT APLASTIC ANEMIA; PROSPECTIVE STUDY OF KOREAN PNH COHORT

C.W. Choi[1], J.H. Jang[2,*], J.S. Kim[3], D.-Y. Jo[4], J.-H. Lee[5], S.-H. Kim[6], Y.-K. Kim[7], J.-H. Won[8], J.S. Chung[9], H. Kim[10], J.H. Lee[11], M.K. Kim[12], H.-S. Eom[13], S.Y. Hyun[14], J.-A. Kim[15], J.W. Lee[16]

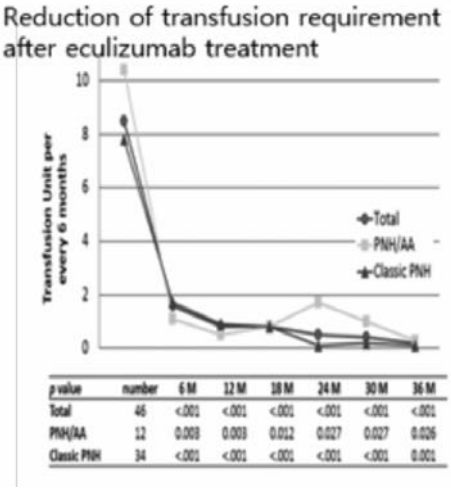
Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a hematopoietic stem cell disease characterized by the intravascular lysis of red blood cells. PNH patients often have underlying bone marrow failure (BMF), with aplastic anemia (AA) as the most frequently associated type. Eculizumab, a humanized monoclonal antibody that binds specifically to human complement protein C5, has been used in Korea since 2012.
Aims: The purpose of this study was to determine whether eculizumab-treated patients show clinical benefit and reduced risk of complications regardless of concomitant AA in a Korean population.
Methods: Forty-six PNH patients ≥18 years of age diagnosed by flow cytometry and treated with eculizumab for more than 6 months were analyzed in the prospective Korean PNH registry. Patients were categorized into two groups: PNH patients with concurrent AA (PNH/AA) and without (classic PNH). Patients with severe AA/PNH were excluded. Biochemical indicators of intravascular hemolysis, hematological laboratory values, transfusion requirement, and PNH-associated complications assessed by the treating physician were reported every 6 months after enrollment.



p value	number	6 M	12 M	18 M	24 M	30 M	36 M
Total	46	<.001	<.001	<.001	<.001	<.001	<.001
PNH/AA	12	0.008	0.008	0.012	0.027	0.027	0.026
Classic PNH	34	<.001	<.001	<.001	<.001	<.001	0.001

Figure 1.

Results: The median age of the study population was 49 years (range, 18-73 years) at eculizumab initiation and the median duration of eculizumab treatment was 34 months (range, 6-44 months). Median LDH fold x upper limit of normal was 7.29 (range 2.4-23.7) and GPI-deficient granulocytes was 92.8% (range, 15.7-100%) at the time of eculizumab treatment. PNH-related signs and symptoms were thromboembolism (TE, n=19), renal failure (n=20), pulmonary hypertension (n=5), and severe/recurrent abdominal pain requiring opioids (n=17). Of 46 total patients, 12 (26%) were classified as having PNH/AA and 34 with classic PNH. There were no substantial differences in laboratory findings, transfusion requirement, or clinical signs and symptoms at baseline between the two groups. Treatment with eculizumab induced a rapid inhibition of hemolysis. At the time of 6 month follow-up, LDH level decreased to near normal levels in all patients and this effect was maintained until 36 months follow-up regardless of concomitant AA. Mean hemoglobin level significantly increased from the first 6 months of eculizumab treatment, and the effect (hemoglobin above 10 g/dL) was sustained throughout 36 months in both groups. Transfusion-independence was achieved by 54.3% within the first 6 months of treatment and 86.4% by the last 36 months (83.3% in PNH/AA *vs* 87.5% in classic PNH). The mean number of RBC units transfused was significantly reduced from 8.5 units during the previous 6 months to 1.6 units for the first 6 months in total PNH patients (Fig). There were no significant differences in clinical outcomes (ie, LDH and transfusion unit per every 6 months) with eculizumab between the two groups. All TE (n=19) patients in whom 6 received concomitant anticoagulation therapy were resolved on the eculizumab; one classic PNH patient had recurrence of TE at the same site after discontinuation of anticoagulation therapy while on eculizumab. Among 9 patients who had baseline eGFR less than 60 ml/min/1.73m^2, 5 patients (56%) showed improvement of eGFR during the eculizumab treatment and 4 patients stabilized eGFR.

Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.

DIAGNOSIS AND FOLLOW-UP OF THE CLONES OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA BY FLOW CYTOMETRY

S. Oukid[1,*], S. Taoussi[1], N. Rekab[1], M.T. Abad[1]
[1]Hematoloy, EHS ELCC CAC, Blida, Algeria

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare chronic disease associated with a clonal expansion of one or several hematopoietic stem cells carrying acquired somatic mutations of PIG-A gene resulting in GPI-AP deficient blood cells and great susceptibility to complement mediated cell lysis. Diagnostis of PNH is of importance and flow cytometry (FC) is a required tool for this. We report 33 cases of PNH diagnosed and monitored by FC.
Aims: To show the interest of flow cytometry for the diagnosis and follow-up of PNH clones in some risky haemopathies.
Methods: A PNH clone has been researched in 234 patients since August 2009 to January 2017. The PNH clone was investigated for bone marrow aplasia with or without haemolysis, regenerative hemolytic anemia with negative direct coombs test (DCT), myelodysplasia (MDS), unexplained cytopenia and thrombosis. The search for the PNH clone by FC is based on the analysis of the following monoclonal antibodies: Flear and CD59 with gating on CD45 for neutrophils, Flear and CD14 with gating on CD64 for monocytes and CD59 with gating on Glycophorin A for red blood cells. We judged that the patient has an PNH clone when the deficiency is >05% on at least two markers highlighted on two different lines. FC surveillance is provided in the absence of a deficit or in the case of a very moderate or single-line deficit.
Results: Out of 234 cases analyzed, 201 cases (85%) showed absence of PNH clone and 33 cases (14%) had a PNH clone. There are 14 women and 19 men; Sex ratio (M/F) = 1.35, mean age = 42.27 years (17-73). Among patients that should be screened for positive PNH clone we have bone marrow failure: 25 positive (21,9%) of 114 cases screened, hemolytic anemia with negative direct coombs test: 4 positive/63 cases (6.34%), thrombosis: 2 positive/28 (7.14%), one negative case of AML2, myelodysplasia with 02 (11.2%) positive/18 cases and cytopenias: 0 positive/13 cases. The types of PNH was type II in 3 cases (9%), type III in 24 cases (72.8%) and mixed deficits in 6 cases (18.2%). The mean degree of CD59 deficiency was 29.4% (5-82) on red blood cells 48.21% (5-95) on neutrophil (N); the mean degree of Flear was 55.33% (6-99) on N in 22 cases ; the mean degree of CD14 deficiency on monocytes was 44% (7-97) in 17 cases, the mean degree of Flear (8 cases) was 51.8% (12.9-92). During surveillance, PNH clone appeared in 02 cases and clone size increase in 08 cases (initially less than 2%) and in one case the clone doubled in size from 54% to 98% and 6 months after the patient developed extensive thrombosis. In 44 cases, a moderate deficiency <5% was noted on a single line either N or red blood cells, thus monitoring by FC.
Summary/Conclusions: In our study the clone PNH was noted in 11.2% of cases of MDS which joins the literature were the rate is 10 to 23%. (1). In the group where a moderate deficit was observed, there are no biological signs of haemolysis ; in these cases, the indication of a follow-up of the size of the PNH clone is then necessary and must include a haemolysis report repeated with LDH assay; this is verified in our study since in 8 cases of increase in the size of the clone a thrombosis developed in one case. The follow-up of clone sizes is important given that there are 8 cases of increase in clone size, and in 01 case the increase was accompanied by thrombosis. This interest was confirmed by the study of B. Höchsmann who demonstrated in 155 cases of followed PNH, a significant increase of the clone in 28% of the cases and in 9% of the cases a new clone appeared. (2). The application of flow cytometry enabled us to make the diagnosis and to determine the phenotypic profile of PNH clones and to specify their sizes as well as to follow up the patients.

E986

ASSOCIATION OF T-, B-, NK AND NKT CELLS WITH THE DURATION, COMPLETENESS AND OTHER CHARACTERISTICS OF REMISSION IN PATIENTS WITH APLASTIC ANEMIA

O. Rozanova[1,*], T. Glazanova[1], E. Shilova[2], L. Bubnova[1]
[1]Laboratory of Immunohematology, [2]Clinical Department of Chemotherapy of Hemoblastoses, Russian Research Institute of Hematology and Transfusiology, Saint-Petesburg, Russian Federation

Background: Immune-mediated dysregulation of hemopoiesis is the basis for pathogenesis of aplastic anemia (AA). Dysbalance of T cell subsets, especially Th1 and Th2 and produced by them cytokines serves as a possible mechanism of this phenomenon. It is suggested, that NK-T cells play an important role in regulation of Th1:Th2 balance. The role of NK-T cells in development of aplasia of hemoiesis in AA now is broadly studied. Nevertheless, up to this moment, the features of balance of T lymphocyte subsets, and, especially NK-T cells during stable and prolonged remission are not characterized yet.
Aims: To evaluate the association of T-, B-, NK и NK-T cell levels of AA patients with the duration of remission, its completeness, duration of period free of immunosuppressive therapy (IST) and the size of PNH-clone.
Methods: The studied group included 36 patients with AA in remission, reference group – 20 patients with primary diagnosed AA. Level of T-, B-, NK and NK-T cells in peripheral blood (PB) and bone marrow (BM) was evaluated using 5-color flow cytometry (Beckman Coulter, FC-500).
Results: Group of AA patients in remission was divided into subgroups in four variants: 1) according to the remission duration (<12 months, 12-24 months, 24-36 months, >36 months); 2) completeness of remission: partial (PR) and complete (CR); 3) duration of IST-free period (<1 year, ≥1 year); 4) PNH-clone size (0,1-1%, 1-10%, >10%). Levels of T-, B- and NK cells in AA patients with remission varied broadly in different subgroups, but there were not revealed any clear tendency of their dynamics in all assigned subgroups, except for NK-T cells. In primary AA patients the level of NK-T cells in PB and BM exceeded normal level 1,8- and 2,2-fold, respectively. In remission lasting less then 12 months NK-T cell level decreased significantly; then, along with increase of remission duration (24-36 months), it normalised, and in patients with remission ≥36 months it significantly decreased both in PB and BM (data presented in **table 1**). In patients with PR, as compared with primary AA patients, NK-T cells decreased 2,8- and 1,9-fold, respectively, and further in CR this tendency persisted. Duration of IST-free period less than 1 year and ≥1 year was also accompanied by a significant and stable decrease of NK-T cells in PB and BM. It is known that PNH-clone presence is a favourable factor for treatment response of AA patients. Therefore, it was of interest to study the association of NK-T cell level in AA remission with the size of PNH-clone. In subgroup with small PNH-clone (0,1-1%) NK-T cell level was decreased as compared to primary AA patients, and it significantly decreased further along with growth of PNH-clone size.

Table 1. NK-T cell level (%) in patients with AA in remission according to subgroups.

Group	Primary AA	Remission duration (months) (1)				Remission completeness (2)		IST-free period (years) (3)		Size of PNH-clone (4)		
		<12	12-24	24-36	>36	PR	CR	< 1	≥1 y.	0,1-1%	1-10%	>10%
PB	8,6	2,4	3,9	4,9	1,8	3,1	2,9	2,7	1,7	3,8	1,1	1,7
BM	10,5	4,9	4,3	n.d.	3,4	5,6	4,3	6,4	4,0	5,7	5,4	2,9

Summary/Conclusions: Thus, in patients with AA the decrease of NK-T cell level was observed along with recovery of hemopoiesis in all the subgroup variants. Previously we have shown that the decrease of NK-T cells accompanies the decrease of TNFα and increase of IL-4. This pattern, taking into consideration our earlier obtained data, may be the evidence of the role of NK-T-cells in regulation of balance Th1:Th2 and produced by them cytokines.

E987

A NOVEL DUAL-REAGENT SINGLE TUBE FLOW CYTOMETRIC ASSAY TO SCREEN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

K. Bommannan[1,*], M.U.S. Sachdeva [1], J. Ahluwalia[1], P. Bose[1], N. Varma[1]
[1]Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired hematopoietic stem cell disorder resulting from loss of membrane-bound glycosyl phosphatidy linositol (GPI) anchor protein. The disease is characterized by heterogeneous clinical phenotypes including intravascular hemolysis, cytopenia(s), bone marrow hypoplasia and atypical site thrombosis. Screening guidelines recommend documentation of the lack of at least two GPI-liked antigens on at least two cell lineages. Alexa fluor 488 conjugated fluorescent Aerolysin (FLAER-AF488) has become a mandatory component in FCM based PNH assays.
Aims: We have analyzed the feasibility of a novel dual-reagent assay for a simplified, single tube, cost-effective approach for PNH screening.
Methods: EDTA anti-coagulated peripheral blood of patients referred to department of Hematology with clinical suspicion of classical-PNH/ aplastic anemia, was tested with a single tube panel of FLAER-AF488/CD33APC. Simultaneously, the routine two tube flow cytometry assay (established sensitivity of 0.1%) used in our lab for PNH screening (FLAER/ CD15/ CD24 for granulocytes and FLAER/CD33/CD14 for monocytes) was performed in the same sample. Each tube was run till a minimum of 50,000 granulocytes were acquired or till the tube ran dry. A cluster of at least 20 FLAER negative events was considered for reporting PNH-clone positivity in both granulocytes and monocytes. The granulocyte and monocyte PNH positivity and the respective clone sizes detected by both the strategies were compared.
Results: A total of 33 patients and 7 healthy controls were analyzed by both dual-reagent and conventional strategies. Among the thirty-three patients, twelve patients concurrently showed the presence of PNH clones by both methods (36%). The rest twenty-one patients were negative for PNH clones in granulocytes and monocytes by both strategies, indicating complete concordance at a sensitivity of 0.2% (Chi Square p=0.000). Of the PNH positive cases, the mean PNH clone sizes among the granulocytes by dual-reagent and conven-

tional methods were 3.79% (range, 0.2-18.2) and 3.60% (range, 0.1-18.6), respectively. The mean PNH clone sizes among the monocytes by dual-reagent and conventional methods were 7.30% (range 0.2-29.4) and 7.32% (range 0.1-28.8), respectively. There was no significant difference in the granulocyte and monocyte PNH clone sizes determined by both the methodologies (p=0.000). There were significant correlations between the granulocyte PNH clone sizes (Pearson's r=0.993, p=0.000) and the monocyte PNH clone sizes (Pearson's r=0.991, p=0.000) detected by both the analysis strategies.
Summary/Conclusions: This pilot study demonstrates the practical feasibility of a simple, cost-effective and widely applicable dual-reagent, single tube PNH-screening assay at a sensitivity of 0.2%.The study needs to recruit patients of various hematological disorders besides healthy controls, and although seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

E988

TREATMENT OF REFRACTORY APLASTIC ANEMIA WITH ELTROMBOPAG: EXPERIENCE OF A CENTER
M. Gomes[1,*], M.J. Teles[2], F. Ferreira[1], J.E. Guimarães[1]
[1]Clinical Hematology, [2]Clinical Pathology, São João Hospital Centre, Porto, Portugal

Background: Eltrombopag, a thrombopoietin receptor agonist, was approved in 2008 for the treatment of immune thrombocytopenic purpura. More recently, benefits demonstrated in the proliferation and maintenance of hematopoietic stem and progenitor cells (HSTC) led to its use and approval in the treatment of severe aplastic anemia (AA) refractory to immunossupressive therapy.
Aims: In this report, we evaluated response to eltrombopag in patients with refractory AA and associated side effects.
Methods: Retrospective analysis of six patients with a diagnosis of aplastic anemia and thrombocytopenia (platelet count ≤30.000/uL), refractory to imunossupressive therapy and ineligible for allotransplant, treated with eltrombopag. Patients characteristics, response, clinical evolution and adverse effects were evaluated.
Results: Four patients were female and median age at diagnosis was 66 years (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and danazol (1). Treatment with eltrombopag was associated to cyclosporine in four patients; two cases had chronic renal failure and consequent contraindication to cyclosporine. The median duration of treatment with eltrombopag at the time of this analysis was 7 months (3-12). At 3 months, all patients had platelet counts >30.000/uL (median increase, 16.500/uL). Five patients improved hemoglobin levels (median increase, 2.2g/dL); 3 of them were previously dependent on red cell transfusions, and no longer needed transfusions. Four patients increased neutrophil counts (median increase, 1110/uL). All but one patient received a maximum dose of 150mg per day. Only one patient needed temporary discontinuation due to hepatic abnormalities, that were rapidly resolved. One other patient had mild elevation of liver enzyme levels. No other relevant side effects occurred.
Summary/Conclusions: Treatment with eltrombopag was associated with hematologic response of one or more hematopoietic lineage, independence of blood transfusions and improved quality of life of patients with refractory severe AA. Except for infrequent and reversible hepatic abnormalities, tolerability was excellent. Thus, eltrombopag might be used in situations where other measures have failed in patients who have no indication for allogeneic stem cell transplant. A caution, however, should be taken on the risk for clonal evolution that should be carefully screened and surveilled.

Chronic lymphocytic leukemia and related disorders - Biology

E989

DECREASED EXPRESSION OF ADHESION MOLECULES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS OF PATIENTS TREATED WITH IBRUTINIB
A. Guarini[1,2,*], M.S. De Propris[1], M.L. Milani[1], S. Intoppa[1], S. Faraone[1], N. Peragine[1], P. Mariglia[1], M.C. Puzzolo[1], F.R. Mauro[1], I. Del Giudice[1], R. Foà[1]
[1]Department of Cellular Biotechnologies and Hematology, [2]Department of Molecular Medicine, Hematology, Sapienza University, Rome, Italy

Background: The B-cell receptor (BCR) pathway in CLL plays a well recognized role in the onset and progression of the disease and the resulting development of mechanism-driven drugs is revolutionizing the therapeutic management. Ibrutinib is a BTK inhibitor that plays an important role in the BCR pathway and induces several alterations in CLL cells.
Aims: The modulation of the expression of adhesion molecules on the surface of CLL cells from patients treated with ibrutinib has been evaluated to analyze the effect of treatment on the relationship between the microenvironment, that promotes cell survival and proliferation, and the leukemic cells with the consequent cell mobilization and increased drug exposure.
Methods: In a cohort of 101 CLL patients treated with ibrutinib (420mg/die) and rituximab (375mg/m^2/week) in the GIMEMA LLC1114 trial, we evaluated, before and after 15 days of therapy, the surface expression on leukemic cells of several adhesion molecules. In detail, using 8 color antibody combinations (all from Becton Dickinson, BD, San José, CA) we evaluated the MIF expression (using the FACSCanto II, BD) of CD11a, CD18, CD38, CD40, CD43, CD44, CD49d, CD62L, CD69, CD80, CD81, CD86, CD154, CD184, CD185 on CD5/CD19+ leukemic cells.
Results: The number of CD5/CD19+ did not increase after 15 days of treatment (52.8±58.8 *vs* 53.4±51.5 x 10^9/L; p=0.36) probably because of the concomitant rituximab administration, which 'masks' the mobilization effect induced by ibrutinib. We observed a significant down-modulation of CD62L (461±435 *vs* 171±146; p<0.0001), a molecule (L-selectin) that has been reported as the key factor controlling the binding of CLL cells to the endothelial walls in vivo. CD69 expression resulted also significantly decreased (744±784 *vs* 438±716; p<0.0041), is expressed on CLL cells in the tissue microenvironment, both in the bone marrow and in lymph nodes. We observed the significant down-modulation of the expression of CD43 (3285±2282 *vs* 2515±1826; p<0.0063); this antigen is utilized in CLL for the detection of minimal residual disease (MRD) and does therefore not seem a reliable marker in patients treated with ibrutinib. On the contrary, CD81 expression, another antigen utilized for MRD detection, resulted unchanged after 15 days of treatment. CD185 expression was significantly decreased (1502±1327 *vs* 804±687; p<0.001), while we unexpectedly observed the up-modulation of CD184 (2244±2022 *vs* 3182±1877; p<0.003); both antigens participate in the BTK signaling pathway. CD40, that interacts with activated CD4+ T cells, resulted down-modulated (722±467 *vs* 395±262; p<0.0001). CD38 and CD49d, when expressed in >20% of the leukemic cells, resulted significantly (p<0.028 and p<0.021) down-modulated: both molecules have a role in the crosstalk between the leukemic cells and the microenvironment. No significant changes were detected in the expression of CD11a, CD18, CD44, CD80, CD86 and CD154.
Summary/Conclusions: Within an ancillary biologic study of the GIMEMA LLC1114 protocol we observed a significant down-modulation in the expression of several adhesion molecules on the surface of CLL cells of patients treated with ibrutinib. Since these molecules promote the binding of the leukemic cells with the microenvironment, these results help to elucidate the mobilization process of CLL cells from the different compartments observed with ibrutinib and support its progressive efficacy over time in controlling the disease. A follow-up clinical analysis will define a possible correlation between these findings and response to treatment.

Background: The gene expression profile of chronic lymphocytic leukemia (CLL) cells revealed a homogeneous phenotype related to memory B cells accompanied by an aberrant expression of several proteins. For example, lipoprotein lipase (LPL), typically expressed in adipocytes, is readily detected in CLL cells. However, unlike their normal counterparts which are resting cells, CLL cells do proliferate. What energy source CLL cells use and which metabolic pathway they recruit is currently unknown. Because the gene expression profile of CLL cells is skewed towards that of adipocytes, and because they proliferate at similar rates, we hypothesized that like adipocytes CLL cells utilize free fatty acids (FFA).
Aims: (A) Determine whether CLL cells are capable of utilizing FFA for energy production. (B) Determine whether lipid metabolism in CLL is LPL dependent. (C) Determine why LPL is aberrantly expressed in CLL cells.
Methods: Peripheral blood (PB) and bone-marrow derived lymphocytes were obtained from previously untreated patients with CLL. Imaging of CLL cells was done by electron microscopy, and PB lymphocytes were stained for Oil red O. Confocal microscopy studies helped in determining the cellular localization of LPL. To study the capacity of CLL cells to utilize FFA we developed an assay that measured the oxygen concentration in the sera of cultured CLL cells prior to and after adding FFA. In addition we measured the oxygen consumption of CLL cells derived from ibrutinib-treated patients. We used chromatin immunoprecipitation (CHIIP) and luciferase assays to study the binding of STAT3 to the *LPL* promoter.
Results: To study whether CLL cells are capable of utilizing FFA we cultured freshly isolated CLL cells from 20 patients and measured the concentration of cultured media-dissolved O_2 (dO_2) prior to and after adding FFA, assuming that if the cells oxidize the acid, dO_2 levels will drop. Indeed, after 48 hours incubation with FFA dO_2 levels were markedly reduced as compared with the dO_2 media levels of CLL cell incubated without FFA. Remarkably, unlike cultured CLL cells, dO_2 media levels of cultured normal B cells did not changed. Intriguingly, the levels of dO_2 remained unchanged if CLL cells were incubated in the presence of FFA and ibrutinib. Similarly, the dO_2 levels of CLL cells obtained from ibrutinib-treated patients remained constant, suggesting that ibrutinib disrupts the capacity of CLL cells to utilize FFA. Oil Red O staining of CLL bone marrow smears detected lipid deposits and electron microscopy confirmed the presence of lipid vacuoles in the cytoplasm of peripheral blood CLL cells but not in normal B cells, suggesting that like adipocytes, CLL cells store lipids in intracytoplasmic lipid vacuoles. Similar to adipocytes CLL cells express LPL which mediates the uptake of lipid particles into the cells and catalyze the hydrolysis of triglycerides into FFAs. Indeed, we detected LPL in the cell membrane and in the cytoplasm of CLL cells. Furthermore, using small interfering RNA (siRNA) we knocked-down LPL mRNA levels and found that LPL-siRNA reduced the capacity of CLL cells to utilize FFA, suggesting that the lipid metabolism in CLL is LPL-dependent. Because STAT3 is constitutively active in CLL cells, and because the LPL gene harbors STAT3 binding sites, we sought to determine whether STAT3 activates the LPL gene. Indeed, transfection of luciferase reporter gene constructs driven by LPL promoter fragments into MM1 cells revealed that STAT3 activates the LPL promoter. In addition, ChIP confirmed that STAT3 binds to the LPL promoter. Furthermore, transfection of CLL cells with STAT3-shRNA downregulated LPL transcripts and protein levels, confirming that STAT3 activates the LPL gene.
Summary/Conclusions: Our data suggest that CLL cells undergo metabolic reprograming and use strategies normally utilized by adipocytes. This process is driven by constitutively activated STAT3 and is inhibited by ibrutinib.

INHIBITION OF ARGININE UPTAKE VIA HUMAN CATIONIC AMINO ACID TRANSPORTER-1 (CAT-1): A NOVEL APPROACH FOR CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) THERAPY

A. Werner[1,2], N. Leuchtner[1,3], A. Habermeier[2], H. Echchannaoui[1,3], J. Rupp[2], K. Rajalingam[3,4], M. Theobald[1,3,4], E. Closs[2], M. Munder[1,3,4,*]
[1]Third Department of Medicine (Hematology, Oncology, and Pneumology), [2]Department of Pharmacology, University Medicine Mainz, Mainz, [3]German Cancer Consortium (DKTK), partner site Frankfurt / Mainz, German Cancer Research Center (DKFZ), Heidelberg, [4]Research Center for Immunotherapy, University Medicine Mainz, Mainz, Germany

Background: Interference with cancer metabolism by specifically restricting extracellular nutrients is a rapidly emerging field of research. A variety of tumor entities depend on the availability of the amino acid arginine since they have lost the ability to synthesize it endogenously. The systemic depletion of arginine, induced by the arginine-metabolizing enzymes arginine deiminase or arginase is currently explored clinically in phase I-II studies. An alternative, largely unexplored strategy to restrict nutrient availability for cancer cells would be to target the specialized cell membrane transporter proteins. Arginine uptake into cells is mediated by members of different solute carrier families (hCAT-1, hCAT-2A, hCAT-2B, hCAT-3; y^+LAT1, y^+LAT2, $ATB^{0,+}$and $b^{0,+}$AT), which differ in expression and regulation between individual cell and tissue types.
Aims: We wanted to clarify (i) if CLL cells depend on exogenous arginine, (ii) which transporter is responsible for arginine transport in human CLL cells and (iii) if the reduction of arginine availability via knockdown of this transporter inhibits CLL cell growth and viability.
Methods: Experiments were performed with both, primary human CLL cells, isolated from highly leukemic peripheral blood, and immortalized CLL cell lines. Primary CLL cells were left unstimulated or were stimulated via Toll-like receptor 9. The expression levels of arginine transporters were determined by quantitative RT-PCR and Western Blot. Arginine uptake was measured by [^{3}H]-arginine import, cell proliferation by [^{3}H]-thymidine DNA incorporation and cell viability by Annexin-V + propidium iodide staining in flow cytometry. The expression of hCAT-1 was downregulated in HG3 CLL cells using lentiviral shRNA technology. HG3_hCAT-1_knockdown cells were injected s.c. in NOD/SCID/gc^{null} mice and tumor growth was monitored.
Results: We show that primary CLL and immortalized CLL cell proliferation depends on the availability of extracellular arginine. Screening a large panel of individual CLL patient samples and different immortalized CLL cell lines demonstrated that hCAT-1, y^+LAT1 and y^+LAT2 are the predominantly expressed arginine transporters. Upon activation the expression level of hCAT-1 further increased significantly. Arginine uptake both, in primary CLL cells and in the CLL cell lines, was inhibited by the CAT inhibitor N-ethylmaleimide. Lentiviral downregulation of the hCAT-1 transporter in HG3 CLL cells resulted in a significant reduction of arginine uptake, associated with an inhibition of cell proliferation and viability *in vitro*. The corresponding *in vivo* data of tumor growth upon hCAT-1 knockdown in a murine xenograft model will be presented at the conference.
Summary/Conclusions: Our results demonstrate that the hCAT-1 transporter is a potential pharmacological target structure in CLL cells. Development of small molecule- or antibody-based inhibitors of hCAT-1 might lead to a novel therapeutic approach for CLL.

E993

FCMR IS A NEGATIVE REGULATOR OF B-CELL RECEPTOR SIGNALING IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

S. Gobessi[1,*], B. Sasi[1], G. Pozzato[2], I. Innocenti[3], L. Laurenti[3], D. Efremov[1]
[1]Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, [2]Department of Medical and Surgical Sciences, University of Trieste, Trieste, [3]Institute of Hematology, Catholic University Hospital "A. Gemelli", Rome, Italy

Background: Chronic lymphocytic leukemia (CLL) cells frequently display features of anergic B cells, including reduced B-cell receptor (BCR) signaling capacity and downregulation of membrane IgM (mIgM). These features are particularly evident in freshly isolated peripheral blood (PB) CLL cells belonging to the indolent, M-CLL subset (Lanham S et al, Blood. 2003). The mechanism responsible for this phenomenon is still unclear, but chronic stimulation with autoantigens has been considered as a possible explanation because of the observation that BCR signalling capacity and mIgM expression can spontaneously recover in CLL cells following prolonged *in vitro* culture (Mockridge CI et al, Blood. 2007). An alternative explanation for this phenomenon is that these anergic features are induced by soluble IgM molecules, which are absent from standard cell culture media, and could interact *in vivo* with the leukemic BCRs through recently described intermolecular immunoglobulin interactions or by binding to the Fcμ receptor (FcμR). The latter is highly overexpressed in CLL cells, particularly those belonging to the M-CLL subset (Li FJ et al, Blood. 2011).
Aims: Investigate the role of the FcμR in regulating BCR signaling in CLL cells.
Methods: CLL cells were isolated from PB or lymph nodes (LNs) using standard procedures. FcμR stimulation was done using pentameric human Fcμ fragment, whereas BCR stimulation was done using goat anti-human IgM or anti-human Ig light chain F(ab')2 fragments. FcμR knockdown was done by RNA interference using the Nucleofector system and solution V/C-009 program. Surface FcμR and IgM levels were measured by flow cytometry on gated CD19+/CD5+ cells.
Results: We recently reported that FcμR stimulation results in activation of certain downstream BCR signaling pathways and increased CLL cell survival *in vitro* (Gobessi S et al, ASH 2016, abstract 2015). To investigate whether FcμR regulates BCR signaling capacity, we analyzed activation of downstream signaling molecules in CLL cells that had been pretreated for one hour with Fcμ and then stimulated with an anti-Ig light chain antibody. Decreased phosphorylation of SYK, AKT and ERK was detected in the Fcμ-treated samples, suggesting that FcμR negatively regulates BCR signaling in CLL cells. Consistent with this finding, we also observed that FcμR knockdown by RNA interference resulted in greater activation of SYK, AKT and ERK in anti-IgM stimulated primary CLL cells. Because IL-4 was recently shown to increase BCR signaling capacity and surface IgM expression on CLL cells (Aguilar-Hernandez MM et al, Blood. 2016; Guo B et al, Blood 2016), we next investigated whether it will have an opposite effect on FcμR expression. Stimulation of CLL cells (n=7) for 48 hours with IL-4 resulted in a mean 2.4 fold reduction in surface FcμR expression and a 3.9 fold increase in surface IgM expression compared to unstimulated cells ($P<0.001$ and $P=0.016$, respectively). Since IL-4 is produced by T cells, which typically interact with CLL cells in LNs, we next compared surface FcμR and IgM expression in two paired LN and PB CLL samples. Interestingly, in both cases the levels of surface FcμR were lower on LN than PB CLL cells, whereas no difference was detected in the expression of surface IgM. To further understand the mechanisms through which IL-4 regulates BCR signaling, we compared BCR signaling capacity of CLL cells cultured for 48 hours in the pres-

ence or absence of IL-4. Most of the investigated samples in this series showed reduced surface FcμR expression and increased surface IgM expression after IL-4 treatment, but a few cases showed only reduced FcμR expression and no change in IgM expression. Interestingly, these samples also showed greater anti-IgM induced phosphorylation of SYK, PLCγ2, AKT and ERK, suggesting that downregulation of FcμR is the primary mechanism through which IL-4 regulates the BCR signaling capacity of CLL cells.
Summary/Conclusions: These data show that FcμR is a negative regulator of BCR signaling in CLL cells. Overexpression of FcμR could be at least in part responsible for the reduced BCR signaling capacity of PB CLL cells. FcμR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

Background: Aging is characterized by a progressive decline in immune surveillance that favors tumor development in older patients. One mechanism used by malignant cells to escape immune surveillance is the upregulation of immune checkpoint inhibitors. Another process associated with aging is genetic or epigenetic modifications of tumor suppressor genes (TSGs).
Aims: We previously reported a correlation between 6q deletion and progression into a T cell lymphoproliferative disease, identifying the *BACH2* gene as a candidate TSG. We thus examined the expression of specific transcription factors (*BACH2 and PRDM1)* and checkpoint inhibitors (*PD-1* and *PD-L1*) in the major lymphocytes subsets for their potential role in immunosenescence.
Methods: Peripheral blood mononuclear cells were isolated from whole blood using Lymphoprep (Stemcell Technologies) density gradient centrifugation. Lymphocyte subsets (CD19+, CD3+CD4+; CD3+CD8+) were isolated for subsequent molecular analyses using the MACS Technology (Miltenyi), with the purity of each lymphocyte subpopulation between 95%>99%. PD-1 (*PDCD1*), PD-L1 (*CD274*), *IL4*, *IFNG*, *BACH2* and *PRDM1* mRNA transcripts were quantified using qRT-PCR. *BACH2* and *BLIMP1 (PRDM1)* protein expression were examined by Western blotting.
Results: Blood samples were obtained from 60 healthy volunteers and 41 untreated B-cell chronic lymphocytic leukemia (B-CLL) patients (median: 67yo). Healthy donors (HD) between the ages of 20 to 90 years subdivided into <50 yrs (median: 36yo) and ³50 yrs (median: 65yo). *BACH2* mRNA expression in the HD groups is significantly down-regulated in CD4+, CD8+ T cells and CD19+ B cells from the older HD group (p=0.0012; 0.0045 and 0.0367, respectively). *BACH2* expression was further reduced in CD4+, CD8+ T cells and CD19+ B cells from CLL patients compared to HD well balanced for age (p=0.001; <0.0001 and 0.0043). *PRDM1* mRNA expression was inversely correlated with *BACH2* in $CD4^+$, $CD8^+$ T cells and $CD19^+$ B cells (r=0.61; 0.71 and 0.65, respectively). Curiously, *PRDM1* was – as expected - significantly up-regulated in CD4+ and CD8+ T cells (p=0.0034; p=0.0017) from B-CLL patients but not in their leukemic B cells. Western blotting analysis demonstrated that *BACH2* and *BLIMP1* (*PRDM1*) protein expressions in the T and B cell subpopulations were significantly correlated with transcript expression. *BACH2*-deficient mice have been shown to have an increased numbers of *IL4*-producing $CD4^+$ T cells. We also observed that *BACH2* down-regulation is correlated with increased *IL-4* mRNA expression (r=0.67) but not *IFNγ* in $CD4^+$ T cells. These observations suggest that *BACH2* down-regulation in $CD4^+$ T cells could enhance the expression of effector memory-related genes, particularly Th2, such as *IL-4* and *PRDM1*. *PD-1* mRNA expression was up-regulated in $CD4^+$, $CD8^+$ T cells (p=0.0153 and 0.0214) in the older HD group and also up-regulated in the T cells from B-CLL patients (p=0.0014 and 0.0023) when compared to age-matched HD population. High *PD-L1* mRNA expression was correlated with increased age in HD B cells (p=0.04) with a further increase detected in leukemic B cells (p=0.001). We also observed an inverse correlation between *BACH2* and *PD-1* in $CD4^+$, $CD8^+$ T cells (r=0.62 and 0.68); and between *BACH2* and *PD-L1* in $CD19^+$ B cells (r=0.66).
Summary/Conclusions: These data suggest that down-regulation of *BACH2/PRDM1* and up-regulation of *PD1/PD-L1* mRNA expression in major lymphocyte subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the immunosenescence process.

T-CELL EXHAUSTED PHENOTYPE IS ENHANCED DURING DISEASE PROGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)
I. Jiménez[1,*], S. Bobillo[2], P. Abrisqueta[2], C. Palacio[2], J. Carabia[1], M.J. Terol[3], M. Crespo[1], F. Bosch[1]
[1]Experimental Hematology, [2]Hematology, Vall d'Hebron Institute of Oncology, Barcelona, [3]Hematology, INCLIVA Biomedical Research Institute, Valencia, Spain

Background: The different biological mechanisms leading the clinical progression of CLL from early stages are currently not fully elucidated. Different prognosis factors that correlate with a higher probability of progression, such as IgHV mutational status, ZAP70 or CD49d expression, or TP53 defects, are still not able to identify an important proportion of patients that eventually progress. Clinical progression from early stages to an advanced CLL is associated with a certainly reduced acquisition of molecular changes that are not able to explain the fifty percent of the CLL cases progressing. CLL cells are dependent on survival and proliferative signals from the microenvironment and are able to evade immune anti-tumoral responses using different mechanisms, which is a crucial feature for cancer development. T-cell dysfunction is one of the main sources of impaired anti-tumor immunity. In CLL, T cells show functional defects and have increased expression of the exhaustion markers PD1, CD244 and CD160 compared to T cells from healthy individuals. Taking this into account, we hypothesize that changes in the microenvironment, and particularly in T-cell exhaustion component, are contributing to the clinical progression of CLL.
Aims: In order to explore the role of the immune system in the progression of CLL we studied the immunophenotype of T cells from CLL patients using paired samples at diagnosis and progression.
Methods: A total of 14 CLL patients (median age, 69 years; median time to progression of 29,5 months) and 6 patients diagnosed with CLL that did not experience clinical progression during a median follow up of 34 months were included in the study. Multicolor flow cytometry was performed in matched samples at two time-points: diagnosis and progression before treatment or diagnosis and follow-up. We studied T-cell differentiation status based on CD45RA and CCR7 expression and the inhibitory receptors PD1, CD244, CD160, LAG3, TIM3 and CTLA4. We also analyzed the expression of the transcription factors T-bet and Eomes.
Results: We observed a significant increase in $CD8^+$ absolute numbers (P=0.0107) and a significant decrease of the CD4:CD8 ratio (P=0.0012) with progression. T cells increased their effector memory (EM) $CD45RA^-$ $CCR7^-$ phenotype during progression (EM $CD4^+$ P=0.0353; EM $CD8^+$ P=0.0023). PD1 expression was significantly increased during progression in absolute numbers on both $CD4^+$ and $CD8^+$ T cell subsets (P=0.0166), as well as in the $PD1^+$ EM subset (EM $PD1^+CD4^+$; EM $PD1^+CD8^+$ P=0.0024). Interestingly, we did not observe these changes in CLL patients that did not progress where the absolute numbers of cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We observed that the percentages of $CD8^+$ cells expressing CD244 and CD160 were higher at the time of progression, especially for CD244 (P=0.0078). Moreover, the co-expression of these markers with PD1 was found on $CD8^+$ T cells and its percentage was increased during progression (P=0.0078). Among the differentiation subsets, the EM and EM $CD45RA^+$ (TEMRA) $CD8^+$ T cells expressed the highest percentages of CD244 and CD160. We did not observe changes in LAG3, TIM3 and CTLA4. T-bet and Eomes are essential to regulate T-cell differentiation and their expression has also been associated with a progenitor ($T\text{-bet}^{hi}$ $PD1^{int}$) or a terminal ($Eomes^{hi}$ $PD1^{hi}$) exhausted phenotype in chronic viral infections. The percentage of $CD8^+$ T cells expressing Eomes and co-expressing Eomes and PD1 were significantly increased during progression (P=0.0186 and P=0.0286, respectively) whereas T-bet expression was more stable.
Summary/Conclusions: T cells from patients with progressed CLL show a more severe exhausted phenotype compared to diagnosis, which is characterized by an effector memory subset with higher expression and co-expression of PD1, CD244 and CD160, as well as higher levels of the transcription factor Eomes, indicating that the terminal exhausted phenotype ($Eomes^{hi}$ $PD1^{hi}$) is predominant. These changes may contribute to the immune evasion that facilitates the progression and to the immunosuppresive scenario that dominates advanced CLL stages. Functional assays to explain why this T cell subset is enhanced during progression are currently ongoing.

E996

EARLY SPECIFIC INCREASED EXPRESSION OF SURFACE IGM BUT NOT OF OTHER ASSOCIATED MOLECULES APPEARS TO REFLECT ANTIGEN DISENGAGEMENT IN CLL PATIENTS ON IBRUTINIB THERAPY
S. Drennan[1,*], G. Chiodin[1,2], A. D'Avola[1], P.W. Johnson[3], L. Trentin[2], G. Packham[3], A.J. Steele[3], F.K. Stevenson[3], F. Forconi[1,4]
[1]Haematology Oncology Group, Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, [2]Padua University School of Medicine, Department of Medicine, Hematology and Clinical Immunology Branch, University of Padua, Padua, Italy, [3]Cancer Sciences Unit, University of Southampton, [4]Haematology Department, University Hospital Southampton NHS Trust, Southampton, United Kingdom

Background: B cell receptor (BCR) signaling through surface IgM (sIgM) is key to the survival and proliferation of normal and chronic lymphocytic leukemia (CLL) cells, and can be targeted effectively by the BTK inhibitor ibrutinib. Chronic exposure of the BCR to (super)antigen leads to downmodulation of sIgM,

but not of sIgD, levels and signaling capacity. This is evident in the circulating CLL B-cells which are characterized by variably reduced sIgM levels/signaling. The variability influences outcome and cases with relatively higher sIgM levels/signaling capacity, but not sIgD, have more rapid progression, likely due to a larger proliferative component.
Aims: The aim of this study was to investigate the effect of ibrutinib *in vivo* on the dynamics of expression and function of sIgM and of other surface molecules associated with the BCR complex on the circulating CLL cells of patients during the early phases of therapy (first 3 months).
Methods: Peripheral blood mononuclear cells were collected from 12 CLL patients prior to (pre-) and at 1 week, 1 month and 3 months following commencement of single agent ibrutinib therapy. Expression of BCR-complex associated sIgM, sIgD, CD19 and other surface markers was assessed by flow cytometry. Signaling capacity following sIgM stimulation was measured by immunoblotting. Following biotinylation of cell surface proteins, the N-glycosylation pattern of the μ chain was assessed by immunoblotting as a readout of sIgM status. Informed consent was obtained from all patients (REC: H228/02/t).
Results: At week 1 of ibrutinib therapy, there was a dramatic increase in the expression of sIgM on the circulating CLL cells (mean fold increase 1.6, *P*=0.001), while expression of sIgD and CD19 remained constant. At this time point, increased sIgM expression associated with full N-glycan maturation of sIgM heavy-chain, indicative of recovery from antigen engagement at tissue sites. Also, the sIgM levels correlated with increased anti-IgM mediated SYK phosphorylation (r=0.64, *P*=0.03), to indicate functionality upstream of BTK. Sequential assessment at month 1 and 3 revealed that sIgM levels were similar to that observed prior to therapy, with preserved upstream signaling ability. In marked contrast, the other BCR complex associated molecules sIgD, CD19 and CD20 all reduced expression (*P*<0.001). Reduction of these markers was also accompanied by reduction of cell size and of other surface markers while overexpression of autophagy marker LC3B2 was documented.
Summary/Conclusions: Our data point to two major events dissociating sIgM expression and function from other BCR-complex associated molecules. In the initial phase, the increased sIgM expression and maturation, with no changes of other BCR-associated molecules, appears consequent to lack of antigen encounter, likely due to inhibition of chemokine-mediated entry to tissue sites. In the later phases the circulating CLL cells will suffer lack of tissue derived pro-survival stimuli. In their absence, CLL cells will reduce expression of several markers and cell size, possibly explained by autophagocytic mechanisms aiming to protect the circulating CLL cells from death unless ibrutinib therapy is withheld.

TRB REPERTOIRE PROFILING OF TCL-1 TRANSGENIC MICE USING NOVEL NGS TECHNOLOGIES REVEALS OLIGOCLONAL EXPANSIONS: SIMILARITIES WITH CHRONIC LYMPHOCYTIC LEUKEMIA
A. Agathangelidis[1,2], A. Rovida[2], S. Bonfiglio[2], E. Vlachonikola[1], L. Scarfò[2,*], A. Hadzidimitriou[1], K. Stamatopoulos[1], P. Ghia[2]
[1]Institute of Applied Biosciences (INAB), Centre for Research and Technology Hellas (CERTH), Thessaloniki, Greece, [2]Strategic Research Program on CLL and B-cell neoplasia Unit, Division of Experimental Oncology, Università Vita-Salute San Raffaele and IRCCS Istituto Scientifico San Raffaele, Milan, Italy

Background: Findings from independent studies reported that the BcR pathway and antigenic stimulation occupy a central spot in the development of leukemia in the Eμ-TCL-1 transgenic (tg) mouse, as in the case of chronic lymphocytic leukemia (CLL). Recently, the detailed characterization of the T-cell receptor beta chain (TRB) gene repertoire in patients with CLL revealed gene expression biases and oligoclonality. These characteristics strongly suggested that not only leukemic B cells, but also T cells are selected by antigenic elements. In this context, very little is known regarding the T cell compartment in Eμ-TCL-1 mice.
Aims: Here, we sought to: (i) obtain a comprehensive view of the TRB gene repertoire in TCL-1 mice, and (ii) assess from an immunogenetic standpoint the extent of similarity between TCL-1 mice and CLL patients.
Methods: In total, we analyzed 18 samples from 16 TCL-1 mice that were categorized into 3 distinct groups, based on disease stage: (i) 6 mice with a clone size of <20% (group 1), (ii) 6 mice with a clone size of 30-55% (group 2) and (iii) 6 mice with a clone size of >60% (group 3). Clone size was measured as the percentage of CD5+/CD19+ B cells in the blood. Two different mice were studied longitudinally: one belonged originally to group 1 and progressed to group 2, while the other animal progressed from group 2 to 3. Five C57BL/6 wild-type (wt) mice were also analyzed as controls. TRBV-D-J gene rearrangements were amplified using the immunoSEQ® mouse T-cell receptor beta (mmTCRB) Kit from Adaptive Biotechnologies® and sequencing was performed using the MiSeq® Reagent Kit v3. Data were analyzed using the immunoSEQ® software.
Results: Only productive, in-frame TRBV-D-J rearrangements were included in the analysis that, in total, concerned 383,951 sequences (median 14,239 sequences). The TRB gene repertoire was almost identical in all groups, including the wt mice. In detail, 5 different genes: TRBV13-02, TRBV19-01, TRBV03-01, TRBV13-03, TRBV05-01, TRBV02-01 accounted for almost 50% of the total repertoire. Concerning the TRBJ gene repertoire, the TRBJ02-07 gene was the most frequent gene in all groups. The analysis of the CDR3 length showed the same distribution in all groups with the mean and median CDR3 length being 12 amino acids. Expanded clones were observed in all samples with the average size of the 10 largest clones being: 9.8% for group 1, 18.3% for group 2, 12.9% for group 3 but only 0.4% for wt mice. Comparison of the TRBV repertoire in the expanded clones *versus* the general cohort revealed significant differences with genes TRBV12-01, TRBV12-02, TRBV16-01 and TRBV20-01 being frequent only in the former group. Shared or public clonotypes (identical CDR3 sequences) were only observed in longitudinal samples from the same mice, which also concerned some of the largest clones. Scanning the 10 largest clones of each sample for the existence of highly similar clones led to the identification of 48 clusters that contained 91/180 clonal sequences.
Summary/Conclusions: Overall, the TRB gene repertoires of TCL1 mice were characterized by oligoclonal expansions that could persist over time. The TRB gene repertoire of expanded clones was more restricted than that of the general cohort, whereas comparisons between different samples revealed the existence of identical and highly similar clonotypes. These findings argue that (ongoing) selection by antigenic elements may shape the T-cell compartment in TCL-1 mice, similar to human CLL. These results further support the notion that this mouse model closely resembles CLL, at least from an immunogenetic perspective.

E998

ROLE OF THE COMBINATION MEK1/2 INHIBITOR BINIMETINIB AND AKT INHIBITOR MK2206 IN CLL
S. Sandhu[1,2,*], S. Mulligan[2,3], G. Best[2]
[1]Acute Medical Unit, Royal Melbourne Hospital, Parkville, [2]Northern Blood Research Centre, Kolling Institute of Medical Research, [3]Haematology, Royal North Shore Hospital, St Leonards, Australia

Background: Clinical trials of ibrutinib and idelalisib demonstrate the efficacy of B-cell receptor-targeted therapies for CLL. We sought to investigate the efficacy of targeting both the BCR and the MAPK-ERK1/2 signaling pathways.
Aims: To evaluate the role of targeting the Ras-Raf-MEK1/2-ERK1/2 together with the Pi3K-AKT pathways as a potential novel approach in treating chronic lymphocytic leukemia. In particular, assessing the efficacy of MEK1/2 inhibitor, binimetinib (MEK162), in combination with either a Pi3K inhibitor, idelalisib or an AKT inhibitor, M2206.
Methods: All experiments conducted on primary CLL cells were co-cultured with CD40L-expressing stroma which mimics the support conferred by the tumour environment. Firstly, the effects of MK2206 and idelalisib at doses varying from 1 to 40μM were tested on primary CLL cells. Secondly, binimetinib and MK2206 were tested as single agents and in combination at 20μM against primary CLL cells. Thirdly, binimetinib at 20μM combined with varying doses of idelalisib on primary CLL cells. The mechanisms underlying the effects of binimetinib in combination with MK2206 in primary CLL cells were investigated by western blotting with changes in the expression of phosphorylated and total forms of AKT, MCL-1, and ERK1/2 assessed. Expression of B-actin was used as a loading control.

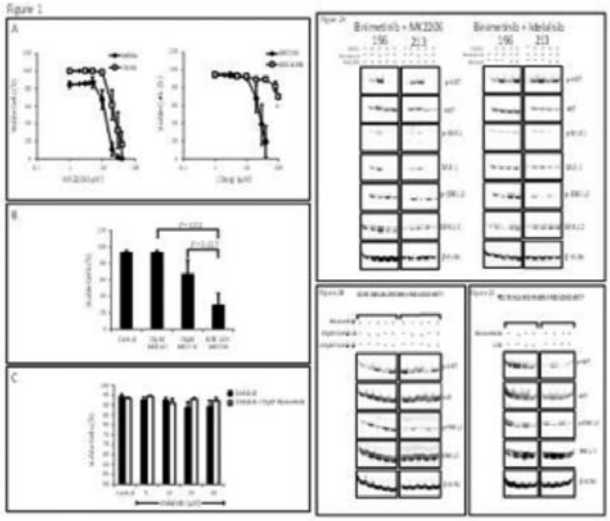

Figure 1.

Results: MK2206 is effective against CLL cells co-cultured with stromal cells in a dose dependent manner. It was also observed that the primary CLL cells co-cultured with the CD40L-expressing stroma were significantly more sensitive to MK2206 than to idelalisib (Figure 1A). No cytotoxic effects of binimetinib

were observed while the combination with MK2206 was significantly more effective than either drug alone, suggestive of synergy between the two drugs (Figure 1B). The analysis of binimetinib at 20μM with idelalisib failed to demonstrate any additive effects or suggestion of synergy between the two drugs (Figure 1C). Binimetinib treatment led to an increase in the activity of AKT and a decrease in ERK1/2 phosphorylation. MK2206 completely abrogated the activity of AKT and MCL-1 phosphorylation when combined with binimetinib (Figure 2A). Although we observed a reduction in AKT phosphorylation following idelalisib alone, it had no effect on the levels of AKT activity induced by binimetinib or the levels of phosphorylated MCL-1 protein. This result was irrespective of the dose of idelalisib used (Figure 2B). We explored the possibility that protein kinase C (PKC) may also be involved in the binimetinib-induced AKT activity. Using the pan-PKC inhibitor GF109203X (GFX), we demonstrated that inhibition of PKC significantly reduces binimetinib-induced phosphorylation of AKT with no effect on the activity of ERK1/2-MAPK (Figure 2C). These data suggest a role for PKC in the regulation of AKT activity in CLL cells.

Summary/Conclusions: The combination of binimetinib and MK2206 *in vitro* has been shown to be effective strategy to treat primary CLL cells. The western blot data reinforce that the increased activity observed in AKT activity in CLL cells following binimetinib treatment is independent of the idelalisib and totally abrogated by MK2206. This PI3-kinase independent regulation may be regulated by protein kinase C and is likely to play a significant role.

Dual inhibition of MAPK-ERK1/2 and AKT signaling may be effective at targeting the proliferative/drug-resistant compartment of CLL that resides in the tumour microenvironment.

TARGETING HIF-1A AND ITS REGULATORY PATHWAYS AS A STRATEGY TO HAMPER LEUKEMIA-MICROENVIRONMENT INTERACTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA

C. Vitale[1,2,*], V. Griggio[1,2], M. Todaro[1,2], C. Riganti[3], I. C. Salaroglio[3], C. Salvetti[1,2], M. Rigoni[1,2], M. Foglietta[2,] B. Castella[2], M. Boccadoro[1,2], M. Massaia[2,4], M. Coscia[1,2]

Background: The CXCL12/CXCR4 axis has a fundamental role in the microenvironment-mediated protection of chronic lymphocytic leukemia (CLL) cells from spontaneous and drug-induced cell death. The binding of CXCL12 with CXCR4 activates multiple intracellular pathways, including RhoA- and Ras-dependent signaling. We have previously shown that co-culture with stromal cells (SC) induces in CLL cells the activation of RhoA/RhoA kinase and Ras/ERK1-2 signaling, the upregulation of Akt, and an increased activity of the transcription factor HIF-1α (Rigoni et al., Oncotarget 2015).

Aims: The purpose of this study was to identify new potential pharmacological targets involved in the CXCL12/CXCR4 axis in order to impair the protection exerted by SC towards spontaneous and fludarabine-induced apoptosis in CLL cells.

Methods: Peripheral blood was collected from 62 patients with CLL. In selected experiments, the M2-10B4 murine SC line and the HS-5 human SC line were used. Patient-derived bone marrow SC were generated from 12 patients with CLL. Where indicated, cell cultures were treated with recombinant CXCL12 (100 ng/ml), CXCR4 inhibitor AMD3100 (5 μg/ml), fludarabine (F-ara-A, 10 μM), simvastatin (1 μM), ERK1-2 kinase inhibitor PD98059 (10 μM), HIF-1α inhibitor BAY87-2243 (1 μM), and PI3K inhibitor idelalisib (10 μM). RhoA and Ras activities were evaluated by an ELISA based assay and by pull-down assay, respectively. ERK1-2, HIF-1α amount in whole cell extracts and in nuclear fraction, and HIF-1α phosphorylation were evaluated by Western Blot. RhoA kinase, Akt and HIF-1α activities were measured with specific immunoassay kits. CXCL12 was quantified by ELISA. Cell viability was determined by Annexin-V/propidium Iodide immunostaining and flow cytometry analysis.

Results: The exposure of CLL cells to recombinant CXCL12 led to the activation of RhoA- and Ras-dependent signaling, and to the downstream upregulation of HIF-1α. The CXCR4 antagonist AMD3100 completely abrogated the positive regulation exerted by both CXCL12 and SC, thus unveiling the key role of the CXCL12/CXCR4 axis in the SC-induced modulation of these signaling pathways. The inhibition of Ras and RhoA activity by simvastatin, and the inhibition of ERK1-2 and HIF-1α by PD98059 and BAY87-2243 effectively blocked the SC-induced expression and activity of HIF-1α, significantly impairing the SC-mediated protection of CLL cells, both in absence and presence of fludarabine. Similar effects were observed by targeting the PI3K/Akt pathway with idelalisib. We then investigated whether targeting RhoA- and Ras-dependent signaling could modulate HIF-1α also at the SC level. Simvastatin and BAY87-2243 effectively inhibited HIF-1α expression both in SC lines and in patient-derived SC. Moreover, simvastatin significantly reduced the secretion of CXCL12, which is a known transcriptional target of HIF-1α.

Summary/Conclusions: Our data demonstrate that the targeting of HIF-1α and its regulatory pathways, both at the tumor cell and at the SC level is an appealing strategy to overcome the microenvironment-mediated protection toward spontaneous and fludarabine-induced apoptosis in CLL cells.

Anna Hospital, Ferrara, [5]Department Medical Sciences, University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Chemoimmunotherapy with fludarabine, cyclophosphamide and rituximab (FCR) is the optimal front-line treatment for fit chronic lymphocytic leukemia (CLL) patients. IGHV mutations and FISH lesions are predictive markers of response and progression-free survival after FCR. Minimal residual disease (MRD) is the single best post-treatment predictor of long-term outcome after FCR, independent of biologic prognostic markers.

Aims: To explore whether conventional biologic markers (*i.e.* IGHV mutations, FISH lesions) and *TP53*, *NOTCH1*, *BIRC3* and *SF3B1* mutations can predict the obtainment of a MRD negativity after first-line treatment of CLL patients with FC and ofatumumab (FCO).

Methods: Eighty young (≤65 yrs) and fit CLL patients from 15 Italian centers were enrolled in the GIMEMA LLC0911 first-line trial and treated with 6 cycles of FCO. CLL diagnosis, treatment requirement and response were defined according to the 2008 iwCLL guidelines. MRD was evaluated in responding patients by 8-color flow cytometry in the peripheral blood (PB) and bone marrow (BM) 2 months after the end of induction (month +8), and every 6 months thereafter; flow negative cases were analyzed by RQ-PCR, according to the guidelines. The association between CLL biologic markers and MRD clearance after FCO was tested by Fisher's exact test; logistic regression models were used to estimate the risk values in univariate and multivariate analyses.

Table 1.

Table 1: Biologic features of the 65 CLL patients evaluated for MRD.

Median age	59 years (36-66)
Morphology (tipycal/atypical)	31/7
IGHV (unmutated/mutated)	37/27
CD38 (pos/neg; cut-off 20%)	35/30 (54%)
CD49d (pos/neg; cut-off 30%)	37/23 (62%)
ZAP70 (pos/neg; cut-off 20%)	9/50 (15%)
FISH: del17p	2/64 (3%)
del11q	11/64 (17%)
trisomy 12	5/64 (8%)
del13q	21/64 (33%)
No FISH lesions	25/64 (39%)
TP53 mutation (one *TP53*mut+del17p+)	2/65 (3%)
NOTCH1 mutation	9/65 (14%)
BIRC3 mutation	3/65 (5%)
SF3B1 mutation	9/65 (14%)

Results: Sixty-five responding patients underwent MRD evaluation at month +8; their biologic features are reported in the Table. By flow cytometry, 25/65 cases (38%) resulted MRD+ in the PB and/or BM, while the remaining 40 (62%) showed no residual CLL cells. The absence of del17p/*TP53*mut/del11q was associated with the achievement of MRD negativity: 37 MRD- (74%)/13 MRD+ among patients with trisomy 12/negative FISH/del13q/*TP53*WT *vs* 2 MRD- (14%)/12 MRD+ among del17p+/*TP53*mut/del11q+ (p=0.0001). Interestingly, when patients were stratified into high (n=6), intermediate (n=22), low (n=21) and very-low risk (n=15) groups by integrating FISH and gene mutations (Rossi

et al, 2013), the high and intermediate risk groups (del17p/*TP53*/*BIRC3*+ or del11q/*NOTCH1*/*SF3B1*+) showed a significantly lower probability of achieving a MRD negativity (36%, 10/28) than the low and very-low risk groups (+12/negative FISH/del13q/WT for 4 genes: 81%, 29/36) (p=0.0003). The 40 flow cytometry MRD- cases were also evaluated by RQ-PCR: 22 (55%) were reclassified as MRD+. By combining the two methods, 47/65 cases (72%) were MRD+ and 18/65 (28%) MDR- at the end of FCO. Mutated (M)-IGHV status was significantly associated to a molecular MRD- (12 MRD-/15 MRD+, 44%) compared to unmutated (UM)-IGHV cases (5 MRD-/32 MRD+, 13%) (p=0.0092). Moreover, when M-IGHV status is reinforced by the absence of del17p/*TP53*mut/del11q, the association with a deep MRD negativity got stronger (12 MRD-/13 MRD+, 48% *vs* 5 MRD-/33 MRD+, 13%; p=0.0036). A multivariate model including FISH lesions, gene and IGHV mutations supports the independent role of FISH and IGHV profile in predicting MRD negativity by flow and RQ-PCR, respectively.

Summary/Conclusions: In CLL patients treated with the FCO combination (LLC0911 Gimema trial), MRD negativity by flow cytometry (62%) can be predicted by the FISH profile: 74% in patients without del17p/del11q *vs* 14% in del17p+/del11q+ cases. A deeper MRD negativity by RQ-PCR (28%) can be anticipated by the IGHV status (44% M *vs* 13% UM) or by combining IGHV and FISH. A longer follow-up will determine whether these parameters can identify patients who maintain over time a good quality of response.

Background: Chromosomal abnormalities are present in about 80% of CLL. Among them, the loss of the short arm of the chromosome 17 (17p-), uncommon at diagnosis (<10%), is frequent in relapsed or refractory patients (up to 50%) and is associated with short survival. Loss of 17p results from various chromosomal abnormalities, including unbalanced translocations, deletions, rings or isochromosomes. All these aberrations lead to the loss of one copy of the *TP53* gene, the remaining allele being generally mutated. In addition, 17p- is frequently accompanied by genomic complexity. Patients with 17p- typically progress quickly and are refractory to most conventional therapies.

Aims: We evaluated if the type of chromosomal abnormality leading to 17p- and the additional aberrations could influence the prognosis.

Methods: We collected data from a multicentric and retrospective cohort of 195 CLL patients harboring a *TP53* deletion detected by FISH, with an informative conventional karyotype (K). All the K were reviewed by the members of the Groupe Francophone de Cytogénétique Hématologique. Overall survival (OS) and time to first treatment (TTFT) were calculated from diagnosis to death or first-line treatment, respectively, or last follow-up. The log-rank test was used to compare Kaplan-Meier curves. Cox regression models were used for multivariate analyses.

Results: The ratio H/F was 1.9. At diagnosis of CLL, the median age was 63 years [33-88], 59% were Binet stage A, 28% B, 12% C. *IGHV* genes were unmutated in 38/47 (81%) patients tested. The median follow-up was 70 months [0-401]. The majority of the patients was treated (87%), with a median TTFT of 13 months and a median of 2 lines of treatment [1-10]. In 28/124(23%) cases, the 17p- was not present at diagnosis and occurred after the first therapy, with a median time of 77.5 months [22-291] from the diagnosis. Karyotype was complex in 141/195(72%) patients, and monosomal in 90/195 (46%). The 17p- was the sole abnormality detected by K in 28/195(14%) cases. A total of 240 17p abnormalities were found in the 195 patients. In the majority of cases, loss of 17p was the consequence of an unbalanced translocation (n=167/240, 70%), with various chromosome partners, the most frequent being the recurrent der/dic(17;18)(q10;q10) (n=32, 13%), followed by translocations involving chromosomes 8, 13, 14, 21, 15. Unbalanced translocations involving 17p and chromosome 8 (n=26, 11%), lead either to del8p (n=17), gain8q (n=6), or del8q (n=3). The other 17p abnormalities were: deletion 17p (n=45, 19%), monosomy 17 (n=15, 6%), isochromosome 17q [i(17q)] (n=9, 4%) and ring of chromosome 17 (n=4, 1%). Among the additional abnormalities accompanying the 17p-, unbalanced translocations were found in 121/195(63%) of patients. Combining FISH and K, del13q was detected in 71/118(60%) of cases, del8p in 40/189(21%), tri12 in 30/195(15%), gain8q in 13/105(12%), and del11q in 20/161(12%). By univariate analysis, the paramaters which were associated with significantly shorter OS were: age ≥65 years, stage B/C, unmutated *IGHV*, i(17q) (69 months *vs* 179, p=.0375), the presence of unbalanced translocations in addition to 17p- (153 *vs* 223 months, p=.03), and gain8q (74 *vs* 123 months, p=.0014). Monosomy 17, a total number of abnormalities ≥6 and gain8q predicted a shorter TTFT. By multivariate analysis, age ≥65 years, stage B/C and gain8q remained significant for OS.

Summary/Conclusions: Among the high risk group of 17p- CLL, i(17q) confers a shorter OS than the other 17p abnormalities. In addition, the gain8q aggravates the outcome as well as the presence of additional unbalanced translocations. These results confirm that patients with 17p- CLL have a variable clinical course and highlight the relevance of conventional karyotyping to identify the alterations that modulate the prognosis within these patients.

THE MICROENVIRONMENT REGULATES THE EXPRESSION OF MIR-21 AND TUMOR SUPPRESSOR GENES PTEN, PIAS3 AND PDCD4 THROUGH ZAP-70 IN CHRONIC LYMPHOCYTIC LEUKEMIA

J. Carabia[1,*], C. Carpio[2], P. Abrisqueta[2], I. Jiménez[1], N. Purroy[1], E. Calpe[1], C. Palacio[2], F. Bosch[1], M. Crespo[1]

[1]Experimental Hematology, [2]Hematology, Vall d'Hebron Institute of Oncology, Barcelona, Spain

Background: Microenvironment found in bone marrow and lymph nodes supports survival, proliferation and drug resistance in chronic lymphocytic leukemia (CLL). Indeed, CLL cells are highly dependent on interactions with the microenvironment. The BCR is one of the key players involved in the crosstalk between CLL cells and the microenvironment. Furthermore, it has a critical role in pathogenesis and prognosis of CLL. Accordingly, different factors related to increased BCR signaling are adverse prognostic factors in CLL, such as IGHV genes, high expression of ZAP-70 and increased serum levels of CCL3. Expression of ZAP-70 in CLL cells has been related to enhanced response to BCR stimulation, as well as to increased response to diverse migrative and survival stimuli from the microenvironment. MiR-21 is an oncogenic microRNA that has been found to be overexpressed in a wide variety of neoplasms where it participates in oncogenic events such as proliferation, resistance to treatment, and metastasis; its overexpression in CLL has been associated to refractoriness to fludarabine and to shorter overall survival and higher probability of progression.

Aims: In order to further elucidate the molecular mechanisms defining bad prognosis CLL by further elucidation of the role of ZAP-70 in the crosstalk between CLL cells and the microenvironment, we studied the relationship between ZAP-70 protein and miR-21 and how it is influenced by the microenvironment.

Methods: Peripheral blood mononuclear cells (PBMC) from 48 patients diagnosed with CLL were isolated by Ficoll-Paque Plus density gradient centrifugation. Ramos B-cells stably transfected with a vector encoding for ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control were treated with Akt (LY294002), MAPK (PD98059) and STAT3 (JSI-124) inhibitors for 1 hour. BCR was stimulated with $F(ab)_2$ anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimick the microenvironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels of primary miR-21, miR-21, PTEN, PDCD4 and PIAS3 were measured by QRT-PCR.

Results: First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected Ramos B-cells with ZAP-70 protein we found that pri-miR-21 and mature miR-21 expression were significantly increased upon BCR crosslinking, which was enhanced by ectopic expression of ZAP-70. We also observed that inhibition of both MAPK and STAT3 pathways impairs the regulation of miR-21 expression after ZAP-70 activation. Moreover, the induction of miR-21 expression after ZAP-70 activation also induced downregulation of the tumor suppressor genes PTEN, PDCD4 and PIAS3, targeted by miR-21 in malignant cells. The co-culture of primary CLL cells induced ZAP-70 and miR-21 expression, as well as downregulation of the putative miR-21 targets. Interestingly, the increase in miR-21 after co-culture was significantly impaired by ibrutinib, indicating that the BCR signaling pathway is involved in its regulation in primary CLL cells. Finally, co-culture-induced increased CLL survival correlated with miR-21 upregulation.

Summary/Conclusions: In conclusion, stimuli from the microenvironment are capable of regulating expression of miR-21 and tumor suppressor genes

(PTEN, PDCD4 and PIAS3) via a signaling pathway involving ZAP-70, MAPK and STAT3 transcription factor.

E1003

IMPACT OF RECURRENT MUTATIONS ON PROGRESSION-FREE SURVIVAL IN CLL PATIENTS TREATED WITH FRONT LINE RITUXIMAB-BASED REGIMENS

M. Hlozkova[1,*], J. Malcikova[1], N. Tom[1], M. Borsky[1], Y. Brychtova[1], M. Doubek[1], A. Panovska[1], E. Diviskova[1], M. Mraz[1], S. Pospisilova[1], J. Mayer[1], M. Trbusek[1]
[1]University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Brno, Czech Republic

Background: Regimens consisting of rituximab and DNA-damaging drugs represent an important therapeutic option for patients with chronic lymphocytic leukemia (CLL). Up-to-date studies including clinical trials agreed upon the adverse outcome of *TP53*-defective patients that should be provided alternative treatment approaches. Additionally, mutations in *NOTCH1* gene were connected with a lack of benefit from rituximab added to chemotherapy. A potential impact of other mutations commonly occurring in CLL patients remains less clear, namely regarding a role in relapse development.
Aims: (a) to assess impact of mutations in *ATM*, *SF3B1*, *NOTCH1* and *BIRC3* genes on progression-free survival (PFS) in CLL patients treated with front line rituximab-based regimens, and (b) to analyze clonal evolution of mutations in relapse.
Methods: We analyzed 53 CLL patients administered first line regimens FCR (fludarabine, cyclophosphamide, rituximab) or Q-FCR (FCR with reduced doses) or BR (bendamustine, rituximab); all harbored intact *TP53* gene as assessed by FISH and the yeast functional analysis; 46/53 (87%) had unmutated IGHV. The next generation sequencing using MiSeq (Illumina) was done in 53 pre-therapy samples and 41 relapsed samples using three separate panels: *ATM* (exons 2-63; median coverage (MC) 6100), *SF3B1*/*NOTCH1*/*BIRC3* (exons 14-16, part of 34, and 7-10, respectively, MC 11200), and *TP53* (exons 2-11; MC 31500). Functional impact of *ATM* mutations was verified by SIFT and PolyPhen online tools. Only mutations present in >10% of reads were considered for the PFS analysis (log-rank (Mantel-Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL recommendations).
Results: In the pre-therapy analysis, we identified 23 patients with one disrupted gene and 7 patients with two disrupted genes; the rest of the cohort (n=23) was devoid of the mutations (wt). The most frequently affected gene was *ATM* (15 cases; only mutations with predicted functional impact considered), followed by *SF3B1* (10 cases; hot-spot mutations), *NOTCH1* (7 cases; all deletion c.7541_7542) and *BIRC3* (5 cases; frame-shift mutations). We did not observe significant differences in PFS among the employed regimens: the medians were 16.5 months (m) for FCR (used in 30 patients; median: 4 cycles); 15 m for Q-FCR (15 patients; 4 cycles); and 14 m for BR (8 patients; 3.5 cycles); P=non-significant (ns). In univariate analyses of individual affected genes, we did not observe an adverse impact of mutations on PFS: *ATM*-mut median 19 m *vs* 14 m in wt patients; *SF3B1*-mut 19.5 m *vs* 16 m; *NOTCH1*-mut 32 m *vs* 15.5 m; *BIRC3*-mut 16 m *vs* 16 m (all analyses P=ns). In a more detailed analysis structured according to the type of *ATM* defect, patients with sole 11q- (the other *ATM* allele intact; n=13) manifested the shortest PFS of 11 m, followed by *ATM*-mutated patients (n=15; 19 m; P=0.1) and wt patients (n=24; 24 m; P=0.041). Analysis of clonal evolution in patients who relapsed (41 paired samples) revealed the following significant events: selection of *TP53* mutations in two cases (from 2.3% to 77%, and 5.4% to 64.5%) and *ATM* mutations in two cases (8% to 15% and wt to 18%), as well as more complex changes involving both increase and decrease of mutations in *BIRC3* gene in three patients.
Summary/Conclusions: Our pilot analysis with limited number of samples does not indicate adverse impact of studied mutations in rituximab-based regimens. Some relapsed samples showed quite distinct mutation profile. Supported by projects AZV 16-32743A, MUNI/A/1106/2016 and FNBr, 65269705.

BCR SIGNALLING PROFICIENT CHRONIC LYMPHOCYTIC LEUKAEMIA B CELLS ARE PRONE TO RITUXIMAB MEDIATED ELIMINATION IN VIVO

G. Pavlasova[1,2,*], M. Borsky[2], V. Svobodova[1,2], K. Musilova[1,2], K. Cerna[1,2], V. Seda[1,2], J. Osickova[2], Y. Brychtova[2], M. Doubek[2], S. Pospisilova[1,2], J. Mayer[2], M. Mraz[1,2]
[1]Molecular Medicine, CEITEC MU, [2]Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: Anti-CD20 monoclonal antibody rituximab (RTX) has improved clinical outcome of patients with CD20-positive B-cell malignancies, including chronic lymphocytic leukaemia (CLL). However, despite the fact that RTX has been clinically used for 20 years, the exact mechanism of its action remains largely unclear.
Aims: The aim of this study was to determine susceptibility of CLL cells' subpopulations to RTX.
Methods: Peripheral blood samples from CLL patients (N=17) were obtained and analysed before (day 0) and 24 hours (day 1) after RTX administration (375mg/m^2, single agent).
Results: It was described that CLL cells that interacted with stromal cells *in vivo* can be characterised by relatively weak cell-surface expression of chemokine receptor CXCR4 and high expression of activation marker CD5 (CXCR4^{dim}CD5^{bright}cells) (Calissano *et al*., 2011). We showed that these cells also have higher CD20 expression than CLL cells circulating in the peripheral blood without contact with immune niches (CXCR4^{bright}CD5^{dim}; Pavlasova *et al*., 2016). We hypothesised that the higher levels of CD20 on CXCR4^{dim}CD5^{bright} cells make them the primary target for RTX *in vivo*, since the cell surface CD20 expression associates with the RTX efficacy (Golay *et al*., 2001). We analysed blood samples obtained from CLL patients treated with RTX as a single agent and indeed, we observed that RTX preferentially and nearly completely eliminates the CXCR4^{dim}CD5^{bright} subpopulation after the first RTX dose (8.3% pre-RTX *vs* 2.1% post-RTX, P<0.0001). We further analysed BCR signalling proficiency of the CXCR4^{dim}CD5^{bright}CD20^{bright} subpopulation, since CD20 was proposed to play a role in BCR signalling. We observed that CXCR4^{dim}CD5^{bright} CLL cells have higher immunoglobulin (IgM) expression (~2-fold, P<0.005) which was coupled with higher responsiveness to BCR crosslinking with anti-IgM (P=0.005). Moreover, CXCR4^{dim}CD5^{bright} cells also have higher levels of CD19 (1.8-fold, P<0.0001), which is an important component of BCR complex that augments signal transduction. Furthermore, we demonstrated that CXCR4^{dim}CD5^{bright} cells have higher phosphorylation of several proteins involved in PI3K/BCR/NFkB signalling pathway (P<0.05) compared to CXCR4^{bright}CD5^{dim} cells obtained from the same patient. This led us to hypothesize that CD20 up-regulation on CXCR4^{dim}CD5^{bright} cells is likely of physiological importance for PI3K/BCR signalling. Indeed, we observed significant reduction in phosphorylation of tyrosine-protein kinases associated with PI3K/BCR signalling after silencing of CD20 by siRNA in B cells.
Summary/Conclusions: We showed that CXCR4^{dim}CD5^{bright} CLL subpopulation in peripheral blood of CLL patients has the highest surface levels of CD20 and is therefore preferentially and effectively eliminated by RTX. These CLL cells likely represent the most "aggressive" subclone of CLL cells since they have relatively high proliferative and BCR signalling capacity.

REGULATION OF BCR SIGNALLING IN CHRONIC LYMPHOCITYC LEUKEMIA: ROLE OF E3 UBIQUITIN LIGASE C-CBL

V. Martini[1,2], R. Molfetta[3], F. Severin[1,2], V. Trimarco[1], F. Frezzato[1,2], F. Raggi[1,2], L. Martinello[1], A. Visentin[1], E. Scomazzon[1], M. Facco[1,2], G. Semenzato[1,2], R. Paolini[2,3], L. Trentin[1,*]
[1]Department of Medicine, University of Padua, [2]VIMM, Venetian Institute of Molecular Medicine, Padua, [3]Department of Molecular Medicine, University of La Sapienza, Rome, Italy

Background: In normal B cells, the E3 ubiquitin ligase Cbl (c-Casitas B-lineage lymphoma) is involved in the ubiquitin-dependent Lyn degradation and in the down-regulation of BCR signalling. c-Cbl is activated by phosphorylation that releases c-Cbl from its autoinhibited structure by triggering a conformational change that leads to an enhanced transfer of ubiquitin from the E2 enzyme to the substrate proteins. Mutations in this RING/Linker region result in the loss of ubiquitin E3 ligase activity thus prohibiting lysosomal or ubiquitin/proteasome-mediated degradation of tyrosine kinases and thereby unleashing tyrosine kinase signaling. We reported that in Chronic Lymphocityc Leukemia (CLL) Lyn is over-expressed and is in an active conformation as integral component of an aberrant cytosolic multiprotein complex, associated with several proteins, such as Hsp90, HS1 and SHP-1L. In particular, Hsp90 appears tightly bound to cytosolic Lyn, thus stabilizing the aberrant complex and converting individual transient interactions into stable ones.
Aims: The accumulation of clonal B lymphocytes in CLL is mostly due to apoptosis resistance but also to proliferative activity. Abnormalities of molecules involved in signal transduction pathways are connected to CLL pathogenesis and a critical role has already been ascribed to B-cell receptor (BCR)-Lyn axis. Here, we investigated the expression and the role of c-Cbl in CLL B cells since in normal B cells is involved in the ubiquitin-dependent Lyn degradation and in the down-regulation of BCR signaling.
Methods: Blood samples were collected from 30 CLL patients and 15 controls. Untouched peripheral blood B cells were purified using the RosetteSep isolation kit for human B cells. We characterized c-Cbl total protein level and c-Cbl(Y700) by Western blotting. To evaluate the interaction between c-Cbl and Lyn in CLL

B cells we performed a co-immunoprecipitation assay, followed by Western blotting analysis, at steady state and after IgM (10μg/ml) stimulus. We also evaluated the interaction between c-Cbl and Lyn after treatment with 17-DMAG (500nM), a potent HSP90 inhibitor.
Results: We demonstrated that c-Cbl is overexpressed ($p<0.001$, Student's t test in CLL B lymphocytes with respect to normal B cells. We found that in neoplastic B cells c-Cbl did not co-immunoprecipitate with Lyn neither after BCR trigger. We obtained similar results when we treated neoplastic B lymphocytes with 17-DMAG to dissociate the Lyn-Hsp90 complex: after 1h, 2h and 4h of treatment we immunoprecipitated Lyn demonstrating that neither before nor after IgM stimulation c-Cbl interacts with this kinase. These results support the hypothesis that c-Cbl is not involved in Lyn turnover. Data obtained from 10 independent experiments showed that in CLL neoplastic cells the phosphorylation on Y700 increased after 5' and 10' of IgM stimulus, highlighting the involvement of c-Cbl in BCR signaling.
Summary/Conclusions: These preliminary results prompt us to investigate the role of c-Cbl in the development of neoplastic clone. In CLL cells c-Cbl is overexpressed with respect to normal B cells, and upon BCR engagement it undergoes Y700 phosphorylation. However, c-Cbl is unable to stably interact with Lyn suggesting an altered c-Cbl function that contribute to affect cell homeostasis.

ACTIVATION OF SHP-1/PP2A PATHWAYS TRIGGERS APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

F. Severin[1,2], E. Tibaldi[3], M.A. Pagano[4], F. Frezzato[1,2], V. Trimarco[1,2], V. Martini[1,2], F. Raggi[1,2], L. Martinello[1], M. Facco[1,2], G. Zagotto[4], G. Ribaudo[4], V. Pavan[4], L. Bordin[3], A. Visentin[1,2], F. Zonta[5], G. Semenzato[1,2], A.M. Brunati[3], L. Trentin[1,2,*]
[1]Department of Medicine, University of Padua, [2]Venetian Institute of Molecular Medicine (VIMM), [3]Department of Molecular Medicine, [4]Department of Pharmaceutical and Pharmacological Sciences, [5]Department of Biomedical Sciences, University of Padua, Padova, Italy

Background: CLL B cells inability to reach programmed cell death is due to intrinsic defect and extrinsic factors. Among the intrinsic fault there is the misregulation of the phosphorylation pattern. Reversible protein phosphorylation is a fundamental post-translational modification by which virtually all cellular events are regulated. The crucial players involved in this dynamic process are protein kinases and protein phosphatases, which are placed at the different levels of cellular signaling. The Src Family Kinase (SFK) Lyn is a key factor in the dysregulation of survival and apoptotic pathways of malignant B cells in CLL. One of the effects of Lyn's action is the spatial and functional segregation of the tyrosine phosphatase SHP-1 into two pools, one beneath the plasma membrane in an active state promoting pro-survival signals, the other in the cytosol in an inhibited conformation and unable to counter the elevated level of cytosolic tyrosine phosphorylation.
Aims: Because CLL is characterized by a high level of Lyn-dependent tyrosine phosphorylation in the cytosol, we focused our attention on compounds capable of directly or indirectly driving the activation of SHP-1 which in turn could counter the action of Lyn and induce cell demise. The goal is to discover new therapeutic strategies to defeat a still incurable disease as CLL.
Methods: B cells were collected from 37 CLL patients. Freshly isolated CLL cells incubated with increasing concentrations of nintedanib (0-24 μM) and MP07-66 *(2,2-diethoxyethyl{[4-(hexyloxy)phenyl]methyl})amine)* for 24 and 48 hours with/without a layer of Mesenchymal Stromal Cells (MSCs). Caspase dependence was demonstrated using the pan-caspase inhibitor z-VADfmk. CLL B cells viability was tested by Flow Cytometer with Annexin V/PI test. SHP-1 and PPP2Ac expression and phosphorylation were evaluated by Western Blotting.
Results: We performed *in vitro* phosphatase activity assays on the cytosolic pool of SHP-1 in the presence of increasing concentrations of nintedanib, a receptor tyrosine kinase inhibitor recently shown to trigger SHP-1 activity. Nintedanib treatment could activate the phosphorylated (at Ser591), and inhibited, form of SHP-1 and to induce apoptosis, depending on the caspase activation, after 24h and 48h at marked level. Interestingly, we recently demonstrated that Ser591 phosphorylation of SHP-1 could be dephosphorylated by PP2A. In this scenario, the restoration of PP2A activity by a fingolimod analogue devoid of immunosuppressive action, called MP07-66, and the subsequent dephosphorylation of PP2A substrates, was shown to trigger apoptosis, like nintedanib, in a caspase-dependent manner. Since our data suggest that the activation of either PP2A or SHP-1 triggered by specific small molecules caused stimulation of each other's activity, we treated CLL cells with nintedanib and MP07-66 together demonstrating an improved effect when used in combination. Similar results, in all the conditions, were obtained in presence of a MSC layer, showing the capability of these treatments to counteract the protective action of tumor microenvironment.
Summary/Conclusions: In conclusion, our findings indicate that phosphatase activators may represent a new weapon against this form of leukemia. Overall, these data corroborate the hypothesis that the inhibition of PP2A is central to CLL cell viability and that its activation is facilitated by the supportive action of SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

TARGETING NANOPARTICLES TO CHRONIC LYMPHOCYTIC LEUKAEMIA: EXPLOITING THE PROPERTIES OF CXCR4

C. Mccallion[1,*], A. Booth[2], J. Adams[3], K. Rees-Unwin[3], A. Peters[1], A. Pluen[4], S. Webb[1], J. Burthem[3]
[1]School of Chemistry, University of Manchester, Manchester, [2]School of Chemistry, University of Leeds, Leeds, [3]Institute of Cancer Sciences, [4]School of Pharmacy, University of Manchester, Manchester, United Kingdom

Background: Nanoparticle carriers of therapeutic agents ("drug delivery vehicles") can be used to deliver drugs to specific cells through the incorporation of a "targeting ligand". Targeting provides the therapeutic benefit of achieving high local drug concentrations while reducing off-target effects against other cells; the combined ligand/delivery vehicle system can also be manipulated to determine the uptake pathway or modulate biological effects. The CXCR4 chemokine-receptor is an attractive target for drug delivery vehicles. It is overexpressed in cancers including chronic lymphocytic leukaemia (CLL) (Domanska et al., 2013) and binding to its ligand (CXL12) may induce proliferation, survival or entry into protective cellular niches (Ganju et al., 1998). Targeted nanoparticles that can bind and antagonise CXCR4 could therefore allow specific drug delivery to cancer cells while simultaneously blocking CXCL12-induced chemoprotection.
Aims: A drug-design strategy was developed to synthesise and evaluate a novel CXCR4 targeting motif (BAT1) with structural similarity to Plerixafor, a CXCR4-antagonist in clinical use. A key design principle was to incorporate a polyethylene glycol (PEG) tether with a functional end-group to provide an attachment point for cargoes, particularly liposomes. The evaluation aim was to assess the effectiveness of BAT1 to deliver a chemotherapy cargo to CLL cells within an *ex vivo* culture system.
Methods: A three-step synthesis was used to generate BAT1 (Figure 1A); its structure and purity was confirmed using NMR, MS and HPLC. Bioactivity testing employed primary CLL lymphocytes. Assessments tested: CXCR4 binding-affinity (flow cytometric competition assays), cell-binding characteristics (immunocytofluorescence) and blockade of CXCL12-induced signalling (immunoblot). Initial targeting assessment used a fluorescent label (Cy5) conjugated to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.
Results: The binding affinity of BAT1 (Figure 1B) was demonstrated using competition assays (CXCL12, anti-CXCR4 ab, and the bis(cyclam) drug Plerixafor). The studies confirmed BAT1 had high affinity for CXCR4 receptors expressed on primary CLL cells. Immunocytofluorescence comparison with its native ligand confirmed binding of BAT1 to the CLL cell surface, while immunoblotting demonstrated blocking of CXCL12-induced downstream signalling (Figure 1C and 1D). The fluorescent moiety Cy5 was covalently linked to the PEG moiety as a test-cargo, demonstrating that binding affinity was retained in the presence of a cargo and that the drug competed for CXCR4 binding with related bis(cyclam) drugs. This work has been extended to attach BAT1 to liposomes, with present work optimising liposome characteristics for binding and uptake by CLL and the delivery of cytotoxic payload.

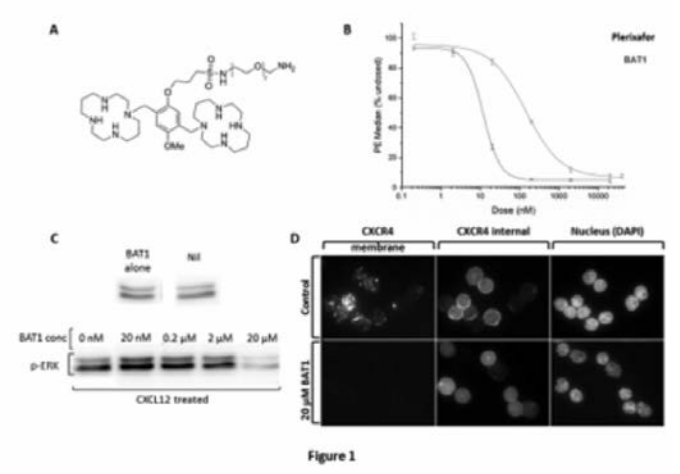

Figure 1

Figure 1.

Summary/Conclusions: A novel bis(cyclam) CXCR4 antagonist and targeting ligand – BAT1 – has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1

is readily attached to liposomes through the PEG moiety, which will allow chemotherapy delivery using stealth-liposomes (Allen and Cullis, 2013). Liposome size and composition will be used to drive pathway-specific uptake to different intracellular compartments. BAT1 therefore offers significant potential to enhance therapy in CLL.

THE ROLE OF THROMBOPOIETIN AS A TOOL OF IMMUNE MODULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA

S. Ringelstein-Harlev[1,*], M. Fanadka[2], N. A. Horowitz[1], T. Katz[1]
[1]Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus, [2]Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

Background: Thrombopoietin (TPO) is the major regulator of platelet production, synthesized mainly by liver cells. The TPO receptor (TPO-R) is known to be expressed on platelets, megakaryocytes and CD34$^+$ cells. It has been reported that patients with immune thrombocytopenic purpura, treated with TPO-R agonists, developed alterations in the T-cell repertoire and pattern of cytokine secretion from B- and T-cells. Thus, clinical activity of these agents could be attributed in part to immune modulation. In chronic lymphocytic leukemia (CLL), characterized by aberrant T-cell responses, high TPO serum levels coexist with low levels of TPO gene transcripts in the malignant cells. These observations could imply that TPO acts as an immune modulator in CLL.
Aims: The aim of the current study was to explore the role of TPO in T-cell modulation in CLL.
Methods: B-cells and CD4$^+$T-cells were isolated from peripheral blood mononuclear cells (PBMCs) of untreated CLL patients (Rai stages 0-IV) and healthy donors. TPO-R (CD110) expression on CD4$^+$ T-cells was estimated by FACS. CD4$^+$ T-cells were incubated with low-dose IL2 and TPO for 5 days and the percentage of CD4$^+$CD25^{hi}FOXP3$^+$ cells (Tregs) was assessed. T-cell proliferation was evaluated using CFSE staining after stimulation with anti-CD3/CD28 antibodies, high-dose IL2 and TPO for 5 days. Percentage of cells retained in G0 (non-proliferating pool) was assessed. CLL B-cells were activated with a TLR9 agonist (ODN) and TPO expression was assessed by Q-PCR.
Results: CD4$^+$ T-cells of CLL patients expressed significantly higher levels of TPO-R (CD110) compared to T-cells of healthy donors, with a mean fluorescent intensity of 764±148 and 498±206, respectively ($p<0.05$; n=6). Stimulation of patient-derived CD4$^+$ T-cells with TPO led to a 12% increase in the number of cells retaining in G0 (from7.5%±5.4 to 8.5%±6.4; $p<0.05$; n=8), whereas proliferation of healthy donor T-cells remained unaffected by TPO (11.5%±5.7 and 11.4%±5.7 of cells in G0; p=NS; n=6). Additionally, TPO stimulation resulted in a 24% increase of Treg levels in patient T-cells (from 2.1%±1.7 to 2.6%±1.7%; $p<0.01$; n=8). However, the Treg levels were not altered in healthy donor T-cells subjected to TPO (0.74%±0.7 and 0.74%±0.8; p=NS; n=5), which is similar to their proliferation response to this growth factor. To determine whether CLL cells could be the TPO source in this disease, TPO mRNA expression in the malignant cells was assessed, demonstrating a baseline ct value of 721±296, which significantly increased to 1033±342 ($p<0.05$; n=6) upon ODN activation.
Summary/Conclusions: In the current study, TPO is found to affect immune properties of CLL patient T-cells, inhibiting their proliferation and increasing Treg levels. These effects have been observed in patient T-cells only, which could be partly explained by higher levels of TPO-R expression revealed on patient T-cells compared to healthy donor cells. The elevated TPO mRNA expression in CLL B-cells could point to them as one of the possible sources of this growth factor in patient serum. Activation of TPO-R may represent a novel mechanism of T-cell inhibition in CLL.

E1009

TREATMENT WITH BCR INHIBITORS INCREASES ROR1 EXPRESSION IN CLL CELLS

J. Kotaskova[1,2,*], S. Pavlova[1,2], K. Plevova[1,2], J. Malcikova[1,2], O. Stehlikova[1], L. Poppova[1], H. Kockova[1], M. Doubek[2,3], V. Bryja[4], S. Pospisilova[1,2]
[1]CMBGT, Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, [2]Central European Institute of Technology (CEITEC), Masaryk University, [3]Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, [4]Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic

Background: Receptor Tyrosine Kinase-Like Orphan Receptor-1 (ROR1) expression on malignant B-cells is considered a promising target for therapy of CLL and other lymphoproliferative disorders. Recently published data suggest that combination of BCR inhibitor ibrutinib with ROR1 antibody cirmtuzumab can enhance treatment efficacy in CLL. Nevertheless, the variability in ROR1 expression during disease progression, therapy administration and relapse remains unknown.
Aims: In our study we aimed to i) detect ROR1 in CLL cells during different stages of the disease using flow cytometry and qRT-PCR with focus on patients undergoing therapy; ii) analyse changes in ROR1 expression within individual patients during the disease course.
Methods: CLL cohort consisted of 96 CLL patients (152 samples): 23 patients with stable disease, 16 patients with active disease prior first therapy intervention, 6 patients during first therapy, 13 patients in progression before second line treatment, 3 patients in complete remission, 10 refractory patients, 9 patients treated with ibrutinib, 16 patients treated with idelalisib. To monitor changes in ROR1 expression we tested serial samples from 5 CLL patients (median follow up 76 months (66-131), median number of sampling points 12 (5-18)). For surface ROR1 protein analysis we used 8-colour flow cytometry (modified MRD protocol: CD45/CD3/CD19/CD5/CD81/CD79b/CD22/ROR1) in all samples. To quantify *ROR1* mRNA expression changes within individual patients we performed qRT-PCR in separated CLL cells (>95% CD19+CD5+). CLL cells from samples in remission were separated immunomagneticaly (Whole Blood Anti-ROR1 MicroBead Kit, Miltenyi Biotec).
Results: Using multicolour flow cytometry we confirmed ROR1 antigen/protein presence on CLL cells in each analysed sample. The ROR1 antigen was detectable on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using qRT-PCR we detected significantly higher levels of *ROR1* mRNA in samples of treated patients ($p<0.01$). This observation was supported by analysis of *ROR1* mRNA expression in five patients tested consecutively in several time-points. We detected *ROR1* mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of *ROR1* mRNA level. In patients treated with ibrutinib or idelalisib we observed steep increase of ROR1 expression compared to patients treated with FCR regimen.
Summary/Conclusions: ROR1 protein remains detectable on CLL cells during disease course even in complete remission. *ROR1* mRNA levels are highly influenced by therapy administration especially in the case of treatment with BcR inhibitors.

Supported by grants AZV-MZ-ČR 15-29793A, 15-31834A, and 15-30015A, MUNI/A/1106/2016 and CEITEC 2020 (LQ1601) MŠMT ČR.

E1010

NORMAL SERUM PROTEIN ELECTROPHORESIS IDENTIFIES AN EXCELLENT PROGNOSIS GROUP AMONG IGHV MUTATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA, WITH A MEDIAN TFS OVER 18 YEARS

J. Chauzeix[1,2,*], N. Bargues[1], M.-P. Laforêt[1], M. Deveza[1], V. Combeau[1], V. Renat[1], E. Guérin[1], F. Trimoreau[1], N. Dmytruk[3], J. Feuillard[1], N. Gachard[1], D. Rizzo[1]
[1]Service d'hématologie biologique, CHU Limoges, [2]UMR7276, Université de Limoges, [3]Service d'hématologie clinique, CHU Limoges, Limoges, France

Background: Approximately 36% of patients with chronic lymphocytic leukemia (CLL) have abnormal serum protein electrophoresis (SPE), either with hypogammaglobulinemia or with monoclonal immunoglobulin (Ig) peak. In this study, we compared locally recruited patients with normal and abnormal SPE.
Aims: The aim was to identify prognosis parameters.
Methods: A total of 189 patients (132 abnormal SPE and 57 normal SPE) were studied. Diagnoses were performed between 1980 and 2015. Prognosis parameters investigated were IGHV mutation status, presence of SF3B1, NOTCH1 or BIRC3 mutations (determined by high throughput and Sanger sequencing), and cytogenetic abnormalities such as del17p, del11q, del13q and trisomy 12 (assessed by standard caryotype, FISH analysis and QMPSF).
Results: In this series, 73%, 19% and 8% of patients were at Binet stage A, B and C respectively, and 30% had a normal SPE at diagnosis. Ninety six percent of patients with normal SPE were at Binet stage A, *versus* 63% of patients with abnormal SPE (Chi2 test : $p<10^{-4}$). Median lymphocytosis at diagnosis was lower in patients with normal SPE (12,82 G/L *versus* 19,54 G/L in abnormal SPE, Fisher test : p=0,00169). Regarding genetic prognosis factors, we found that 58% of cases with normal SPE had a good prognosis profile (mutated IGHV and/or isolated del13q, with no other genetic abnormality detected), meanwhile 65,2% of patients with abnormal SPE exhibited at least one poor prognosis marker (unmutated IGHV, mutation of SF3B1, NOTCH1, del17p, del11q or trisomy 12, Chi2 test : $p<10^{-4}$). In patients with normal SPE, only 3,5% cases were SF3B1 mutated against 15,2% in case of abnormal SPE (Chi2 test : p=0,002). Among other strong differences, 10,5% patients with normal SPE had a trisomy 12 against 18,2% for abnormal SPE. Isolated del13q was found in 38,6% and 21,2% of cases with normal and abnormal SPE respectively. Mutated IGHV status was found in 65% in normal SPE and 56% with abnormal SPE. Compared to the whole series, IGHV repertoire analysis shows bias in IGHV1-2, and IGHV4-34 rearrangements, with decreases usage of IGHV3-21 and IGHV3-48. Treatment free survival was markedly increased in patients with normal SPE (median of 10,0 years *versus* 3,0 years for normal and abnormal SPE respectively, log rank test : $p<0,0001$). Moreover, while patients with mutated IGHV had a median TFS of 8 years (against 3 years for unmutated patients), those with normal SPE and mutated IGHV had a median TFS over 18 years. Patients with mutated IGHV and abnormal SPE had a

median TFS of 4 years (log rank test : p=0,0003). Thus, patients with normal SPE and IGHV mutated status constitute a group with excellent prognosis.
Summary/Conclusions: In conclusion, normal SPE was associated with good outcome with decreased accumulation of side genetic events (in particular, SF3B1 mutations). This analysis shows a bias in IGHV repertoire according to SPE status. These results also clearly suggest that patients with a normal SPE and mutated IGHV have an extremely quiet CLL natural history. This could be either due to the weaker activity of the disease and/or to the absence of adverse consequences of a concomitant paraprotein.

E1011

HSP70 EXPRESSION IS MODULATED BY ITS MASTER REGULATOR HSF1 VIA MAPKS AND PI3K/AKT/MTOR PATHWAYS IN CHRONIC LYMPHOCYTIC LEUKEMIA

F. Frezzato[1,2], F. Raggi[1,2], B. Accordi[3], S. Bresolin[3], F. Severin[1,2], V. Martini[1,2], V. Trimarco[1,2], L. Martinello[1], A. Visentin[1,2], S. Imbergamo[1], E. Scomazzon[1], M. Facco[1,2], F. Piazza[1,2], G. Basso[3], G. Semenzato[1,2], L. Trentin[1,2,*]
[1]Department of Medicine, University of Padua, [2]Venetian Institute of Molecular Medicine (VIMM), [3]Department of Women's and Children's Health, University of Padua, Padova, Italy

Background: The search for molecules involved in apoptosis resistance/increased survival of B cells from Chronic Lymphocytic Leukemia (CLL) is still ongoing since this disease remains not definitively understood. We recently found that the Heat Shock Protein of 70kDa (HSP70), expressed in response to a wide variety of stress signals and allowing cells to survive to lethal conditions, was particularly overexpressed in neoplastic B cells from CLL. Moreover, the Heat Shock Factor 1 (HSF1), the major responsible for the transcription of HSP70, is itself overexpressed in CLL and strictly correlated to HSP70. In response to stress, HSF1 becomes phosphorylated, forms homotrimers, binds DNA and activates heat shock gene transcription. HSF1 is regulated by a fine balance of activatory/inhibitory phosphorylations mediated by kinases belonging to pathways triggered by RAS (*i.e.* PI3K/AKT/mTOR and RAF/MEK/ERK).
Aims: Since HSP70 is overexpressed in CLL neoplastic B cells and most of "HSF1-phosphorylating actors" belong to signalling pathways taking part from RAS, being the PI3K/AKT/mTOR and the RAF/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells.
Methods: In a Reverse Phase Protein Array (RPPA) study, previously performedin B cells from 57 CLL patients and 11 healthy subjects, we assessed the activation/expression of key signalling proteins. Herein, we focused on HSP70, AKT-Ser473, mTOR-Ser244, GSK3a/b-Ser21/9, CDK2, CREB-Ser133, MEK1/2-Tyr217-221, ERK1/2-Thr202/Tyr204, NFkB-Ser536, p38MAPK-Thr180/Tyr182, SAPK-JNK-Thr183/Tyr185 and PDK1-Ser241. Cluster and separated analyses have been performed.
Results: We divided our patients in HSP70-high and HSP70-low considering as cut-off the value of the median of HSP70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HSP70. HSP70-high patients present high Akt-Ser473, an inhibitor of GSK3a/b that, in the inhibited form, prevents HSF1 inhibition. By contrast, HSP70-low patients have high MEK1/2-Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, p38MAPK-Thr180/Tyr182 which has been described to both activate and inhibit HSF1 at different sites, is overexpressed in those patients presenting low levels of HSP70.
Summary/Conclusions: These data would suggest that, in CLL, HSP70 expression is regulated by the modulation of HSF1 activity through the activation of one or the other way triggered by RAS. In particular, an activation of the PI3K/AKT/mTOR pathway leads, as result, to a higher expression of HSP70 while an activation of the RAF/MEK/ERK signalling rather results in HSP70 down regulation. The dissection of signalling pathways connected to HSP70-HSF1 axis in CLL will contribute to define the biology and understand the pathogenesis of this disease.

E1012

THE INTERPLAY BETWEEN TH17 AND TREGS: A NEW IMMUNOSUPPRESSIVE INSIGHT IN CHRONIC LYMPHOCYTIC LEUKEMIA

S. De Matteis[1,*], R. Napolitano[1], A. Lucchesi[2], D. Cangini[2], A. Cuneo[3], G.M. Rigolin[3], E. Volta[3], G. Musuraca[2]
[1]Bioscience Laboratory, [2]Hematology Unit, IRCCS Istituto Scientifico Romagnolo per lo studio e la cura dei tumori (IRST), Meldola, [3]Medical Sciences, University of Ferrara-Arcispedale Sant'Anna, Ferrara, Italy

Background: Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in the Western world and it is characterized by the clonal expansion of CD5 positive B cells. In CLL, different T cells dysfunctions have been described, probably related to the interaction with malignant B cells. TH17 and regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a fundamental part in inflammatory response and immune tolerance. However, their role in the immunopathogenesis of CLL has not yet been fully clarified.
Aims: The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL.
Methods: After obtaining the patient's informed consent, peripheral blood was collected from 30 untreated CLL patients and 30 age-matched healthy volunteers (HV). Cytokine production was evaluated before and after a 48 h culture of CD4+ T cells in complete medium with IL-6 (o/n), followed by a 5 h stimulation with PMA, Ionomycin and Monensin (PIM), or with *Candida Albicans*. For cytokine secretion analysis, stimulated CD4+ T cells were analyzed by human IL-17 and IL-10 secretion assay. IL-23 plasma levels were evaluated by ELISA. For the analysis of Tregs and their subsets, stimulated PBMCs were stained with anti-CD4 FITC, anti-CD25 APC-Cy7, anti-FoxP3 APC and anti-Tbet PE or anti-RORγt PE or anti-GATA-3 PE. Statistical analysis were carried out using the paired and unpaired two-tailed Student's t tests and confirmed with the non parametric Wilcoxon signed-rank test.
Results: In CLL patients we observed a reduced production of IFN-γ and IL-4, respectively from TH1 and TH2 and an increase of IL-17A from TH17, compared to HV. All the observed differences were statistically significant. We also evaluated the ability of CD4+ T cells to secrete IL-17A, IL-10 or both. We reported a statistically significant increase in the frequency of CD4+ IL-17A-producing cells in CLL patients compared to HV, whereas the percentage of IL-17A+/IL-10+ cells remained unchanged. In order to evaluate the functional effects of the observed alterations, we analyzed IFN-γ+ CD4+ T cells-mediated response after stimulation with *C. Albicans* for 48 h, with or without depletion of IL-17A-secreting cells. The frequency of IFN-γ-producing T cells resulted statistically significant increased in patients than HV before IL-17A-secreting T cells depletion. Conversely, after IL-17A+ CD4+ T cells depletion, we didn't observe significant differences in term of IFN-γ production. We also observed increased IL-23 plasma levels in patients compared to HV. In addition our data highlighted a significantly higher frequency of CD4+ CD25^{high}FoxP3+ cells (Tregs) in CLL samples, with a statistically significant increase in Tbet+ Tregs, RORγt+ Tregs and GATA-3+ Tregs subpopulations (Figure 1).

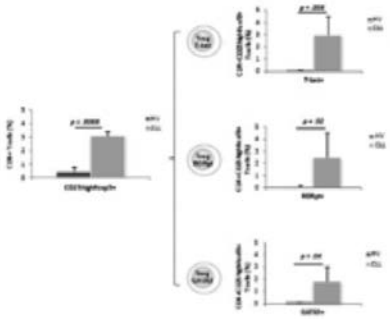

Figure 1.

Summary/Conclusions: Our results reported a down-regulation of IFN-γ and IL-4 producing T cells, associated to an increased frequency of Tregs and their subsets in CLL patients, probably trying to overcome the deficit of effector T cells. On the other hand, we observed a rise in IL-17A secreting T cells related to the increased IL-23 production by dendritic cells in order to restore TH17 pool, without changing the percentage of IL-17A+/IL-10+ cells. These data support the idea of the protective function of TH17 that show an effector and not a regulatory T phenotype. Starting from these observations, this study could pave the way to further researches and applications in the comprehension of the biological and regulatory mechanisms of TH17 and Tregs, supporting the study of a pioneering anticancer therapy in CLL.

E1013

LOW EXPRESSION OF CD25 IN CHRONIC LYMPHOCYTIC LEUKEMIA NOTCH1-MUTATED CASES INDEPENDENT OF CDK4/6 MISREGULATION

T.H. Chen Liang[1,*], A.M. Hurtado[1], M. Castillo[1], J. Muñoz-Ballester[1], B. Przychodzen[2], M.D. García-Malo[1], F. De Arriba[1], F.J. Ortuño[1], J.P. Maciejewski[2], V. Vicente[3], A. Jerez[1]
[1]Hematology and Oncology Department, Hospital Morales Meseguer,Centro Regional de Hemodonación. Universidad de Murcia, IMIB, Murcia, Spain, [2]Translational Hematology and Oncology Research Department, Cleveland Clinic, Cleveland, United States, [3]Hematology and Oncology Department, Hospital Morales Meseguer,Centro Regional de Hemodonación. Universidad de Murcia, IMIB,CIBERER, Murcia, Spain

Background: Recently, it has been shown that CDK6-mediated repression of CD25 is required for induction and maintenance of NOTCH1-induced T-cell acute lymphoblastic leukemia.
Aims: The aim of this study was to identify the NOTCH1 mutational status detected by deep sequencing in a cohort of 138 CLL patients and to correlate it with the immunophenotypic profile and CDK4 and CDK6 expression.
Methods: We performed targeted NGS sequencing of blood samples, collected at diagnosis, from 138 CLL patients. We designed a TruSeq Custom Amplicon

containing 13 genes and covering 28.099 bases. Paired-end sequencing was performed with MiSeq v2.2 chemistry, and a mean depth of 998 reads/base was obtained. Every patient underwent, at baseline, a flow cytometry characterization with a panel including (sIg)λ, (sIg)κ, CD19, CD5, CD11b, CD81, CD10, CD79b, CD29, CD38, FMC7, CD22, CD45, CD103, CD11c, CD25, ZAP70, CD11a, and CD24. CDK4 and CDK6 expression levels were quantified by RT-qPCR.
Results: With a median age of 66 y.o. (range, 31-89) and a slight male predominance, the median follow up time of our cohort was 43 months (24-104). We found that 38/138 (28%) patients harbored at least one mutation, with NOTCH1 (n=16, 12%), ATM (n=12, 9%), TP53 (n=9, 7%), and SF3B1 (n=8, 6%), as the most frequently mutated genes. Those patients with a NOTCH1 mutation showed a lower CD25 expression (24 mean fluorescence intensity units (MFIu)) than those without a mutation (43 MFIu), p=0.03. We could not validate the recently reported association between the presence of NOTCH1 mutations and a low expression of CD20. In our cohort, the MFI expression in NOTCH1 mutated and non-mutated patients was 163 and 146 units, respectively (p>0.05).We measured CDK4 and CDK6 expression in the CD19+ sorted fraction RNA of 7 NOTCH1 mutated cases and 11 non mutated cases, without finding significant differences (0.26 *vs* 0.27 for CDK6, 0.025 *vs* 0.022 for CDK4; p>0.5 in both cases).
Summary/Conclusions: We found a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inversed direction to that found in physiological conditions, has also been shown in the setting of NOTCH1-mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CDK4/6 expression, prompting further studies assessing CDK4 and CDK6 regulators.

González[1], J.-M. Hernández-Rivas[1]
[1]Cancer Research Center/Hospital Universitario de Salamanca, SALAMANCA, [2]Hospital Virgen Blanca, LEÓN, [3]Hospital del Bierzo, PONFERRADA, [4]Hospital Río Carrión, PALENCIA, [5]Hospital General, SEGOVIA, [6]Hospital Río Hortega, Valladolid, [7]Hospital Santa Bárbara, SORIA, [8]Hospital Clínico Universitario, VALLADOLID, [9]Hospital Juan Ramón Jiménez, HUELVA, [10]Hospital Miguel Servet, ZARAGOZA, [11]Hospital Virgen del Puerto, PLASENCIA, [12]Hospital Universitario Infanta Leonor/Universidad Complutense de Madrid, MADRID, Spain

Background: Next-Generation sequencing (NGS) studies have revealed a number of recurrently mutated genes in chronic lymphocytic leukemia (CLL). It is reasonable to argue that evaluation of the newly gene mutations as prognostic markers would help to improve prognostication of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with other prognostic markers associated with good prognosis.
Aims: To analyze the presence of mutations of a panel of genes by NGS and its prognostic impact in patients with CLL, focusing in the groups of patients with good prognosis characteristics.
Methods: Amplicon-based-NGS was performed using 454 platform in 147 CLL patients to evaluate the mutational status of 6genes (*TP53*, *NOTCH1*, *SF3B1*, *XPO1*, *FBXW7* and *MYD88*). Samples were obtained at diagnosis or before treatment in all cases. 70.1% were Binet A and 53% had 13q deletion (13q-). A cut-off 2% was applied to define variants. All the mutations were validated.
Results: 1. NGS analysis showed that 37.4% of CLL patients (55/147) showed mutations in any of the analyzed genes. The frequency of mutations was 16.3% for *NOTCH1*, 10.2% for *SF3B1,* 6.8% for *TP53*, 4.8% for *XPO1*, 3.4% for *FBXW7*, and 1.4% for*MYD88*.The presence of mutations in any of these genes except to *MYD88* (mutated CLL) was significantly associated with clinical progression (60.0% for mutated CLL *vs.* 38.2% for unmutated CLL; *P*=0.05). Interestingly, mutated CLL patients showed a shorter time to first treatment (TFT) than unmutated CLL patients (30 months *vs.* 88 months; *P*=0.006). By contrast, *MYD88* mutations were detected in CLL with mutated *IGHV* and 13q-. 2. Of note, 23.6% of the mutations had a mutational load of ≤15% and thus would not have been detected by capillary Sanger sequencing. CLLs with mutations in ≤15% of cells had also a shorter TFT than patients without mutations (18 *vs.* 88 months; *P*=0.018), and similar to CLL patients with mutations in >15% of cells (*P*=0.370). In addition, 14.5% of mutated CLL patients showed 2mutations.Patients with more than one mutation had a shorter TFT than CLL patients with one mutation (7 months *vs* 31 months). 3. In the group of CLL patients with Binet stage A, 32.8% of them showed mutations in any of the analyzed genes. Interestingly, CLL patients Binet A with mutations (except to *MYD88*) showed a shorter TFT than CLL patients without mutations (31 *vs* 131 months, P<0.001). Besides this, CLL with 13q- as the sole cytogenetic alteration and gene mutations had also a shorter TFT that unmutated 13q- CLL patients (*P*=0.002).
Summary/Conclusions: 1) CLL patients with mutations in *TP53*, *NOTCH1*, *SF3B1*, *XPO1* and *FBXW7* show a worse prognosis than CLL patients without mutations. 2) Gene mutations in *TP53*, *NOTCH1*, *SF3B1*, *XPO1* and *FBXW7* in a low percentage of the cells are associated with a shorter TFT. 3) Among CLL patients with good prognostic characteristics (Binet A and 13q-), gene mutations help us to define the prognosis of the patients.

ALTERED COMPLEX C5 IS ASSOCIATED WITH COMPROMISED COMPLEMENT ACTIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Braester[1,2,*], M. Barhoum[1], R. Michelis[1]
[1]Haematology, Galilee Medical Center, Naharyia, [2]Faculty of Medicine, Bar-Ilan University, Safed, Israel

Background: The therapeutic monoclonal antibodies used for the treatment of Chronic lymphocytic leukemia (CLL) mediate anti-tumor effects through several mechanisms: complement-mediated cytotoxicity (CDC), antibody-dependent cell-mediated cytotoxicity (ADCC), and phagocytosis. CDC efficacy thus depends on the expression level of the target B-cell antigen, the integrity of apoptotic cascades within tumor cells, the functional capacity of effector cells, and the availability and activity of the complement (C) system. Published data indicate deficiency of one C protein or more in most CLL patients, as well as additional factors that may affect C activity. The role of structural abnormalities of C complexes in affecting C function has not been investigated.
Aims: To study the structural integrity of circulating C complexes, focusing mainly on C5, and to establish its importance for C activity in CLL.
Methods: Blood samples were collected from 36 naïve CLL patients and 10 healthy controls (HC). Biochemical and haematological parameters, and CLL staging were recorded. The isoforms of two key C components, C3 and C5 were studied by Western blot analysis. The activity of the C system before and after in-vitro activation via the classical or alternative pathways was followed by the levels of C5b-9, the terminal product of C activation. C activation was also studied in combination with C5-deficient serum or after supplementation with normal C5. In-vitro activation data were associated with the presence of C5 isoforms.
Results: Differences in C5 pattern were found in some of the CLL patients. Specifically, the C5 complex that exists as a single protein band in all HC and in 56% of CLL patients appeared in 44% of the patients as a clear double-band. No clear differences were observed in C3 pattern in the patients. Higher basal levels of C5b-9 were found in CLL patients with abnormal pattern of C5 (3946±758 SEM ng/ml) compared with both HC (682±158 SEM ng/ml) and CLL patients presenting normal C5 pattern (2363±655 SEM ng/ml). In-vitro C activation via the classical pathway was inversely correlated with basal activity, and was significantly lower (p<0.03) in the CLL patients with altered C5 compared to HC and CLL patients with normal C5. In-vitro activation via the alternative pathway was similar in all subjects' groups. C activity in C5-deficient serum supplemented with 33% sera from patients with abnormal C5 was significantly lower compared to the activity observed after supplementation with serum from HC or from patients with normal C5. Activity after supplementation with normal C5 (commercial) was significantly lower in sera from CLL patients with abnormal C5 pattern compared to sera from the other subjects' groups.
Summary/Conclusions: The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complex structure of C5. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. The exact mechanisms by which abnormal C5 distracts the C activity need further clarification. Yet, the appearance of abnormal C5 in CLL patients with disturbed C activity bears the potential to develop a marker which will assist in identifying patients who are likely to be less responsive to future immunotherapy treatment due to compromised CDC. Development of such a marker may assist clinicians in refining and personalizing the immunotherapeutic approach, improving CDC and consequently the therapy results.

Background: Prognostic factors correlate with clinical outcomes, independent of treatment. B cell receptor (BCR) signaling pathway inhibitors can nullify the prognostic impact of some markers, such as *IGHV* mutation status.CpG-stimulated metaphase karyotype can identify clonal cytogenetic abnormalities in CLL that may not be seen with standard non-stimulated karyotype or by FISH. Complex cytogenetics, defined as 3 or more chromosome abnormalities in 2 or more metaphases was the highest-risk feature for shorter progression-free and overall survival in patients receiving ibrutinib for relapsed/refractory CLL. Complex karyotype is not uncommon among relapsed/refractory CLL cases, particularly those who previously received genotoxic chemotherapy.

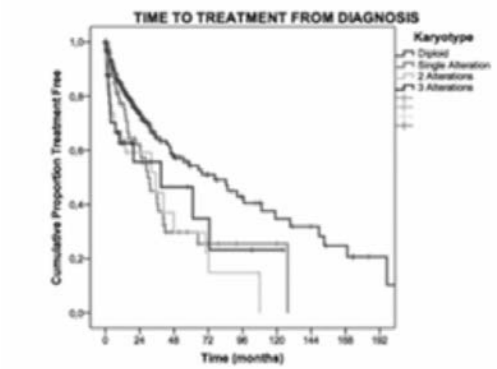

Figure 1.

Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naive CLL.

Methods: We evaluated 501 treatment-naïve patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-685 (20ug/ml), phorbol 12-myristate 13-acetate (PMA; 0.04ug/ml) and Pokeweed mitogen (PWM; 0.1ug/ml). Banding and analyses were by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype.The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table + Firgure).

Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as del17p, del11q, unmutated*IGHV* and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (p=.0005). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutated*IGHV*; 3 involved lymph node sites; and CD38 expression (>30%).

Summary/Conclusions: In conclusion, CpG-stimulated karyotype identified 1 or more clonal chromosome abnormality in nearly a third of untreated patients and was a significant independent prognostic factor for TTFT. Models for TTFT may be useful in identifying patients at high-risk for needing treatment sooner and thereby useful for early intervention clinical trials.

Background: In the last two decades, a plethora of clinical, serological and biological markers have been identified that are significantly associated with the prognosis of chronic lymphocytic leukemia (CLL) patients. Recent research has focused on the development of scoring systems capable of integrating the major prognostic parameters. A recent prognostic index called CLL International Prognostic Index (CLL-IPI), built on clinical, serological, and biological parameters (TP53 deletion and/or mutation, IGHV mutational status, β2M, clinical stage, and age) has been proposed and validated. Recently, a Barcelona-Brno CLL group, with the aim of simplifying the CLL-IPI, proposed a prognostic model comprising only two biomarkers (IGHV mutational status and FISH cytogenetics).

Aims: We performed a comparison of the CLL-IPI with the Barcelona-Brno prognostic model in an independent series of Italian and United States (U.S.) patients.

Methods: Databases from 4 Italian and 1 U.S. centers including roughly 3700 newly diagnosed CLL patients were used to compare the CLL-IPI with the Barcelona-Brno prognostic model. Baseline data regarding age, Rai stage, IGHV mutational status, β2M and fluorescence *in situ* hybridization (FISH)-detected cytogenetic abnormalities were available for 1299 cases. Del17p was used as the sole marker of *TP53* status. The CLL-IPI and the Barcelona-Brno prognostic model were calculated using the methods proposed. The accuracy of the prognostic models was assessed by the Harrell C index (an index of discrimination), the explained variation in mortality (an index combining calibration and discrimination), and the Akaike information criterion (AIC, an index comparing two non-nested prognostic models). The lower the AIC, the higher the prognostic accuracy of a predictive model.

Results: The median age of the 1299 patients was 63 years (range 27-92) with 61.3% males. The majority of patients had Rai stage 0 (57.9%). According to the CLL-IPI, 51.3% of patients were classified as low-, 28.7% as intermediate-, 16.2% as high-, and 3.8% as very high-risk. The 5-year OS probabilities were: 95% for low-risk, 89.9% for intermediate-risk, 70.1% for high-risk, and 32.8% for very high-risk cases (P<0.0001; Harrell C index=73%;P<0.001) (Figure 1A). According to the Barcelona-Brno prognostic model, 58.1% of patients were classified as low-, 31.8% as intermediate-, and 10.1% as high-risk. The 5-year OS probabilities were: 92.2% for low-risk, 83.6% for intermediate-risk, and 68.2% for high-risk cases (P<0.0001; Harrell C index=65%; P<0.001) (Figure 1B). The AIC showed the superiority of the CLL-IPI compared to the Barcelona-Brno prognostic model in predicting OS (CLL-IPI, AIC=3432.167 *versus* Barcelona-Brno prognostic model, AIC=3549.492). Accordingly, the explained variation in mortality provided by the CLL-IPI was 42% (P<0.001), a figure higher than that due to the Barcelona-Brno prognostic model

(21%,P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for mortality compared to that of the biomarkers-only prognostic model. Then, we also compared the ability of the two scores to predict TTFT in newly diagnosed patients. The Harrell C-index of the Barcelona-Brno prognostic model was 0.70 (P<0.001), lower than that of the CLL-IPI score (0.73,P<0.001). The AIC showed the superiority of the CLL-IPI compared to the Barcelona-Brno prognostic model in predicting TTFT (CLL-IPI, AIC=5960.503 *versus* biomarkers-only prognostic model, AIC=6010.929). Accordingly, the explained variation provided by the CLL-IPI was 33% (P<0.001), a figure higher than that achieved by the Barcelona-Brno prognostic model (28%,P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for predicting TTFT as compared to that of the Barcelona-Brno prognostic model.

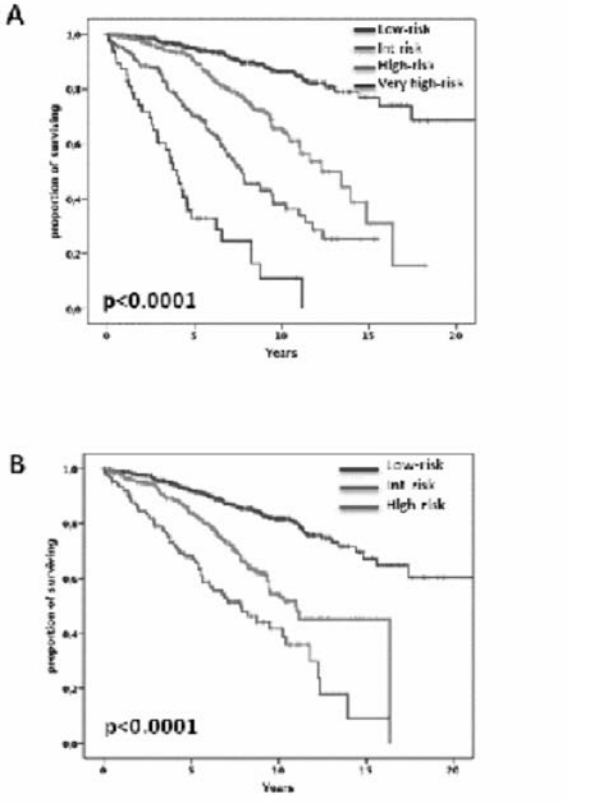

Figure 1.

Summary/Conclusions: Our results confirm the validity of both scores (CLL-IPI and biomarkers-only prognostic model) to predict survival and TTFT among patients with previously untreated CLL. Moreover, we have demonstrated that the CLL-IPI which combines clinical and serological data with biological parameters has a higher accuracy for predicting prognosis and TTFT of CLL patients than the Barcelona-Brno biomarkers-only prognostic model.

E1018

PRELIMINARY RESULTS OF S55746/BCL201 (A NEW BCL2 INHIBITOR) IN RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AND EFFECT OF CALIBRATED MODERATE MEAL ON THE PHARMACOKINETICS

V. Ribrag[1,*], M. Wermke[2], F. Morschhauser[3], S.T. Lim[4], G. Salles[5], I. Kloos[6], M. Becquart[6], A. Derreal[6], L. Kraus-Berthier[6], S. Pennaforte[6], J.-M. Michot[1], S. Stilgenbauer[7], J. Walewski[8], S. Le Gouill[9]
[1]Institut Gustave Roussy, Villejuif, France, [2]Universitätsklinikum Carl Gustav Carus, dresden, Germany, [3]CHRU - Hôpital Claude Huriez, Lille, France, [4]National Cancer Centre, Singapore, Singapore, [5]Hematology, Hopital Lyon Sud, Lyon, [6]Servier, SURESNES, France, [7]University of Ulm, Ulm, Germany, [8]Lymphiod Malignancies, Maria Sklodowska-Curie Memorial Institue and Oncology Centre, Warszaw, Poland, [9]Hematology, CHRU Nantes, Nantes, France

Background: BCL-2 is an anti-apoptotic protein overexpressed in chronic lymphocytic leukemia (CLL). BCL-2 is responsible for apoptosis machinery dysregulation and contributes to chemotherapy resistance. S55746/BCL201 is a novel, oral, selective BCL-2 inhibitor.
Aims: The current first-in-human study evaluates the safety and aims to establish the recommended phase 2 dose; main secondary objectives include evaluation of pharmacokinetics (PK), food effect, pharmacodynamics and preliminary activity in patients (pts) with relapsed or refractory CLL.
Methods: S55746/BCL201 as single agent is being investigated in a phase I (EUDRACT, NCT02920697), open label, multicenters, international dose escalation trial. S55746/BCL201 was initially administered in fasting condition, once daily (in 21-day cycle) until progressive disease (PD) or unacceptable toxicity. A tumor lysis syndrome (TLS) prevention protocol was implemented. After giving informed consent pts could receive 50 to 2000mg according to a modified version of the Continual Reassessment Method for dose allocation process. In the food effect part of the study, 7 non-Hodgkin's lymphoma patients received a film coated 200mg tablet under fasting condition (*i.e.* after 10-hour fasting period) and after a calibrated moderate meal the day after.
Results: As of February 2017, 12 CLL pts have been treated (median age 67 years [range 52-82]). On these 12 pts, 5 presented a bulky disease, 1 a 17p13 deletion, 4 a 11q deletion, and 1 a p53 mutation. CLL pts were dosed up to 700mg, with a median duration on treatment of 79 days. Median number of prior regimens in CLL pts was 4 (range 2-5). Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. The most frequent (≥2 pts) grade 3/4 adverse events (AEs) were neutropenia (n=2) and thrombocytopenia (n=2). AEs possibly related to the study drug were reported in 4 pts: neutropenia (n=2), neutrophil count decrease (n=1), fatigue (n=1), dyspnea (n=1), gingival bleeding (n=1) and left ventricular ejection fraction (LVEF) decrease (n=1). No clinical or laboratory TLS were reported. One patient in the 700mg cohort experienced a DLT (asymptomatic LVEF decrease grade 2 recovered within 2 weeks). At 700mg, a decrease in lymphocytes count from baseline (>50%) was observed in 3 out of 4 patients associated with a decrease in the sum of the product of the diameters of lymph nodes (from 23% to 40%). This decrease in lymphocytes count, started from cycle 1, and may be correlated with an induction of apoptosis in CLL cells (4 hours post first dose), detected by flow cytometry in CD19+/AnnexinV+ cells. Two CLL pts are ongoing after having completed their 3rd cycle; 10 pts have withdrawn from the study: 7 due to PD, 1 for lack of efficacy and 2 due to AE. The non-compartmental pharmacokinetic analysis of the food effect cohort (5 assessable pts) demonstrated that S55746/BCL201 PK is modified by the ingestion of a moderate meal (400-500 kcal with fat contributing to 150 kcal). The median Tmax was delayed from 1.5h to 4h when administered with food. Compared with fasting condition, Cmax and AUC increased by approximately 6-fold following a moderate meal. Based on these results, a protocol amendment to the clinical trial has been implemented in order to further investigate the administration with food in a new dose escalation.
Summary/Conclusions: S55746/BCL201 monotherapy showed first signs of activity across the tested dose levels with an acceptable safety profile so far. Based on PK food interaction results, dose escalation in the fed state has started.

E1019

INCREASED VIRUS-SPECIFIC IMMUNE RESPONSES PARALLELED BY A PNEUMOCOCCUS-SPECIFIC-IMMUNODEFICIENCY STATE AND HYPOGAMMAGLOBULINEMIA: ALREADY EMERGE IN HIGH-COUNT MONOCLONAL B LYMPHOCYTOSIS PRIOR TO CLL

I. Criado[1,*], S. Muñoz-Criado[2], A. Rodríguez-Caballero[1], W.G. Nieto[1], A. Romero-Furones[3], P. Fernández-Navarro[4], M. Alcoceba[5], T. Contreras[6], M. González[5], A. Orfao[1], J. Almeida[1]
[1]Department of Medicine, Cancer Research Center (IBMCC, CSIC-USAL), [2]Service of Microbiology, University Hospital of Salamanca, [3]Centro de Atención Primaria de Salud Miguel Armijo, [4]Centro de Atención Primaria de Salud de Ledesma, [5]Service of Hematology, [6]Service of Biochemistry, University Hospital of Salamanca, Salamanca, Spain

Background: Patients diagnosed with chronic lymphocytic leukemia (CLL) display a high incidence of infections, due to an associated immunodeficiency state that includes hypogammaglobulinemia. Even more, it has been recently shown that the earlier stages of disease, *i.e.* high-count monoclonal B lymphocytosis (MBL^{hi}), subjects also have increased risk for infection.
Aims: To evaluate the status of the humoral immune response in CLL at different disease stages, as well as in pre-leukemic MBL^{hi} and MBL low count (MBL^{lo}) cases, *vs* healthy controls, through quantitation of soluble plasma levels of specific antibodies against ubiquitous and pulmonary infection-associated pathogens.
Methods: A total of 249 subjects (119 males/130 females; aged 68±11y) including 91 healthy donors, 71 CLL-like MBL^{lo}, 29 CLL-like MBL^{hi} and 58 CLL cases (32 Binet A, and 26 Binet B/C patients) were studied. Detection of clonal CLL(-like) B cells was performed by high-sensitive 8-color flow cytometry. Quantification of plasma antibody isotypes and specific immunoglobulins against CMV (cytomegalovirus), EBV (Epstein Barr Virus), influenza virus and *S.pneumoniae* were performed by nephelometry and commercial ELISA kits, respectively. Individuals who had received vaccination against Influenza and/or Pneumococo were excluded from the analysis of the immunoglobulin-specific titers against the corresponding pathogen, respectively. Plasma CMV and EBV DNA load was measured using commercial kits.
Results: Total immunoglobulin (Ig) titers tended to decrease with disease progression, independently of the isotype. In contrast, specific IgM and IgG titers against CMV, EBV and Influenza virus did not vary among groups, with the

exception of VCA-EBV IgG titers, that were higher in CLL *vs* the other groups. Strikingly, the IgG levels for the three viruses tended to gradually increase, from healthy individuals to stage B/C CLL. These findings were more pronounced ($p<0.05$) for IgG and to a lesser extend also for IgM, when the ratios between the virus-specific Ig/total Ig titers of the same isotype were calculated, except for Influenza-specific IgG, that showed the same trend but without statistical significance. Regarding CMV DNA load, only 3/177 individuals -1 MBL^{hi} and 2 CLL- were found to be positive (below the limit of quantitation), while EBV DNA load was detected in plasma from 7/191 (all being Binet A CLL) at median levels of 3.6 copies/ul. In contrast to the virus-specific Igs, IgG plasma levels against *S.pneumoniae* progressively diminished through progression of the disease, in parallel to the overall lower gammaglobulin levels.

Summary/Conclusions: Both MBL^{hi} and CLL patients present relatively high levels of specific Ig against human host viruses in parallel to progressively lower levels of anti-*S.pneumoniae* antibodies, which might reflect (asymptomatic) chronic reactivation of humoral immune responses against host viruses and progressively decreased protection against other microorganisms, denoting a severe pathogen-specific humoral immunodeficiency state not reflected by the overall plasma immunoglobulin levels. Alternatively, these results might point out a potential role of ubiquitous viruses in the pathogenesis of the disease. Further analyses are necessary to establish the potential relevance of such asymptomatic humoral immune responses against host viruses in the expansion of the tumor B-cell clone and progression from MBL to CLL.

E1020

AN EXTENSIVE MOLECULAR CYTOGENETIC CHARACTERIZATION IN HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA IDENTIFIES KARYOTYPE ABERRATIONS AND TP53 DISRUPTION AS PREDICTORS OF OUTCOME AND CHEMOREFRACTORINESS

G.M. Rigolin[1,*], L. Formigaro[1], M. Cavallari[1], F.M. Quaglia[1], E. Lista[1], A. Urso[1], E. Guardalben[1], S. Martinelli[1], E. Saccenti[1], C. Bassi[2], L. Lupini[2], A. Bardi[1], E. Volta[1], E. Tammiso[1], A. Melandri[1], M. Negrini[2], F. Cavazzini[1], A. Cuneo[1]
[1]Scienze Mediche, Azienda Ospedaliero Universitaria Arcispedale S. Anna, [2]Department of Morphology, Surgery and Experimental Medicine, and "Laboratorio per le Tecnologie delle Terapie Avanzate" (LTTA),, University of Ferrara, Ferrara, Italy

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, running an indolent course in some patients and a clinically aggressive course in others. Risk assessment is important in clinical practice and prediction of outcome and response to treatment is very useful in an era in which several chemoimmunotherapy combinations and effective mechanism-driven treatments are available.

Aims: We investigated whether an extended genetic characterization including mutational screening by next generation sequencing (NGS) and karyotype analysis could allow for a refinement of our capability to predict outcome in newly diagnosed CLL patients with high-risk features, as defined by the presence of unmutated IGHV gene and/or 11q22/17p13 deletion by FISH and/or TP53 mutations.

Methods: 101 patients were included in this study. TP53 disruption was defined by the presence of 17p13 deletion by FISH and/or TP53 mutation by NGS. Cytogenetic analysis was performed using CpG-oligonucleotide DSP30. Each patient was categorized according to the following classification: favorable group (isolated 13q14 deletion or normal karyotype), unfavorable group (deletions of 11q22 or 17p13, or complex karyotype, ie, at least 3 chromosome aberrations); intermediate group (all other karyotypic abnormalities). A cut-off of 98% homology to the germline sequence to discriminate between IGHV mutated and unmutated cases. Mutational screening was performed with Ion Torrent PGM NGS platform on 20 CLL-related genes by using a 5% cut off.

Results: Cytogenetic analysis showed favorable findings in 30 patients, unfavorable in 34 cases and intermediate in 36 cases. A complex karyotype was present in 21 patients. By NGS, 95 somatic mutations were observed in 56/101 (55.4%) cases; 80 missense mutations, 5 nonsense mutations and 10 frameshit deletions. 16 cases (15.8%) showed mutations in the TP53 gene, 11 (10.9%) in the NOTCH1 gene, 11 (10.9%) in the SF3B1 gene, 8 (7.9%) in the ATM gene, 5 (4.9%) in the BIRC3 gene, 5 (4.9%) in the PTEN gene, 4 (4.0%) in the MYD88 gene, 4 (4.0%) in the BRAF gene, 4 (4.0%) in the POT1 gene, and 18 (17.8%) cases in the remaining 11 genes. 26/56 (46.4%) mutated patients presented two or more mutations. The presence of mutations was associated with unmutated IGHV status ($p=0.040$) and the complex karyotype ($p=0.047$). TP53 disruption correlated with the presence of ≥2 mutations by NGS ($p=0.001$) and a complex karyotype ($p=0.012$). By multivariate analysis an advanced Binet stage ($p<0.001$) and an unfavorable karyotype ($p=0.001$) predicted for a shorter time to first treatment (TTFT), while TP53 disruption ($p=0.019$) and the unfavorable karyotype ($p=0.028$) predicted for a worse overall survival (OS). A shorter time to chemorefractoriness (TTCR) was associated with TP53 disruption ($p=0.001$) and unfavorable karyotype ($p=0.025$). Patients with both unfavorable karyotype and TP53 disruption presented a dismal outcome (median OS and TTCR of 28.7 and 15.0 months respectively).

Summary/Conclusions: A comprehensive analysis of chromosomal aberrations and gene somatic mutations in high-risk CLL showed that the cytogenetic profile was independently associated with a shorter TTFT, OS and TTCR. Since karyotyping using novel mitogens may contribute to the refinement of prognosis in high-risk CLL patients, the introduction of this technique in future CLL trials seems warranted to identify those patients that could be ideal candidates for consolidation treatment or novel treatment combinations.

E1021

SHOULD CLL-IPI BE USED TO ASSESS OVERALL SURVIVAL OF EVERY CLL PATIENT? A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Molica[1,*], D. Giannarelli[2], R. Mirabelli[1], L. Levato[3]
[1]Hematology-Oncology Department, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, [2]Biostatistic Unit, IRCCS Regina Elena, Roma, [3]Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy

Background: A weighted grading approach based on five independent prognostic factors (i.e, *TP53* status, IGHV mutational status, ß2-microglobulin, clinical stage and age) has been used by an international Working Group to generate the chronic lymphocytic leukemia international prognostic index (CLL-IPI). Although the robustness of CLL-IPI has been confirmed in independent validation studies it remains unclear whether CLL-IPI has the greatest validity and should be preferred to guide clinical decision in CLL.

Aims: To shed light on this important research question, we conducted a systematic review which includes all published studies which used CLL-IPI to prognosticate overall survival (OS) in CLL.

Methods: A comprehensive MEDLINE search using "CLL-IPI" as Medical Subject Headings (MESH) allowed to identify at the cut-off time of February the 28, 2017 "seven hits" with only "four" citations considered pertinent. The search extended to the conference proceedings of annual meetings of ASH, EHA and ASCO of last two years recognized "three" additional citations.

Results: Overall 6720 patients from seven evaluable studies were suitable for the present analysis aimed at assessing the impact of CLL-IPI on OS. The majority of patients (4953 or 73.7%) came from studies of external validation of CLL-IPI while 17% (1192) and 8.5% (576) had been used to generate (training set analysis) and to internally validate the model. Patient distribution into the four risk categories of CLL-IPI was heterogeneous thus reflecting the CLL phase (*i.e.*, at diagnosis, at time of first treatment and at relapse) of patients within different studies. Accordingly, patients diagnosed as having low-, intermediate-, high- and very high-risk CLL-IPI ranged respectively between 9% and 58%, 25% and 39%, 14% and 52% and 2% to 9%. Next we evaluated the 5-year OS of patients stratified into each of the four CLL-IPI risk groups using either "Q" or "I^2" test to assess the heterogeneity across different studies. The 5-year survival probability was 91% for low-risk group (95% CI, 90-91%; Q=55.2; P< 0.00; I^2, 87%), 80% for intermediate-risk group (95% CI, 79-82%; Q=49.36; P<0.00; I^2, 86%), 60% for high-risk group (95% CI, 57-62%; Q=42.78; P<0.00; I^2, 84%) and 32% for very high-risk group (95% CI, 27-38%; Q=18.1; P=0.01; I^2, 67%).

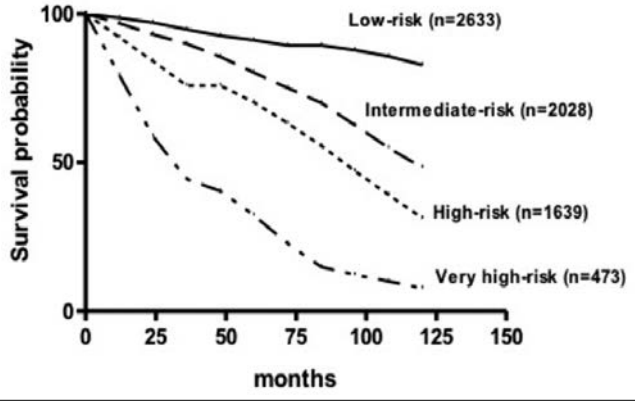

Figure 1.

Summary/Conclusions: In this comprehensive review and meta-analysis of studies thus far published on CLL-IPI we confirmed the value of this novel model to predict OS whatever the CLL phase (fig 1). The prognostic impact of CLL-IPI needs an extensive validation in patient cohorts receiving therapy with B-cell receptor or bcl-2 inhibitors. Nonetheless, in a study of relapsed/refractory CLL included in this analysis the PI3K-inhibitor idelalisib was not able to overcome the impact of CLL-IPI risk categories on OS.

E1022

IBRUTINIB FOR CHRONIC LYMPHOCYTIC LEUKEMIA: IMPACT OF THE CANADIAN YOU&I™ PATIENT SUPPORT PROGRAM ON TREATMENT ADHERENCE

A. Peters[1,*], J. Wiernikowski[2], S. Barker[3], M. Mahler[4], S. Luker[5], A. Lodick[5]

[1]University of Alberta, Endmonton, [2]Juravinski Hospital and Cancer Centre, Hamilton, [3]Janssen Inc., Toronto, Canada, [4]Janssen Research & Development, Raritan, [5]Human Care Systems Inc., Boston, United States

Background: Oral anticancer medications (OAMs) present several advantages compared with intravenous cytotoxic chemotherapy, including greater convenience for the patient. However, OAMs require that a patient be actively involved in regular drug administration over an extended period of time (Schneider SM, *et al.* Semin Oncol Nurs. 2011;27(2):133-141). Adherence to OAMs significantly impacts patient outcomes; poor adherence may result in inferior survival and outcomes, higher hospitalization rates, treatment resistance, and increased healthcare costs (McCue DA, *et al.* Pharmacotherapy. 2014;34(5):481-494). The Canadian YOU&i™ patient support program (PSP) was developed to improve adherence to long-term ibrutinib therapy using research-proven techniques for promoting positive behavioral changes, *i.e.* cognitive behavioral therapy, psycho-social support, and a nurse coaching component. Results from the program are presented below.
Aims: To evaluate patient adherence to ibrutinib, and patient and physician satisfaction with the YOU&i™ PSP
Methods: Using evidence-based literature reviews and global/local market research, various patient-centered barriers to treatment adherence were identified. Risk for non-adherence was calculated using the Morisky Medication Adherence Scale© score, which informed nurse coaching frequency. Adherence was delineated by prescription refill compliance. Patient and physician questionnaires were used to gauge satisfaction with the YOU&i™ PSP.
Results: As of 20 January 2016, a total of 903 patients with CLL were enrolled in the YOU&i™ PSP. A total of 552 patients were included in the adherence analysis. Of these, 86% opted in to receive the nurse coaching component. At 2 months from treatment initiation, patients who received nurse coaching demonstrated an adherence rate of 92.3%, as compared with 63.5% for patients who did not receive nurse coaching (95% CI, 17.5-41.0; p <0.0001). At 3 months the adherence rates were 89.9% *vs* 60.8% (95% CI, 17.5-41.4; p <0.0001). By 9 months, adherence rates were 81.7% *vs* 71.1% (95% CI, -4.4 to 28.4; p =0.141). At study conclusion, 12 month adherence rates were 76.6% *vs* 72.2% (95% CI, -18.9 to 32.4; p =0.715). Discontinuation rates were similar in all patients, regardless of nurse coaching status at 9 and 12 months. Patients reported satisfaction rates of >90% in surveys conducted at both 3 months and 12 months of program enrollment. Of physicians surveyed at 3 months, 96% reported that the YOU&i™ PSP was helpful in supporting patient needs.

Figure 1.

Summary/Conclusions: The current analysis provides insight into adherence patterns of patients on long-term ibrutinib treatment. These results are consistent with the literature showing that PSPs like the YOU&i™ PSP can help to improve adherence rates (Schneider SM, *et al.* J Adv Pract Oncol. 2014;5(3):163-172). The information obtained from long-term adherence data can help to inform future trials examining patterns of adherence with OAMs. Nurse coaching may be helpful in supporting early adherence by addressing side effects that occur more frequently at treatment initiation. Moreover, changes in disease or health status that arise over the first 12 months of therapy may provide information that allows a PSP to adapt to patients' evolving needs over the treatment journey. A better understanding of long-term adherence patters may allow programs such as the Canadian YOU&i PSP™ to target adherence support more precisely, thereby optimizing patient outcomes.

E1023

TREATMENT AND 17P DELETION TESTING PATTERNS IN COMMUNITY PRACTICE FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN THE UNITED STATES

T. Kapustyan[1,*], H. Keim[1], B. Meissner[1], L. Zhang[1], D. Jiang[1]
[1]AbbVie Inc., North Chicago, United States

Background: CLL is the most common type of leukemia in adults in the US. Traditionally, chemotherapy - and chemo-immunotherapy (CIT) have been the treatment mainstay. Historically, CLL patients (pts) with high-risk genetic features (e.g., 17p deletion (del(17p)) have poor prognosis and few treatment options. Over the past few years, oral-targeted therapies have been approved in the US for CLL pts, including those positive for del(17p).
Aims: This study used an electronic health record database to characterize treatment and del(17p) testing patterns in the first 2 lines of therapy (LoT) for CLL pts initiating treatment between 2011–2016. The association between del(17p) testing and utilization of targeted therapies was also explored.
Methods: This was a retrospective observational study in CLL utilizing a large, longitudinal, demographically and geographically diverse database of US cancer pts (Flatiron Health 12/2016). An analytical cohort of pts treated at community practice sites who initiated 1st LoT after Jan 2011 was developed. Two sub-cohorts of pts who initiated 1st LoT before and after 2014 were also identified reflecting the approval timeline of oral-targeted therapies in the US.
Results: As of Dec 2016, 3,140 pts with CLL were included in the broad Flatiron Health CLL cohort. The results of this analysis are based on the analytical cohort that included 1,700 pts who initiated 1st LoT during 2011–2016, of which 1,134 (66.7%) pts initiated therapy after 2014. Second LoT was initiated in 622 pts during 2011-2016, with 472 (75.9%) initiations occurring after 2014. Average age at CLL diagnosis was 66.9 years; 63.2% of pts were male; 70.2% were Caucasian. Over 2011–2016, the rate of genetic testing by cytogenetics or fluorescence *in situ* hybridization (FISH) before initiation of 1st LoT was 67.4%. The rate of del(17p) specific testing before 1st LoT was 59.1% (an increase from 38.9% in 2011 to 64.4% in 2016). Among those who were tested before 1st LoT, 12.5% tested positive for del(17p). In the sub-cohort of pts who initiated 1st LoT after 2014, ibrutinib monotherapy replaced fludarabine, cyclophosphamide and rituximab (R) combination as the 3rd most frequent (13.0%) 1st LoT in pts with CLL, after bendamustine/rituximab (BR) combination (29.8%), and rituximab (R) monotherapy (17.7%). In contrast, ibrutinib became the most common (43.9%) 1st LoT in newly diagnosed CLL pts with del(17p), followed by BR (24.5%) and R (7.1%). 36.6% of pts initiated 2nd LoT by December 2016. The three most common treatment sequences from 1st LoT to 2nd LoT were CIT to B-cell receptor pathway inhibitor containing therapy (16.4%), CIT to CIT (14.0%), and immunotherapy (IT) to IT (12.4%). Overall, the utilization of oral-targeted therapies has steadily increased since 2014, and multivariate analyses indicate that the presence of del(17p) is strongly associated (OR=8.7 and 2.8 for 1st and 2nd LoT, respectively) with this choice once these agents became available in 2014.
Summary/Conclusions: Considerable treatment pattern changes were observed for CLL pts in the US community practice due to the adoption of newly approved targeted therapies. Presence of del(17p) is strongly associated with choosing a targeted therapy regardless of LoT. Future research is needed to determine how differences in pt and disease characteristics and cytogenetic testing patterns influence treatment decisions and associated outcomes.

E1024

SINGLE-AGENT IBRUTINIB *VS* REAL WORLD TREATMENT FOR PATIENTS WITH TREATMENT-NAÏVE (TN) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): AN ADJUSTED COMPARISON OF RESONATE-2™ WITH THE CLLEAR AND LYON-SUD DATABASES

M. Doubek[1,*], E. Bachy[2], M. Spacek[3], L. Baseggio[2], R. Urbanova[4], H. Besson[5], J. Diels[5], J. Garside[6], N. Healy[7], W. Iraqi[8], E. Callet-Bauchu[2], L. Smolej[9], G. Salles[2]
[1]Department of Internal Medicine – Hematology and Oncology, University Hospital, Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [2]Hospices Civils de Lyon, Université Claude Bernard, Centre Hospitalier Lyon-Sud, Pierre Bénite, France, [3]1st Department of Internal Medicine – Hematology, General Faculty Hospital, Prague, [4]Department of Hemato-oncology, University Hospital, Olomouc, Czech Republic, [5]Janssen EU HEMAR Statistics & Modelling, Beerse, Belgium, [6]Janssen EMEA HEMAR, High Wycombe, United Kingdom, [7]7Janssen-Cilag EMEA Medical Affairs, Dublin, Ireland, [8]Janssen Pharmaceuticals, Paris, France, [9]94th Department of Medicine – Hematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic

Background: The phase 3 RESONATE-2™ study demonstrated significant improvement of progression-free survival (PFS) and overall survival (OS) with ibrutinib (ibru) *vs* chlorambucil (chl) in TN (aged ≥65 years) CLL patients. In the absence of direct comparison of single-agent ibru with other frequently used treatments in this patient population, additional comparative evidence against standard of care as observed in clinical practice can provide useful insights on the relative efficacy of ibru.
Aims: To investigate the relative treatment effect on PFS and OS for ibru *vs* real world (RW) treatment in daily clinical practice in TN CLL patients by adjusted comparison of patient-level data from RESONATE-2™ *vs* RW data from the CLLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases.
Methods: CLLEAR holds medical records for CLL patients from seven academic centers across the Czech Republic. Lyon-Sud database holds medical records for CLL patients from the academic French hospital Lyon-Sud. Patients initiated on CLL frontline therapy were selected from CLLEAR and Lyon-Sud using the same inclusion-exclusion criteria as for RESONATE-2 (excluding patients with age<65 and with del17p positive status). PFS and OS were com-

pared between ibru and RW treatment using patient-level data from RESONATE-2™ (n=136) and pooled patient-level data from the two cohorts. To adjust for differences in patient characteristics between the trial population and both cohorts, a multivariate Cox proportional hazards model was fitted on patient-level data to estimate the hazard ratio (HR) for ibru *vs* RW treatment, with age, sex, disease stage (based on RAI/BINET), and deletion 11q presence/absence included as covariates.

Results: Median age at treatment initiation for CLLEAR (n=418) and Lyon-Sud (n=110) was 73 and 71 years, respectively, *vs* 73 for Ibru patients from RESONATE-2™. The proportion of male patients was 63% in CLLEAR and 57% in Lyon-Sud *vs* 65% in RESONATE-2™. The median follow-up was 35.7 months (mo) for Lyon-Sud and 16.8 mo in CLLEAR *vs* 28.1 mo for RESONATE-2™. Adjusted HR for ibru *vs* physician choice in CLLEAR and Lyon-Sud were 0.23 [95% CI: 0.14, 0.39] and 0.25 [0.14, 0.43] for PFS, and 0.29 [0.11, 0.79] and 0.39 [0.18, 0.83] for OS, respectively. Fludarabine+cyclophosphamide+rituximab (FCR; n=117), bendamustine+R (BR; n=91), Chl alone (n=43), Chl+R (n=45), and other R-containing regimens (n=154) were the most commonly used treatment regimens across both RW cohorts. Older age, male gender, advanced disease stage and del11q positive status were independent risk factors for PFS and OS. The adjusted HRs (pooled estimates) for ibru *vs* the two most commonly used regimens were 0.30 [0.17-0.53] (FCR) and 0.33 [0.16-0.68] (BR) for PFS, and 0.44 [0.20-0.95] (FCR) and 0.33 [0.13-0.83] (BR) for OS (**Figure 1**). Estimates of HR *vs* regimens in the cohorts were consistent across both databases.

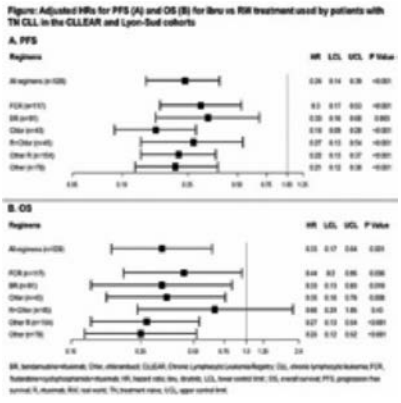

Figure 1.

Summary/Conclusions: This adjusted comparison of patient-level data from RESONATE-2™ with RW data from CLLEAR and Lyon-Sud demonstrates ibru to be more effective compared with RW treatment, with a 4.1-fold improvement in PFS and a 3-fold improvement in OS. When comparing ibru with the most commonly used RW treatments, statistically significant benefits for ibru were consistently observed *vs* all treatment regimens on PFS and for most comparisons on OS. These results further support the existing evidence that ibru significantly improves PFS and OS *vs* common regimens used in TN CLL settings, and has important implications for clinical practice.

E1025

CHARACTERISTICS, TREATMENT, AND OUTCOMES OF ≥80 YEAR OLD PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) ENROLLED TO PROSPECTIVE TRIALS OF THE GERMAN CLL STUDY GROUP

O. Al-Sawaf[1,*], J. Bahlo[1], K. Fischer[1], C. Herling[1], M. Hoechstetter[2], A. Fink[1], J. von Tresckow[1], P. Langerbeins[1], P. Cramer[1], S. Stilgenbauer[3], C. Wendtner[2], B. Eichhorst[1], M. Hallek[1], V. Goede[1]
[1]Department I of Internal Medicine, German CLL Study Group, University Hospital of Cologne, Köln, [2]Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Hospital Munich-Schwabing, Munich, [3]Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: People over 80 years are the fastest growing age group in western populations. Clinical management of ≥80 year old patients (pts) with CLL remains a challenge due to the very limited amount of data currently available for this age segment. Two retrospective studies reported observational data on characteristics, treatment, and outcomes of ≥80 year old pts not enrolled in a clinical trial (Bairey et al., Meunier et al.). Comparably little is known about ≥80 year old pts who were treated for CLL within clinical trials, however.
Aims: To study the characteristics, treatment, and outcomes of pts aged ≥80 years who received their first therapy within prospective trials of the German CLL Study Group (GCLLSG).
Methods: Trial populations of seven clinical trials of the GCLLSG (CLL1, CLL5, CLL7, CLL8, CLL9, CLL10, CLL11; total N=3552) were reviewed and screened for pts ≥80 years at frontline treatment. Clinical, laboratory, and genetic data of identified pts were pooled. Time-to-event data were analysed by Kaplan-Meier methodology. Independent prognostic factors for survival were identified by multivariate analysis using Cox regression modelling with stepwise selection procedures.
Results: Among 3552 reviewed GCLLSG trial participants, 152 were aged ≥ 80 years at initiation of firstline treatment. A majority of these pts were identified from CLL11 (n=132) while the remaining were from CLL1 (n=3), CLL5 (n=1), CLL7 (n=3), CLL8 (n=2), CLL9 (n=9), and CLL10 (n=2). Median age was 82 years (range 80-90). Concomitant diseases were present in 99% of the pts and median cumulative illness rating scale (CIRS) score was 8 (0-18). Median creatinine clearance was 46 mL/min (range 17-99 mL/min). Identified genomic aberrations were 13q deletion as a sole abnormality in 27%, trisomy 12 in 18%, 11q deletion in 9%, and 17p deletion in 16% of pts. IGHV was unmutated in 69% of the pts. Distribution of CLL-IPI risk groups was as follows: 6% low, 19% intermediate, 61% high, and 14% very high. Most pts had Binet stage B (36%) or C (43%). Chemoimmunotherapy with chlorambucil plus obinutuzumab (CLB-OB) or chlorambucil plus rituximab (CLB-R) was administered to 61 (40%) and 56 (37%) pts, respectively. Remaining pts received chlorambucil alone (CLB, n=19), fludarabine (F, n=10), fludarabine/cyclophosphamide (FC, n=1), fludarabine/cyclophosphamide/rituximab (FCR, n=2), or bendamustine/rituximab (BR, n=3). Rates of grade 3 or 4 neutropenia and infections were 35% and 13%, respectively. Premature treatment discontinuations occurred in 15% of cases and were mostly due to adverse events. The total overall response rate was 92% with 13% complete remissions. Median observation time for all pts was 40.7 months. Median progression-free survival (PFS) and treatment-free survival (TFS) were 17.2 and 32.3 months, respectively. A total of 47 pts (31%) received at least one further line of treatment. Median overall survival (OS) was 48.3 months, with adverse events (22%) and progressive CLL (16%) being the most frequent causes of death. Standardized mortality ratio was calculated and showed a 1.99 (CI 1.54-2.53) increased risk of death as compared to an age- and sex-matched general population. Independent prognostic factors for OS were 17p deletion and elevated serum thymidine kinase.

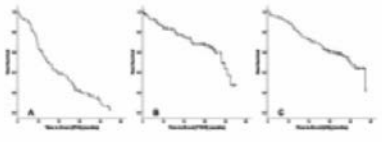

Figure 1.

Summary/Conclusions: Findings suggest that antileukemic therapy (including chemoimmunotherapy) is feasible and efficacious in ≥ 80 year old pts with CLL. However, such pts are stll highly underrepresented in clinical trials and even with modern treatment live shorter than age-matched controls of the general population. Broader recruitment of these pts to prospective trials and evaluation of targeted therapies therefore appears imperative to improve outcome of CLL in this age segment.

E1026

THE ROLE OF CD200 IN THE DIAGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA

A. Mora[1,2,*], E. P. Vicente[1,2], C. Cuellar[1,2], R. Bosch[1,2], L. Blanco[3], R. Martino[2], J. M. Ubeda[3], J. Sierra[1,2], C. Moreno[1,2], J. Nomdedeu[3]
[1]Laboratory of Oncology/Hematology and Transplantation, Institute of Biomedical Research, IIB Sant Pau, [2]Department of Hematology, [3]Laboratory of Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Clinic, morphologic, immunophenotypic and genetic features are the basis for the diagnosis of B-cell malignancies. It is considered that the diagnosis of CLL requires the presence in peripheral blood of >5x10^9/L monoclonal B lymphocytes with a distinctive immunophenotype (*i.e.* SmIg^{weak}, CD5$^+$, CD19$^+$, CD23$^+$). Based on immunophenotypic characteristics, Matutes et al devised in 1994 a immunophenotypic score based on a few markers (CD5$^+$, CD23$^+$, FMC7$^-$,SmIg^{weak}and CD22^{weak}) each one of them receiving a score of 1 if present or 0 if absent. A total score of 4 or 5 is typical of CLL whereas those cases scoring 0 or 1 correspond to other B-cell malignancies, mostly lymphomas. Nevertheless, clinical and immunophenotypic features of CLL may overlap with other B-cell malignancies. CD200 has been described as a marker potentially useful to distinguish CLL from other CD5$^+$B-cell malignancies.
Aims: The aim of this study was to analyze whether the addition of CD200 to the Matutes score improves the diagnostic accuracy of CLL.
Methods: We prospectively assessed the immunophenotype of 99 peripheral blood samples of patients with suspected lymphoproliferative disorders between November of 2015 and January of 2017. Immunophenotyping was performed using a Canto Flow Cytometer (Becton Dickinson) and samples were stained with routine combinations plus CD200. The Matutes Score was calculated as follows: FMC7, CD22 and CD79b were considered score 1 in CLL when the positive cells were <30%, CD5 and CD23 were considered score 1 when the positive cells were ≥30%. The cut-off used for CD200 was calculated by Receiver Operating Characteristics (ROC). CD200 was scored as 1 when the positive cells were >96%. Mean Fluorescence Intensity Ratio

(MFIR) was calculated as a relative expression between MFI positive population and MFI negative population. McNemar´s test was used to assess statistical significant differences in accuracy among individual markers and scoring systems. The treating physician made the final diagnosis of the different B-cell malignancies according to IWCLL and WHO criteria. Logistic regression including sensitivity, specificity and accuracy values, were used to evaluate statistical differences in diagnosis precision between different combinations of markers as well as individual markers.

Results: Flow cytometry analysis was performed in 99 patients, including 62 cases with a diagnosis of CLL (62.6%) and 37 cases with a "non-CLL" diagnosis (37.4%). Matutes score was 4-5 in all CLL cases and ≤3 in "non-CLL" cases. CD200, CD23 and CD5 were the most consistent markers for CLL (90.3%, 96.8% and 100.0% of sensitivity respectively). Moreover, CD79b and FMC7 had also a good discriminant value (80-85% sensitivity). For "non-CLL" cases the most reliable markers were SmIg, FCM7 and also CD200. The analysis of the accuracy is shown in the table. Of note, CD200 as a single marker was found to be a reliable marker for distinguishing CLL and "non-CLL" cases (90.9%; p<0.001; 90.3% sensitivity, 91.9% specificity) showing a significantly higher accuracy than CD5, CD23 and SmIg as individual markers (p<0.001). The accuracy of CD200 did not vary when comparing% of positive cells and MFIR. In contrast, the accuracy for SmIg significantly increased from 67.7% to 78.8% when using MFIR values (according to the cut-off established by ROC curves), being lower in CLL than in "non-CLL" cases (71.0% *vs* 86.5%, p<0.001). Finally, the addition of CD200 to the Matutes score system and using a cut off ≥4, improved its accuracy from 88.9% (95% CI: 88.2-95.6) to 98.0% (95% CI: 94.7-100.0) and showed a better sensitivity.

Table 1.

Marker	Score punctuation				CLL vs "Non-CLL" % (95% CI)*	p-value*	CLL vs "Non-CLL" % (95% CI)Δ	p-valueΔ
CD200	Negative	0	Positive	1	90.9 (84.7-97.1)	<0.001	90.9 (84.7-97.1)	<0.001
FMC7	Negative	1	Positive	0	85.9 (78.5-93.2)	<0.001	90.9 (84.7-97.1)	<0.001
CD79b	Negative	1	Positive	0	84.8 (77.3-92.4)	<0.001	88.9 (82.2-95.6)	<0.001
CD5	Negative	0	Positive	1	82.8 (74.9-90.8)	>0.05	83.8 (76.1-91.6)	<0.001
CD23	Negative	0	Positive	1	82.8 (74.9-90.8)	<0.001	87.9 (80.9-94.8)	<0.001
SmIg	Weak	1	Moderate/Strong	0	67.7 (58.0-77.4)	<0.001	76.8 (67.9-85.6)	<0.001

* % of positive cells; Δ MFIR

Summary/Conclusions: These results confirm CD200 as a valuable marker in the diagnosis of CLL

E1027

COMPARISON OF CHROMOSOME BANDING ANALYSIS AND GENOMIC MICROARRAY TECHNIQUES FOR THE DETECTION OF COMPLEX KARYOTYPES IN CHRONIC LYMPHOCYTIC LEUKEMIA

Background: Well-established poor prognostic factors in chronic lymphocytic leukemia (CLL) include deletions in 11q22 and 17p13 (del*ATM* and del*TP53*) by FISH. Genomic complexity detected by either chromosome banding analysis (CBA) or genomic microarray techniques, but underestimated by FISH, predicts an impaired outcome in CLL. Of note, none of these techniques is still routinely performed and standard criteria for risk stratification based on genomic complexity are lacking.

Aims: 1. To assess the complexity detected by genomic arrays in patients with complex karyotype by CBA; 2.To compare both methods regarding the number and type of aberrations detected in order to categorize patients based on genomic complexity.

Methods: A total of 24 CLL patients with complex karyotype (≥3 abnormalities, CK) by CBA were included [Median age: 73; 15 males (63%)]. Median time from diagnosis to CBA/microarray analysis was 3 months (range, 0-160), and 4 patients (16%) had received prior treatment. The cohort was enriched in del*ATM* and del*TP53* (37% and 42%, respectively). DNA from peripheral blood mononuclear cells or CD19+ lymphocytes was hybridized to Cytogenetics Whole-Genome 2.7M (n=2) or CytoScan HD (n=22) array, results were analyzed with Chromosomal Analysis Suite Software (Affymetrix). Number, size and type of aberrations detected were compared between techniques.

Results: A median of 3.5 aberrations (range: 3-9) were detected by CBA, being significantly lower than the copy number abnormalities (CNA) identified by microarrays (median 5, range: 1-28; P=0.018). The median size of the CNA was 5.4Mb (range: 0.1-174Mb). Current recommendations for microarray analyses suggest that only CLL known abnormalities and CNA >5Mb should be considered for clinical interpretation (Schoumans et al, 2016). When applying this cut-off, 42% of the initially detected CNA (74/177) were omitted and no significant differences in the number of abnormalities by each technique were found (P=0.334). CNA <1Mb did not involve any chromosomal altered region in the corresponding karyotype. Thus, their omission probably would not affect the stratification based on complexity. In contrast, most of the CNA between 1 and 5Mb involved small CNA associated to apparently balanced translocations by CBA, and in some cases revealed a higher genomic instability than the previously recognized by CBA (*i.e.* multiple deletions defined as a single one or a monosomy by CBA). Indeed, four cases showed chromothripsis not detected by CBA which has been associated with impaired outcome (Salaverria et al, 2015). Of note, genomic microarrays failed to detect some balanced translocations or subclonal aberrations by CBA, which probably were represented in a minor proportion of the sample but expanded during CBA culture. Thus, eight patients (21%) could only be considered complex by CBA, as by microarray analyses <3 CNA were detected. The present study is ongoing; additional cases have been collected in order to statistically assess the clinical impact on survival of the complexity detected by microarrays.

Summary/Conclusions: 1. The number of chromosomal abnormalities detected in CLL patients differs if assessed by CBA or genomic microarrays. 2. The current 5Mb cut-off to define clinically relevant CNA should be revised, as it could underscore genomic instability (contiguous small deletions, chromothripsis). 3. More studies should be performed to establish standard criteria for prognostic stratification of CLL patients based on genomic complexity consistent with the results from both techniques.

E1028

ABNORMAL SERUM FREE LIGHT CHAINS RATIO ASSESSMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: A SIMPLE YET POWERFUL TEST CORRELATING WITH CLINICAL OUTCOME AND MINIMAL RESIDUAL DISEASE

F. Durrieu[1,*], M. Le Bouar[1], F. Bijou[2], A. Schmitt[2], J. Blanchi[1], G. Etienne[2]
[1]Laboratory of hematology, [2]Hematology Department, Institut Bergonie, BORDEAUX, France

Background: An abnormal serum Free Light Chain (sFLC) ratio has been shown to be significantly associated with poor outcome in chronic lymphocytic leukemia (CLL) Yegin ZA et al, Eur J Haematol 2010, suggesting that this parameter may discriminate different biological subgroups.

Aims: As the technic is easily implementable in routine lab and cost effective, we evaluated the sFLC levels (kappa + lambda) and kappa/lambda (K/L) ratio in CLL patients in this prospective study. The relationship between abnormal sFLC levels (K+L) and/or K/L ratio, minimal residual disease (MRD) assessed by flow cytometry (FCM) and disease evolution was evaluated.

Methods: Diagnosis was confirmed by 10-color FCM immunophenotyping of blood lymphocytes on a Navios (Beckman Coulter). Serum FLC kappa and lambda chains were measured by nephelemetry using the Freelite™ immunoassay. The normal free kappa chains level was defined as within the range of 3.3-19.4mg/L, and the normal lambda chains level within the range of 5.71-26.30mg/L. A normal sFLC kappa/lambda (K/L) ratio was therefore defined as between 0.26 and 1.65 (a ratio above 1.65 indicating an excess of kappa light chain, and a ratio below 0.26 indicating an excess of lambda light chain). The cumulative level of kappa plus lambda (K+L) was also evaluated. Most patients received combined chemo-immunotherapy or entered clinical trials whenever possible. The ROC methodology was used to establish the best cut-off value of sFLC ratio level to discriminate treated patients from those who remained treatment-free.

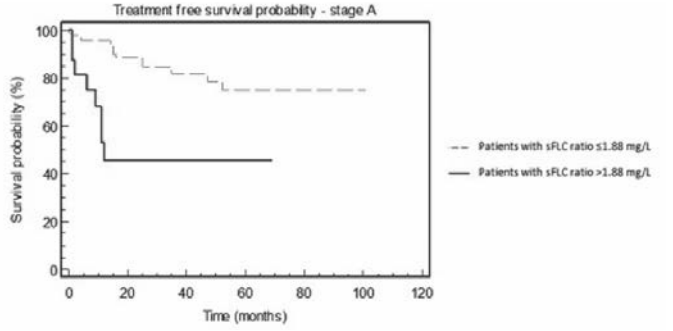

Figure 1.

Results: Main patients characteristics are detailed [N=147, M/F:75/72, 111 in early stage disease, Del 17p in 11 patients and Del11q in 15]. Median age was

69 years (range 34 to 86). Ninety patients were untreated during the follow-up period. Median follow-up duration was 30 months (range 0 to 101). Furthermore, sFLC measurement was assessed in 57 patients who progressed during the study and required treatment according to international guidelines. ROC curve analysis determines cut-off level of K/L ratio at 1.88. Abnormal sFLC was observed at diagnosis in 50.9% (N=29) of all treated patients. The mean ± SD ratio of sFLC in the untreated patients group and in the treated patients group was 1.51±2.08 and 2.80±3.75 respectively (p=0.0082). Considering the sFLC levels (kappa + lambda), the mean±SD in the untreated patients group and in the treated patients group was 29.1±17 and 53.0±41.9 respectively (p<0.0001). Treatment systematically induced a modification of the sFLC K/L ratio. Interestingly, after treatment completion, the persistence of an abnormal sFLC K/L ratio was associated with positive MRD determined by FCM with a 82% specificity and a 95% positive predictive value. Moreover, median time to treatment income for patients in early stage disease with ratio >1.88 was 12 months while it is not reached in those with ratio ≤1.88 (p<0.0001) (figure 1).

Summary/Conclusions: In this study we confirm the value of sFLC K/L ratio determination as a technically simple, standardized and cost-effective test to improve risk stratification of patients with low risk CLL at diagnosis, at the end of the treatment and during follow-up. Determination of the sFLC K/L ratio during the follow-up of treated patients provides additional information regarding the response to therapy in patients with an abnormal K/L ratio. In this study, persistence of an abnormal sFLC K/L ratio after treatment was strongly associated with positive MRD and could serve as a predictive as well as a prognostic biomarker for residual disease detection and clinical outcome.

E1029

PLATELET FUNCTION ASSAYS FOR STRATIFICATION OF BLEEDING RISKS IN CLL PATIENTS ON IBRUTINIB TREATMENT

E. Nikitin[1,*], E. Dmitrieva[1], A. Ignatova[2], A. Poletaev[2], D. Polokhov[2], A. Fedotov[2], E. Seregina[2], A. Pshonkin[2], M. Panteleev[2], V. Ptushkin[1]
[1]Outpatient department for hematology oncology and chemotherapy, S.P.Botkin hospital, [2]Molecular hemostasis laboratory, National Scientific and Practical Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

Background: Ibrutinib therapy in chronic lymphocytic leukemia (CLL) is associated with frequent bleeding complications, explained by inhibition of BTK, which mediates downstream signaling of GPVI and GPIb receptors in platelets. Detailed characterization of platelet functional impairment can help predict and possibly prevent severe bleeding on ibrutinib. Here we investigate platelet functional activity in CLL patients before initiation of ibrutinib and at different time points during treatment.

Aims: A longitudinal study on the impact of ibrutinib on platelet function, severity and frequency of bleeding.

Methods: Forty-three patients with relapsed and refractory CLL and 10 healthy donors were included in the study. Platelet functional activity was characterized by flow cytometry before and after activation with SFLLRN plus collagen-related peptide. Levels of CD42b, CD61, CD62P, PAC1, annexin V binding, and mepacrine release were determined. Aggregation with collagen, ADP and ristocetin were measured. All tests were performed before initiation of treatment, at weeks 2, 4, 8 and at 6 months. Bleeding complications were scored using ITP-specific Bleeding Assessment Tool.

Results: Among 43 CLL patients, 29 (67%) were men, the median age was 65 (range 31 to 83 years). Four patients with del (17p) received ibrutinib as a first line. In 39 previously treated patients the median number of prior treatments was 3 (range, 1-6). Del17p or TP53 mutation was found in 11 (25%) patients. Only 1 patient received anticoagulant and antiplatelet drugs. Median duration of ibrutinib treatment was 8.2 months (range 2.2-10.9). At least one bleeding episode occurred in 23 patients (53%). Among patients with bleeding, 14 (61%) had grade 1 events, 7 (30%) had grade 2 and two (9%) had grade 3 events. Bleeding frequency decreased with time on ibrutib; only 4 patients still had bleeding complications after 6 months. The patients with bleeding had significantly lower mean platelet count that those without (120 *versus* 170 thousands per microliter, P<0.0001) and higher lymphocytosis (74 *versus* 45, P<0.05). Their activation of integrins in response to stimulation was greatly impaired (9% *versus* 26%, P<0.0001; while the 95% confidence interval for healthy controls 63-137%), and there was significant difference in procoagulant activity as well (2% *versus* 5%, P<0.01; normal range is 7-35%). Importantly, the integrin activation allowed risk stratification: a person with more than 9% integrin activation had less than 10% risk to develop bleeding while the one with less than 9% integrin activation had a risk of more than 40%. There was no difference in dense- or alpha-granule release between the patient groups, and these indicators remained in their normal ranges. There were also significant differences in aggregation assay with ADP (25±16% *versus* 36±18% for bleeding and non-bleeding patients, p<0,001), collagen (38±19% *versus* 53±20%, P<0.001), and ristocetin (53±22% *versus* 62+20%, P=0.02). Interestingly, the patients with bleeding had negative correlation of the ADP-induced aggregation with leukocyte level.

Summary/Conclusions: Both classic aggregation assays and flow-cytometry-based techniques demonstrate impaired platelet function in the bleeding CLL patients compared with non-bleeding ones. The level of integrin activation appears to be the most sensitive and able to identify patients with different bleeding risks.

E1030

HYPOGAMMAGLOBULINEMIA IS A STRONG PREDICTOR OF TIME TO FIRST TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA

G. Reda[1], R. Cassin[1,*], G. V. Levati [2], B. Fattizzo[2], V. Mattiello[2], D. Giannarelli[3], W. Barcellini[1], A. Cortelezzi[2]
[1]Oncohematology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico of Milan, Italy, [2]Oncohematology Department, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Italy, Milan, [3]Regina Elena National Cancer Institute, Rome, Rome, Italy

Background: Management of chronic lymphocytic leukemia (CLL) dramatically improved since the introduction of novel therapies. Rarely patients requires treatment at diagnosis and approximately a third of patients will never require therapy. Predictive and prognostic factors are well known (IGHV, del11q, del17p, *TP53*); CLL-IPI score including age, clinical stage, beta2microglobulin, IGHV and deletion 17p and/or *TP53* mutation has been recently validated. It identifies 4 risk groups with significantly different time to first treatment (TTFT) and overall survival (OS). Hypogammaglobulinemia (HYPO) is a typical feature of CLL, with an incidence of 20-60% at diagnosis and a relationship with infections occurrence. Prognostic significance of HYPO at diagnosis has not been extensively evaluated in terms of OS and TTFT. Only IgG serum levels have been reported to be associated with TTFT but no data are available on other immunoglobulin classes (Ig).

Aims: To evaluate the impact of HYPO and single Ig classes on TTFT in a retrospective cohort of CLL patients and to assess the relationship between HYPO and CLL-IPI.

Methods: We retrospectively evaluated 698 consecutive CLL patients diagnosed at our Institution from 1983 till 2016. Data from laboratory, biological analysis and clinical stage were collected. We also evaluated immunoglobulin (Ig) status (*i.e.* IgG, IgM and IgA) at diagnosis and calculated CLL-IPI. HYPO was defined basing on our laboratory cut-offs (IgA 70mg/dl, IgG 700mg/dl, IgM 40mg/dl). However, as no recognized prognostic/predictive Ig cut off has been reported to date, we aimed to identify a prognostic threshold for each Ig class.

Results: From 698 patients assessed, 410 cases were evaluable for Ig values at diagnosis. IgA levels were lower than 70mg/dl in 17,4%, IgG lower than 700mg/dl in 22,2%, and IgM lower 40mg/dl in 33.7%. Forty-six percent of patients presented deficit of at least one Ig class, while 7.8% of patients had all Ig low. Each Ig deficit was related with a shorter TTFT with the following hazard ratios (HRs): 2.09 (1.45-3.03) for IgA (P<0.0001), 1.58 (1.10-2.27) for IgG (P=0.008) and 1.52 (1.09-2.13) for IgM (P=0.01) (Figure 1, A-B-C). However, only IgA deficit maintains statistical significance in multivariate analysis [HR 1.59 (1.08-2.35)]. A prognostic threshold for each Ig class was identified maximizing the differences in TTFT and the following values were obtained: 80mg/dl for IgA, 410mg/dl for IgG and 18mg/dl for IgM (Figure 1, D-E-F). Considering CLL-IPI, 186 patients presented IPI 0-1, 99 had IPI 2-3, 32 patients IPI 4-6, and 12 patients had IPI 7-10. Even in our series, CLL-IPI separated four risk groups with different TTFT and OS, suggesting that our cohort may be suitable to evaluate new prognostic factors. As regards the relationship between HYPO and CLL-IPI, we observed a correlation with IgA levels, using our laboratory cut-off. Moreover, we found a relationship among CLL-IPI and both IgA and IgM values, when using the newly validated Ig cut-off. Finally, CLL-IPI was a stronger prognostic factor for TTFT than HYPO in our analysis. However, the addition of IgA deficit to CLL-IPI appears to further improve CLL prognostication.

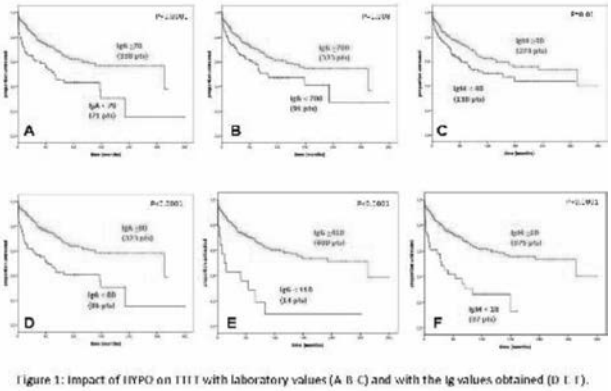

Figure 1: Impact of HYPO on TTFT with laboratory values (A-B-C) and with the Ig values obtained (D-E-F).

Figure 1.

Summary/Conclusions: In conclusion, HYPO significantly impacts on CLL prognosis. Moreover, even if CLL-IPI has a stronger prognostic value for TTFT compared to HYPO, the addition of IgA deficit appears to further improve CLL prognostication.

E1031

CLL: IS LYMPHOCYTE DOUBLING TIME (LDT) A RELEVANT PROGNOSTIC PARAMETER IN THE ERA OF PROGNOSTIC BIOMARKERS?

T. Baumann[1,*], J. Delgado[1], P. Mozas[1], V. Ortíz-Maldonado[1], R. Santacruz[2], M. Rozman[3], M. Aymerich[3], N. Villamor[3], D. Costa[3], A. Carrió[3], E. Montserrat[1]
[1]Hematology Department, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain, [2]Hematology Department, Hospital de Clínicas, Asunción, Paraguay, [3]Hematopatholgy Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: In CLL, tumor doubling time is reflected by the pace at which lymphocytes increase in blood (lymphocyte doubling time or LDT). However, since LDT is rarely available at the time of diagnosis, its role in assessing prognosis in patients in CLL is controversial.
Aims: To reassess the prognostic significance of LDT in a large series of patients.
Methods: Retrospective single-center study based on 629 patients diagnosed with CLL/SLL. LDT was measured at the time of diagnosis if prior WBC counts were available or calculated after diagnosis by linear regression analysis, usually over a treatment-free period of 2 months and including at least three WBC counts.
Results: 140 patients displayed short LDT (≤12 months) and 489 long LDT (>12 months). The median follow-up up was 13.4 years (6.1-22.5) and 11.2 years (2.2-30.9), respectively. Patients with short LDT were younger (p=0.005), had more advanced clinical stage (p<0.001), higher ALC (p<0.001), as well as increased serum LDH (p<0.001) and B2-microglobulin (B2M; p=0.035) levels and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated *IGHV* (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p=0.002). Additionally, patients with a short LDT presented more frequently mutations in *NOTCH1* (p=0.008), *ATM* (p=0.029), *TP53* (p=0.035) and a tendency to more mutations in *SF3B1* (p=0.102). The proportion of patients treated in each group was markedly different [80% *vs* 46%] as it was the median time to treatment (TTT, 1.4 *vs* 9.4 years; p<0.001). Type of treatment (mainly, chemo[immuno]therapy) did not significantly differ between both groups and there was no significant differences in response rates (ORR 59% with 29% CR *vs* 69% with 29% CR; p=0.253). Overall survival (OS) was shorter in the group with short LDT (median: 7.2 *vs* 12.2 years; p<0.001). Univariate analysis demonstrated a significant correlation between OS and advanced clinical stage, age >70 years, increased B2M and LDH (p<0.001), short LDT, increased ZAP70 and CD38, unmutated *IGHV*, and high-risk FISH genetics (del17p, del11q) (all p<0.001). Likewise, mutations in *NOTCH1* (p<0.001), *SF3B1* (p=0.027), *ATM* (p=0.028) and *TP53* (p<0.001) were associated with OS. In a multivariate analysis including clinical stage, age, LDT, *IGHV*, ZAP70, FISH cytogenetics and *TP53* mutations (*NOTCH1* and *SF3B1* mutations were not included in the analysis because of the small number of patients in whom these markers were available), a short LDT maintained its prognostic value for OS (HR 2.7 (95% CI: 1.6-4.7), p<0.001) along with age >70 years (HR 5.2 (95% CI: 3.2-8.5), p<0.001), high-risk FISH (HR 2.2 (95% CI: 1.3-3.6), p=0.003), unmutated *IGHV* (HR 2.4 (95% CI: 1.5-4.0), p<0.001), and presence of *TP53* mutation (HR 2.0 (95% CI: 1.0-3.9), p=0.041).
Summary/Conclusions: This study shows that LDT continues being an independent prognostic parameter for OS in the era of biomarkers. In contrast, LDT did not correlate with response to therapy and, accordingly, cannot be regarded as a response predictor to chemo(immuno) therapy. Finally, LDT warrants investigation in the setting of novel therapies.

E1032

INDICATIONS FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICO-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT

P. Mozas[1,*], A. Rivas-Delgado[1], T. Baumann[1], V. Ortiz-Maldonado[1], A. Navarro[2], D. Costa[3], M. Aymerich[3], N. Villamor[3], E. Montserrat[1], J. Delgado[1]

Background: Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of monoclonal CD5$^+$ B cells in the bone marrow and lymphoid tissues. International guidelines recommend initiation of treatment only in case of infiltrative cytopenia, progressive splenomegaly or lymphadenopathy, short lymphocyte doubling time (LDT), B symptoms and/or refractory immune cytopenia (IC). These criteria are based on experts' consensus and considered equally relevant for treatment initiation, even though little evidence exists concerning the relative value of each individual criterion.
Aims: To describe the clinico-biological characteristics and prognosis of CLL patients according to the criteria that prompted the initiation of first-line treatment.
Methods: We identified 530 consecutive patients with CLL who required front-line therapy from 1978 to 2014 and had their indication(s) for treatment (IfT) recorded. Massive/progressive lymphadenopathy and massive/progressive splenomegaly were grouped together as lymphoid mass (LM). Infiltrative anemia and thrombocytopenia were categorized as marrow failure (MF). As 505 patients (95%) initiated therapy due to LM, MF or both, we decided to focus on these two groups. Patients whose IfT was both LM and MF were classified as MF following the logic behind Rai and Binet staging systems.
Results: Median age of the whole cohort was 62 years (range 22-93), and 63% of patients were male. Median follow-up from first-line therapy was 64 months (range, 1-433). Half of the patients had a single IfT, while the other half had two or more. IfT were LM in 72% patients, MF in 31%, short LDT in 29%, B symptoms in 19%, and IC in 3%. Compared to patients from the LM group, patients from the MF group were significantly older, had a significantly higher β2-microglobulin level (probably due to an age-related impaired renal function), and were more frequently treated with alkylating agents than purine analogues. Conversely, patients treated due to LM had more frequent adverse prognostic characteristics, such as higher ZAP70 expression, unmutated *IGHV* genes, and 11q deletion. The median OS of the entire population was 77 months (95% confidence interval [CI]=71-83) from first-line therapy and 108 months (95% CI=102-118) from diagnosis. Indication for treatment was significantly associated (p<0.001) with a shorter OS from first-line therapy: 63 months in the MF group (95% CI: 48-72), compared to 89 months in the LM group (95% CI: 80-106). This association remained significant after adjusting for age and β2-microglobulin concentration.

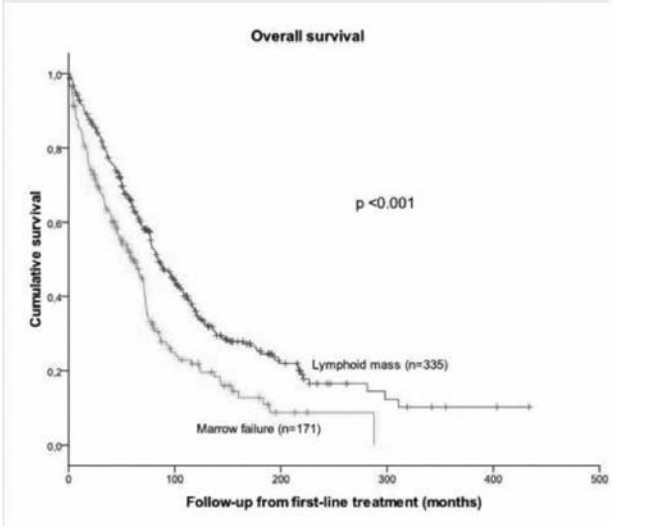

Figure 1.

Summary/Conclusions: All IfT are still regarded as equally important, although no solid evidence exists to support such statement. In our series, infiltrative cytopenia and/or progressive lymphadenopathy/splenomegaly constituted the IfT in most (95%) CLL patients. In spite of being enriched in favorable biological prognostic factors (mutated *IGHV* genes, low ZAP-70 expression and favorable-risk cytogenetics), MF patients had a shorter age-adjusted OS from first-line therapy compared to LM patients. Further studies should address whether this result also applies to patients treated with novel agents.

UNCOVERING PRIMARY TP53-DELETED CLONES WITH FISH THROUGH FACS-SUPPORTED PURIFICATION OF CHRONIC LYMPHOCYTIC LEUKEMIA LYMPHOCYTES

G. Marques[1], M. Pereira[2,3,*], J. Lima[1], R. Reis[1], A. Coelho[1], L. Jorge[1], S. Pedreiro[4], L. Ribeiro[2], A. Paiva[4], F. Rodrigues[1]

Background: The presence of TP53-inactivation in chronic lymphocytic leukemia (CLL), namely through the deletion of all or part of the chromosomal region containing its locus, is a well-established marker of poor prognosis and chemoresistance to traditional chemotherapeutic agents. Fluorescence *in situ* hybridization (FISH) is a useful tool for the detection of the deletion. Nevertheless, its sensitivity is influenced by the number of blood-cell lineages that carry the aberration; the absolute count of deletion-positive cells; and the proportion of deletion-positive neoplastic cells relative to deletion-negative neoplastic cells and non-neoplastic cells, in the whole blood or bone marrow sample. The latter issue can be minimized by purifying the sample through the selection and separation of tumor cells, using techniques such as fluorescence-activated cell sorting (FACS).
Aims: In this study, we aim to evaluate the benefit of using purified samples of neoplastic CLL lymphocytes for the detection of TP53-deletion by FISH, when compared to full samples.

Methods: We reviewed all CLL samples that were submitted for the investigation of TP53-deletion through FISH, in our Lab, between January 1st 2011 and February 28th 2017. Results obtained on tests performed on whole mixed cellularity samples were compared with results obtained directly in FACS purified CLL clonal lymphocytes.
Results: We analyzed 410 samples tested for the deletion of TP53 in our Lab during the study period. The majority of patients (63.2%) were male. Although FACS separation of neoplastic cells was only introduced within the last two years of the study period, it accounted for 39.0% of all tested samples. This poor prognostic aberration was identified in 15.8% of patients in the overall cohort, with no differences in the incidence of a positive finding between mixed cellularity samples and FACS purified samples (15.6% *vs* 16.2%, respectively, p=NS). In contrast, the average proportion of positive cells within a positive sample was markedly different between mixed cellularity samples and FACS-processed samples, increasing nearly three-fold through the purification of the sample, from 24.0±15.9% to 62.9±33.3%, p<0.001. In fact, in 57.7% of all patients who were tested after FACS separation of CLL cells, the TP53-deleted clone was larger than 50% of neoplastic clonal lymphocytes, making it the primary clone.
Summary/Conclusions: We observed that the pre-processing of the sample through the FACS-supported purification of CLL neoplastic lymphocytes revealed that the TP53-deleted clone was nearly three-fold larger than suggested by the mixed cellularity sample, increasing from an average of a quarter of all cells, to nearly two-thirds. This finding uncovered that the TP53-clone was, in fact, the primary major clone within the neoplastic lymphocyte population in the majority of patients. Considering the poor prognosis conferred by the aberration, and its impact on current treatment decisions, it is quite significant to correctly identify a primary deletion-positive clone, instead of mislabeling it as a secondary minor clone.

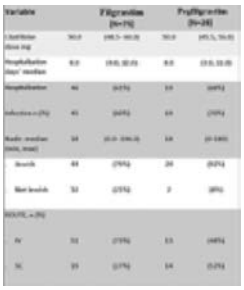
Background: Major advances in the treatment of patients with HCL were made in the 1980's after the introduction of two purine analogues: pentostatin and cladribine. Both these agents dramatically altered the clinical course and outcome of this disease and induced high response rates of 75-90%, with durable remissions and subsequent median relapse-free survival of up to 15 years. The major significant short-term toxicity of therapy with cladribine are neutropenia and neutropenic fever (NF). Based on the script data: 71% of patients experience grade 4 neutropenia (absolute neutrophil count [ANC] <500x109/l), and 42% develop NF. The latter complications may result in life - threatening infections, as well as hospitalization.
Aims: In this retrospective study, we compared the incidence and duration of neutropenia, NF and hospitalization in patients with HCL treated with cladribine followed by pegfilgrastim as primary prophylaxis *versus* daily filgrastim given "on demand "according to the absolute neutrophil count.
Methods: The study population included 202 patients with HCL, diagnosed and followed in 12 medical centers in Israel during 1985-2015. Patients were treated with cladribine, for 5-7 days given either sub-cutaneously or via intravenous infusion. Medical records were evaluated for details of disease at diagnosis, including date of diagnosis, age, sex, ethnicity,complete blood count results, and spleen size at diagnosis. The efficacy of pegfilgrastim and filgrastim was assessed by evaluating the incidence of neutropenia (defined as ANC <1000x109/l), number and length of hospitalizations due to NF, severity of infections and the number of days from the last day of therapy until recovery of ANC to >1000x109/l.
Results: Mean follow up was 7.5 years (0.1-40), with 5 and 10 years' survival of 96% and 90.62% respectively. The median age at diagnosis was 53 years, and 81.8% were males. First line therapy with cladribine was given to 159 patients (80.7%) and of these 50.3% required hospitalization for the administration of broad-spectrum antibiotics due to NF. The risk factor to develop NF was WBC< 0.6 109/l, and ANC<0.3109/l. Twenty eight patients were treated with pegfilgrastim as primaryprophylaxis 24 hours after the last day of therapy with cladribine, while 75 patients received filgastrim " on demand "due to neutropenia.Median hospitalization days, and Nadir duration was 8 and 18 days respectively in both groups (p=0.71, p=0.44).

Table 1.



Summary/Conclusions: Infectious complications post cladribine treatment, remains high, with an incidence of 50.3%. For all parameters analyzed, including the percentage of febrile patients, number of febrile days, and NADIR duration the results of primary pegfilgrastim prophylaxis and filgrastim given on demand were similar.Accordingly, we conclude that it remains the treating physician's choice to decide on which type of filgrastim to use and when to administer it.

REDUCED HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA ACHIEVING COMPLETE REMISSION TO FIRST-LINE THERAPY

S Heitner Enschede[1,*], J. Samp[1], A. Guerin[2], R. Foster[3], B. Meissner[1], A. Rokito[3], G. Gauthier[2]
[1]AbbVie, Inc., North Chicago, United States, [2]Analysis Group, Inc., Montreal, Canada, [3]Analysis Group, Inc., New York, United States

Background: Most targeted therapies in the management of chronic lymphocytic leukemia (CLL) lead to high overall response rates but complete remissions are rare. Achieving complete remission (CR) is associated with improved clinical outcomes such as longer time to progression; however little is known about the economic benefits associated with achieving CR.
Aims: The objective of the study was to compare healthcare resource utilization among CLL patients initiated on first-line treatment who achieved CR *versus* those who did not.
